THIS volume of 8vo size contains 498 pages of subject matter, with 20 illustrations, and 13 pages of Divisions and Assessment Tables, followed by the Alphabetical index. The contents are classified as follows, names of special compilers being given:—Introduction. Aluminium. II. Antimony. III. Arsenic. IV. Asbestos. V. Asphaltum. VI. Barytes. VII. Bauxite. VIII. Bromine. IX. Carborundum. X. (By R. W. Leslie) Cement. XI. Chromium and Chrome Ore. XII. Coal and Coke (By S. Sanforl). XIII. Copper (By D. H. Newland). XIV. Copperas. XV. Fluorspar (in parts F. J. Fells). XVI. Garnet. XVII. Gold and Silver (T. A. Rickard, R. H. Richards, C. H. Fulton and A. J. Jamieson). XVIII. Graphite. XIX. Iron and Steel (Fr. Hobsch, S. F. Luty and G. W. Cushing). XX. Lead (D. H. Newland and H. O. Hofman). XXI. Manganese. XXII. Monazite. XXIII. Nickel and Cobalt (By A. McCharles). XXIV. Petroleum (C. T. Deane). XXV. Phosphoric Rock and Phosphorus (C. C. Schnatterbeck). XXVI. Mercury (By D. H. Newland). XXVII. Zinc (W. Ingalls). XXVIII. Review of General Literature. Ore Deposits (J. F. Kemp). XXIX. Review of Literature on Ore Dressing (R. H. Richards). XXX. Reviews of Mining Progress in 1903. XXXI. Mining Companies.

FOREIGN IMPORT DUTIES, 1904. Prepared by the Commercial Department of the Board of Trade. Cd. 23. Eyre and Spottiswoode, London. Price 2s.

8vo VOLUME of 490 pages, being a statement of the rates of import duties levied in European countries, United States, Japan, China, and Persia upon the produce and manufactures of the United Kingdom. The rates of duty given are those in force up to November, 1904. The work includes a table of weights, measures and money, and a table of conversions of Foreign into English weight measures and money. The import duties are given under the following heads: Yarns and thread; woven manufactures; metals, unwrought and wrought; earthenware and porcelain; glass and glasswares; hides, skins and leather; india-rubber and gutta-percha; paper, & stationery and books; painters' colours and material chemicals; salt; oils, fats and resins; earthen, stone, minerals, &c.; articles of food; miscellaneous articles (including ammunition, candles, perfumery and soap).

Trade Report.

I.—GENERAL.

CANADIAN CUSTOMS DECISIONS ON ARTICLES EXEMPT FROM AND SUBJECT TO SPECIAL DUTY.

Board of Trade J., Feb. 9, 1905.

The following have been decided by the Canadian Department of Customs to be exempt from "special duty" under the Tariff Amendment Act No. 11 of 1904:—sodium bicarbonate, hydrogen peroxide, hydrozone.

The following are subject to special duty (if sold at a reduced price for export):—Writing ink, ammunition, gumite, mucilage, photographic dry plates, soap, baking powder, linoleum and oil cloth, linseed oil, paper, potassium iodide, white lead, refined sugar imported after Nov. 23, 1904 (except sugar refined in a British country entitled tariff preference by Canada).

WATER POWER USED FOR GENERATING ELECTRICITY: AMOUNT OF —.

Eng. and Mining J., Jan. 26, 1905.

The world's water-power installation, generating electricity, is approximately as follows: United States, 5,467 h.p.; Canada, 228,225 h.p.; Mexico, 18,470 h.p.; Venezuela, 1,200 h.p.; Brazil, 800 h.p.; Japan, 3450 h.p.; Switzerland, 133,302 h.p.; France, 161,343 h.p.; Germany, 81,077 h.p.; Austria, 16,000 h.p.; Sweden, 71,000 h.p.; Russia, 10,000 h.p.; Italy, 210,000 h.p.; India, 50 h.p.; South Africa, 2100 h.p.; Great Britain, 906 h.p.; total, 1,483,390 horse power.

II.—FUEL, GAS, AND LIGHT.

COAL PRODUCTION OF GERMANY IN 1904.

Board of Trade J., Feb. 9, 1905.

The subjoined particulars of the coal production of Germany in 1904, as compared with the previous year, taken from the "Nachrichten für Handel und Industrie" of the 21st January:—

	Coal.		Lignite.		Coke.		Briquettes.	
	1903.	1904.	1903.	1904.	1903.	1904.	1903.	1904.
	Tons.	Tons.	Tons.	Tons.	Tons.	Tons.	Tons.	Tons.
Russia	108,989,879	112,808,409	38,460,232	41,126,856	11,446,652	12,268,436	9,173,681	10,102,478
Austria	1,360,901	1,341,314	16,539	52,318	—	—	—	—
Germany	4,698,458	4,794,295	1,828,159	1,915,135	62,607	62,727	277,190	300,897
Other States	1,615,138	1,750,080	5,650,628	5,405,913	—	—	1,025,299	1,010,992
Total	116,664,376	120,694,098	45,955,558	48,500,222	11,509,259	12,331,163	10,476,170	11,413,467

NOTE.—The ton mentioned is the metric ton of 2,204 lbs.

The total imports of coal from the United Kingdom amounted to 5,808,032 tons in 1904, as compared with 393,828 tons in 1903 and 5,191,869 tons in 1902.

ANNUAL REPORT OF THE ROYAL COMMISSION ON COAL SUPPLIES. Part I. General Report. [Cd. 2353.] Price 4d.

This report of the Royal Commission appointed on 21st December, 1901, deals with the following subjects:—(1) the resources of our coalfields; the probable duration of our coal resources; possible economies (1) underground, (2) in the preparation of coal for sale, (3) in transportation from the collieries to the users in the United Kingdom, (4) in use; possible substitutes for coal (alcohol, natural gas, oil, water and windmill power, tides and peat); effect of exports of coal on British consumers and the Royal Navy; the maintenance under existing conditions of the competitive power of our coal mining industry with the coalfields of other countries.

Tables are appended showing:—(a) the total available

coal resources of the proved coalfields of the United Kingdom; (b) the total coal resources of the proved coalfields of the United Kingdom—exceeding 4000 feet in depth; (c) the resources of the concealed and unproved coalfields at depths less than 4000 ft.; (d) the output of coal in the United Kingdom, its pit-mouth value, the quantity shipped for foreign countries in the form of coal, coke, and patent fuel, the total quantity shipped, including coal shipped for the bunkers of steamers engaged in the foreign trade, the quantity remaining for home consumption, and its proportion per head of the population for the years 1870 to 1903.

III.—TAR PRODUCTS, PETROLEUM, Etc.

PETROLEUM: CANADIAN —.

U. S. Cons. Rep., No. 2165, Jan. 24, 1905.

The law by which a bounty of one-half cent a gallon is granted for the production of crude petroleum in Canada, came into effect on June 8, 1904, and between that date and December 1 the sum of 123,088 dols. has been paid out on 365 applications. This represented a total production of 18,063,200 gals. The bounty has greatly stimulated the industry.

PETROLEUM: CALIFORNIA —.

Eng. and Mining J., Jan. 26, 1905.

Of the 13 recognised oil districts in California four produced over a million barrels each in 1904. These were the Kern River, 17,500,000 bbl.; Coalinga, 4,544,160 bbl.; McKittrick, 1,650,000 bbl.; Los Angeles, 1,080,000 bbl. Four others report between half a million and a million each; viz., the Fullerton, 876,000; Whittier, 780,000; Santa Maria, 750,000; Newhall and Ventura, 540,000 bbl. The five remaining districts have the following record: Sunset and Midway, 376,000 bbl.; Puente, 204,000; Summerland, 80,000; Sargents, 42,700; Half Moon Bay, 1000 barrels. The total output of the State in 1904 was 28,423,860 barrels of crude oil.

PYRIDINE: U.S. CUSTOMS DECISION.

Jan. 16, 1905.

Pyridine, produced from coal tar, is dutiable at 20 per cent. *ad valorem*, as a "preparation of coal tar, not a colour or dye," under paragraph 15 of the present tariff. The assessment of duty at 25 per cent. *ad valorem*, as a "chemical compound," was overruled.—R. W. M.

IV.—COLOURING MATTERS, Etc.

INDIGO CROP OF 1904.

Chem. Trade J., Feb. 11, 1905.

The final general memorandum on the indigo crop of the season 1904, issued by the Statistical Department of the Government of India, and published by the Bengal Chamber of Commerce, states that the area under cultivation has diminished by nearly one-third since last year, and the estimated out-turn is lower by 46 per cent.

In Bengal the area sown this year is estimated at 223,100 acres, against 249,700 acres sown last year. The season was so very unfavourable that the estimated out-turn for Lower Bengal, including the minor Bihar districts, is 69 per cent., and of North Bihar 53 per cent. of a normal crop, the provincial average being 56 per cent. The yield in North Bihar may amount to 24,700 factory maunds, and in Lower Bengal, including the minor Bihar districts, to 8,310 factory maunds, giving a total for the province of 33,010 maunds. The production in 1903 was 17,630 factory maunds (3 factory maunds = 2 cwt.).

In the United Provinces the total indigo area in 1904 amounted to 74,200 acres, compared with 140,800 acres, the ascertained area of 1903, and is the lowest since the decline of this crop began. The prospects of the indigo crop were good when the first forecast was issued, but the heavy and continuous rain of July and August caused serious damage. The total out-turn of indigo is estimated at 12,000 factory maunds (Benares 5250 and Deob 6750), which is 37 per cent. below the last year's estimate. The trade figures of past years indicate that a considerable proportion of the reduced yield is consumed locally or exported to other provinces; the amount of indigo available for the Calcutta market is, therefore, likely to be considerably less than the out-turn indicated above.

In the Punjab the area under indigo continues to decline and has fallen from 74,200 to 53,000 acres. In three out of the four reporting districts, namely, Rohtak, Muzaffargarh and Dehra Ghazi Khan, heavy decreases are reported. A larger area, though still 15 per cent. below the decennial average, was sown in the Multan Division, but the yield was somewhat below the normal. The out-turn of seed is estimated at 1,673,800 sers (28,021 cwt.) and of dye at 589,700 sers (9872 cwt.).

In Madras the total area sown with indigo in the Padiyattari villages up to the end of November, 1904, is 99,800 acres, which is less than the averages of five and ten years by 49 and 63 per cent. respectively, and than the area in the corresponding period of the preceding year by 49 per cent. The decrease is marked in Guntur, Nellore, Chingleput, North Arcot, and the Deccan districts, and is attributed to scanty rains and the fall in the price of the dye.

VII.—ACIDS, ALKALIS, Etc.

BORAX; U.S. CUSTOMS DECISION.

Jan. 13, 1905.

A mixture of borax and sal soda, containing 91.65 per cent. of crystallised borax, was held to be dutiable as "borax" at 5 cents per lb. under paragraph 11 of the present tariff. Although the content of anhydrous boric acid was only 33.56 per cent., the Board held that it was in fact borax, though adulterated, and not dutiable as "borate of soda containing less than 36 per cent. of anhydrous boric acid" at 3 cents per lb. under the same paragraph.—R. W. M.

X.—METALLURGY.

MINES AND MINERALS OF CANADA.

U.S. Cons. Report, No. 2163, Jan. 21, 1905.

The report on the mining industry of Canada by the director of mines states that the total mineral products of the year were valued at 12,870,593 dols., and the wages paid amounted to 4,222,386 dols. Of the total value, 7,628,018 dols. represents products of the non-metallic class and 5,242,575 dols. metallic products. The total production of gold was 10,383 oz., valued at 188,036 dols.; the industry gave employment to 493 persons, who were paid in wages 245,490 dols. Including the cost of supplies it required an expenditure of almost 2 dols. to extract 1 dol. worth of ore. The same story is told of silver mining; the total quantity produced was 16,688 oz., valued at 8949 dols., and the wages paid out 8000 dols. The production of lead was still more unprofitable, although restricted. The amount mined was 25 tons,

valued at 1500 dols., at a cost of 5189 dols. Copper nickel properties on the whole gave excellent returns. The value of the products was 3,215,794 dols., and wages paid aggregated 872,302 dols., leaving a margin for supplies and a satisfactory profit.

The wages paid for the production of petroleum amounted to 165,700 dols., while the value of the product was 1,586,674 dols. The expansion of the cement industry is a marked feature of the mineral development of the province. The rapid growth in output is indicated by the figures supplied in the report. In 1899 the increase was 45 per cent. over 1898; in 1900 it was 38 per cent. over 1899; in 1901 it was 14 per cent.; in 1902 it was 49 per cent. over the previous year; and in 1903 it was a further increase of 33 per cent. over 1902, withstanding this remarkable expansion there imported in the year ended June 30, 1903, 2,572,088 valued at 901,063 dols., upon which the duty paid 271,004 dols. As the uses to which cement is put multiplied and the industry grown the price has fallen. It was 2.50 dols. a barrel in 1901, and 1.70 dol. in 1903. The erection of new plants is proceeding in Canada at a rate that seems to promise an era of overproduction in Ontario, with attendant curtailment or extinction of profits.

PIG IRON IN THE UNITED STATES IN 1904.

Eng. and Mining J., Feb. 2, 1905.

The total production of pig iron in 1904 was 16,493,364 gross tons, against 18,009,252 tons in 1903, 17,820 tons in 1902, 15,878,354 tons in 1901, 13,789,242 tons in 1900, 13,620,703 tons in 1899, and 11,773,934 tons in 1898. The production in the second half of 1904 was 150,157 tons more than that of the first half, the last months of 1904 showing increasing activity in production. The production of bessemer and low-phosphorus iron in 1904 was 9,098,659 tons, against 9,989,908 in 1903. The production of basic pig iron in 1904 including charcoal of basic quality, was 2,483,104 tons, against 2,040,726 tons in 1903. The productive charcoal pig iron in 1904 was 337,529 tons, against 50 tons in 1903 and 378,504 tons in 1902. The production of spiegeleisen and ferro-manganese in 1904 was 21 tons, against 192,661 tons in 1903. The productive ferro-manganese alone in 1904 amounted to 57,076 tons. One company produced 946 tons of ferro-phosphorus in 1904. The whole number of furnaces in blast on Dec. 31, 1904, was 261, against 182 on Dec. 31, 1903.

The total production, classified according to fuel used, with the number of furnaces in blast on Dec. 31, was as follows:—

	Number.	Tons made.
Coke	206	14,931,364
Anthracite	38	1,228,140
Charcoal	17	337,529
Totals	261	16,497,033

The number of furnaces reported idle at the close of the year was: Coke, 94; anthracite, 35; charcoal, 9; total, 168.

XII.—FATS, FATTY OILS, Etc.

GREASE; BROWN —. U.S. CUSTOMS DECISION.

Jan. 25, 1905.

Brown grease obtained from hogs was assessed for as "brown wool grease" at $\frac{1}{2}$ cent per lb. under paragraph 279 of the present tariff. The importer claimed it to be free of duty as a "grease commonly in soap making, &c.," under paragraph 568. It held that the evidence was insufficient to justify the claim of the importer, and also that the classification was erroneous. An analysis of the merchandise indicated it was dutiable at 20 per cent. *ad valorem* under Section 6.

"manufactured article unenumerated," but as this was not made, the assessment of duty at $\frac{1}{2}$ cent per lb. was allowed to stand.—R. W. M.

OLIVE OIL; U.S. CUSTOMS DECISIONS.

Dec. 31, 1904, and Jan. 6, 1905.

Olive oils containing 2.5 and 2.9 per cent. of free fatty respectively were held to be edible and subject to a duty of 40 cents. per gallon under paragraph 40 of the present tariff act. The claim of the importer for free import under paragraph 626, as "olive oil fit only for manufacturing and mechanical purposes," was overruled.—R. W. M.

BENZENE SOAP; U.S. CUSTOMS DECISION.

Dec. 29, 1904.

Soap composed of soap 72.4 per cent., benzol 10.8 per cent. and the balance water, and not soluble in water, was held to be dutiable at 20 per cent. *ad valorem* as a soap not specially provided for, under paragraph 72 of the present tariff. The assessment of duty at 30 per cent. *ad valorem*, as "alizarin assistant," was overruled.—R. W. M.

IV.—TANNING; LEATHER; GLUE, Etc.

OENOTANNIN; U.S. CUSTOMS DECISION.

Jan. 16, 1905.

Oenotannin, used to clarify wine, was held to be dutiable as "tannin" at 50 cents per lb., under paragraph I of the present tariff, since tannin is the component material of chief value.—R. W. M.

QUEBRACHO CHIPS; U.S. CUSTOMS DECISION.

Jan. 16, 1905.

Quebracho wood in fragments and chips is dutiable at 10 cents per lb. and 10 per cent. *ad valorem*, as "wood of chief value" under paragraph 20 of the present tariff.—R. W. M.

XVI.—SUGAR, STARCH, GUM, Etc.

SUGAR; POLARISCOPIC TEST OF — U.S. CUSTOMS DECISION.

The United States Supreme Court having denied an application for a writ of *certiorari* from the decision of the Circuit Court of Appeals, which held that the system of temperature corrections applied to the polariscopic test of sugar was correct and within the power of the Secretary of the Treasury, the protests of the importers have been uniformly overruled by the Board of General Appraisers in numerous cases.—R. W. M.

XVII.—BREWING, WINES, SPIRITS, Etc.

TARTARIC MATERIALS: EXPORTS OF — FROM ITALY.

Foreign Office Annual Series, No. 3323.

Below are given the quantities and values of the various tartaric materials exported from Italy from October 1, 1903, to September 30, 1904:

	Quantity.	Value.
	Tons.	£
Refined argols	668.5	40,100
Vicia argols	2977.5	157,800
Cie argols	3116.0	152,700
Waste	3728.0	85,800
Total	10,490	436,400

The total product the United Kingdom took 1386 tons, the United States 3459 tons, the remainder being consumed mostly on the Continent.

XX.—FINE CHEMICALS, Etc.

ACETYSALICYLIC ACID; U.S. CUSTOMS DECISION.

Jan. 17, 1905.

Acetylsalicylic acid was held to be dutiable at 55 cents per lb. under paragraph 67 of the present tariff, as a "medicinal preparation in the preparation of which alcohol is used."—R. W. M.

RHODINOL; U.S. CUSTOMS DECISION.

Jan. 13, 1905.

Synthetic oil of rose, known also as rhodinol, was held to be free of duty as "otto of roses" under paragraph 626 of the present tariff. The assessment of duty at 25 per cent. *ad valorem*, as an "essential oil" under paragraph 3, was overruled.—R. W. M.

SACCHARIC PREPARATIONS; U.S. CUSTOMS DECISION.

Dec. 14, 1904.

The United States Circuit Court reversed a decision of the Board of General Appraisers, which held that benzoic acid sulphinide and sodium benzoic sulphinide were dutiable as "saccharin." The Court decided that they were properly dutiable at 20 per cent. *ad valorem* as "preparations of coal tar not colours or dyes," under paragraph 15.—R. W. M.

RADIUM BROMIDE AND RADIUM BARIUM BROMIDE: U.S. CUSTOMS DECISION. Jan. 25, 1905.

The above articles were held to be dutiable at 25 per cent. *ad valorem* as "chemical salts," under paragraph 3 of the present tariff. The claims of the importers that they were dutiable either as a "metal unwrought" or as a "manufactured article unenumerated" were overruled.—R. W. M.

GADUOL; U.S. CUSTOMS DECISION.

Jan. 13, 1905.

The United States Circuit Court of Appeals has sustained a decision of the Circuit Court reversing the Board of General Appraisers which held gaduol to be dutiable as a "medicinal preparation, in the preparation of which alcohol is used" at 55 cents per lb. under paragraph 67 of the present tariff. The article is an extract of cod liver oil obtained by the use of alcohol. The Courts held that, in the form imported, it is not prepared for the use of the apothecary or physician, and is not dispensed in this form; hence it is dutiable at 25 per cent. *ad valorem* as a "chemical compound" under paragraph 3. The Treasury Department has acquiesced in the foregoing decision, which is now final.—R. W. M.

Patent List.

N.B.—In these lists, [A.] means "Application for Patent," and [C.S.] "Complete Specification Accepted."

Where a Complete Specification accompanies an Application, an asterisk is affixed. The dates given are (i) in the case of Applications for Patents, the dates of application, and (ii) in the case of Complete Specifications Accepted, those of the Official Journals in which acceptances of the Complete Specifications are advertised.

Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the said dates.

V.—PREPARING, BLEACHING, DYEING, PRINTING AND FINISHING TEXTILES, YARNS, AND FIBRES.

- [A.] 2188. Pearson. *See under XII.*
 .. 2192. Lacroix. Manufacture of artificial silk. [Belg. Appl., Feb. 6, 1904.]* Feb. 3.
 .. 2316. Lye and Lye. *See under VI.*
 .. 2711. Lodge and Barker. Padding machines used in dyeing and like operations. Feb. 10.
 .. 2811. Cass. Apparatus used for dyeing woollen fabrics. Feb. 11.
 .. 2873. Greenwood and Harper. Mechanism for dyeing wherein the material is continuously submerged within the dye without exposure to atmosphere during the dyeing process. [S. Appl., Feb. 12, 1904.]* Feb. 11.
 [C.S.] 3529 (1904). Pick and Erban. Bleaching and cleaning of vegetable fibres. Feb. 15.
 .. 5247 (1904). Goddard. Apparatus for dyeing warps for weaving and otherwise treating them with liquids. Feb. 15.
 .. 8288 (1904). Johnson (Badische Anilin und Soda Fabrik). Production of blue to blue-black shades on wool. Feb. 15.
 .. 11,317 (1904). Schmitt. Method and apparatus for recovering sulphur colouring matters from dye liquids and washing liquids. Feb. 15.

VI.—COLOURING WOOD, PAPER, LEATHER, &c.

- [A.] 2013. Latitte. *See under IX.*
 .. 2316. Lye and Lye. Apparatus employed in dyeing or colouring chip, chip plait, straw plait, and such like materials. Feb. 11.
 [C.S.] 9175 (1904). Kron. *See under IX.*

VII.—ACIDS, ALKALIS, AND SALTS.

- [A.] 1816. W. and J. George, Ltd., and George. Apparatus for generating sulphuretted hydrogen and other gases.* Jan. 30.
 .. 1974. Scott. Recovery of chlorine and iron from waste pickling liquors. Feb. 1.
 .. 2174. De Stucklé. Apparatus for the manufacture of alkali or alkali hydrates and zinc sulphate. [Ger. Appl., May 21, 1904.]* Feb. 3.
 .. 2463. Piva. Process for treating leucite and substances containing the same.* Feb. 7.
 .. 2564. Tcherniac. Manufacture of sulphocyanides from crude coal gas. Feb. 8.
 .. 2684. The Chalk Power Gas Synd., Ltd., and Stonham. Lime burning and the recovery of power gas as a bye-product. Feb. 9.

- [2840. Pettigrew. *See under III.*
- [S.] 24,297 (1903). Price. Processes for manufacturing nitrate, nitrite, or sulpho-nitrate or -nitrite of lime, soda, or potash. Feb. 15.
- 5540 (1904). Pauling and Pauling. Production of nitric oxide and nitric acid from air or other mixture of oxygen and nitrogen. Feb. 15.
- 8377 (1904). Leslie. Apparatus for the manufacture of carbonic acid gas. Feb. 8.

VIII.—GLASS, POTTERY, AND ENAMELS.

- [2857. Wakelin and Weston. Production of painted glass, cloisonné glass and other material from the effects of heat. Feb. 11.

—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

- [2013. Lafitte. Impregnation and coloration of timber. [Fr. Appl., March 16, 1904.]* Feb. 1.
2097. Stocker. *See under I.*
2102. Stocker. *See under I.*
2343. Heintzel and Cramer. Method of improving gypsum mortar and utilising dead burnt gypsum. [Ger. Appl., March 21, 1904.]* Feb. 6.
2467. Brown. Manufacture of mortar cement building composition. Feb. 7.
2654. Reinhertz. Treatment of earthy materials for increasing their specific gravity. Feb. 9.
2791. Stocker. Drying of various substances, such as clay, &c. Feb. 10.
2856. Drogseth. Apparatus for the impregnation of wood. [Appl. in Norway, Feb. 12, 1904.]* Feb. 11.
- [S.] 8504 (1904). Glossop. Manufacture of artificial stone. Feb. 15.
- 9175 (1904). Kron. Apparatus for impregnating and dyeing wood. Feb. 15.
- 14,183 (1904). Conti-Vecchi. Impregnation of wood with antiseptic and like substances or liquids. Feb. 15.
- 18,699 (1904). Pryor. Wood preserving composition. Feb. 15.
- 18,804 (1904). Brunson. Composition of matter for artificial stone. Feb. 8.

X.—METALLURGY.

- [A.] 1821. Sulman, Picard and Ballot. Wet separation of minerals. Jan. 30.
1916. Hendryx. Process for treating ores.* Jan. 31.
1928. Hendryx. Apparatus for treating ores.* Jan. 31.
1941. Danziger. White metallic alloy. Jan. 31.
1974. Scott. *See under VII.*
2160. Steinhart and Vogel. Treatment of tin ores. Feb. 2.
2286. Rollason. Treatment of auriferous refractory or base ores. Feb. 6.
2337. De Souza. Processes for the extraction of metallic aluminium and its alloys.* Feb. 6.
2532. Rumbold and Patchin. Process for treating complex sulphide and oxidised ores for the recovery of copper, nickel, cobalt, zinc, gold and silver. Feb. 8.
2619. Gutensohn. Means for reducing metallic oxides and their combinations to metal. Feb. 9.
2798. Sulman, Picard and Ballot. Wet concentration of ores and similar processes. Feb. 10.

- [A.] 2861. Boulton (Soc. Anon. des Mines de Bormettes, and Lotti). Treatment of lead and like ores. Feb. 11.
- [C.S.] 9384 (1904). Haddan (Elektrodon-Ges. m. b. H.). Process for obtaining metals in a pure state and apparatus for executing same. Feb. 15.
- 23,290 (1904). Mennickheim. Means for removing slag and other impurities from metal for castings. Feb. 15.
- 24,781 (1904). Blackmore. Process of reducing aluminium and other metals and making alloys thereof. Feb. 8.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

- [A.] 2001. Wood and Oaksford. Apparatus for the agitation of solutions used in electro deposition of metals. Feb. 1.
2022. Vickers, Sons, and Maxim, Ltd., and Hall. Electric accumulators or secondary batteries. Feb. 1.
- [C.S.] 4512 (1904). Nehmer. Generating electricity by the use of moist chemicals which are mechanically pressed upon zinc. Feb. 8.
- 12,507 (1904). Thompson (Chem. Elekt. Fabrik Prometheus). Production of electrical resistance bodies from amorphous or crystalline carbide of silicon or boron, or of silicon or other like suitable materials. Feb. 8.
- 26,948 (1904). Mills (Edison). Storage batteries. Feb. 15.

XII.—FATTY OILS, FATS, WAXES, AND SOAP.

- [A.] 2139. Jarvis and Jarvis. Composition of lubricants.* Feb. 3.
2188. Pearson. Recovery of fatty matters from the effluents of wool washing and other processes. Feb. 3.
- [C.S.] 9638 (1904). Nusch (Chem. Werke G. m. b. H. vorm. Dr. C. Zerbe). Manufacture of a soap preparation for use in preventing poisoning by compounds of lead, copper, arsenic, mercury, and other metals. Feb. 15.
- 20,474 (1904). Boulton (Burton). Process of manufacturing hydroxystearic acid from oleic acid. Feb. 15.

XIII.—PIGMENTS, PAINTS; RESINS, VARNISHES; INDIA-RUBBER, ETC.

(A.)—PIGMENTS, PAINTS.

- [A.] 1822. Restiaux. Paint. Jan. 30.
- [C.S.] 7963 (1904). Newton (Bayer and Co.). Manufacture of colour lakes. Feb. 8.

(B.)—RESINS, VARNISHES.

- [C.S.] 7256 (1904). Shaw. Machinery for printing the pattern on linoleum, oilcloth, &c. Feb. 8.

(C.)—INDIA-RUBBER.

- [A.] 2234 Henry and Lugo. Processes and methods of manufacturing artificial india-rubber and vulcanites. Feb. 4.
2575. Gubbins. Method of, and apparatus for, treating rubber waste and the like. Feb. 8.
2655. Steenstrup and A/S Gummi-Regenerations Societet. Process of devulcanising india-rubber.* Feb. 9.
- [C.S.] 15,436 (1904). Kittel. Process for regenerating vulcanised waste rubber. Feb. 15.

XIV.—TANNING, LEATHER, GLUE, SIZE, Etc.

- [A.] 2070. Lambert. Glue, and process for manufacturing the same. Feb. 2.
 „ 2441. Hunter. Process for treating bone.* Feb. 7.
 „ 2455. Hunter. Process for treating bone.* Feb. 7.
 [C.S.] 7761 (1904). Taylor. Treatment and finish of leather. Feb. 15.
 „ 363 (1905). Lake (Schœdlkopf, Hartford and Hanna Co.). Depilatory composition. Feb. 15.

XVI.—SUGAR, STARCH, GUM, Etc.

- [C.S.] 2928 (1904). Naudet. Process and apparatus for the diffusion and extraction of saccharine juices. Feb. 15.

XVII.—BREWING, WINES, SPIRITS, Etc.

- [A.] 2738. Free. Malting apparatus. Feb. 10.
 [C.S.] 3196 (1904). Vignier. Fermentation of wines, wash, or beer, and the making of yeast for distillers. Feb. 15.
 „ 20,031 (1904). Gaskell and Day. See under I.

XVIII.—FOODS; SANITATION, WATER PURIFICATION; & DISINFECTANTS.

(A.)—FOODS.

- [A.] 2020. Simpson and Jackson. Milk products and process and apparatus for producing same. Feb. 1.
 „ 2166. Stern. Process of preparing non-alcoholic fruit juices.* Feb. 3.
 „ 2176. White. Treatment of farinaceous substances.* Feb. 3.
 „ 2535. Yates, and Jas. Robertson and Sons. Fruit juice products. Feb. 8.
 [C.S.] 8129 (1904). Fürst. Dietetic food preparation. Feb. 15.
 „ 26,623 (1904). Mélotte. Centrifugal cream and other liquid separators. Feb. 15.
 „ 26,905 (1904). Weitzmann. Process for refining and purifying coffee. Feb. 15.

(B.)—SANITATION; WATER PURIFICATION.

- [A.] 1776. McLean and Paterson. Process of treating and utilising sewage.* Jan. 30.

- [A.] 2219. Hamilton. Compound for removing scale from boilers.* Feb. 4.
 „ 2430. Bell. Anti-incrustation fluid for steam boilers. Feb. 7.
 [C.S.] 6516 (1904). Beckett. Water purifying apparatus applicable also to other liquids. Feb. 8.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES, AND EXTRACTS.

- [A.] 2031. Imray (Meister, Lucius and Brünig). Manufacture of dialkyl barbituric acids. Feb. 6.
 „ 2304. Oberländer and The Alliance Chemical Co. Ltd. Manufacture of *o*-toluene sulphochloride. Feb. 6.
 „ 2348. Johnson (Badische Anilin und Soda Fabrik). Manufacture of new derivatives of aldehydes and obtainment of the sulphite salts in the manufacture. Feb. 6.
 „ 2566. Zimmermann (Chem. Fabr. auf Aetien, von E. Schering). Manufacture of dialkylbarbituric acids. Feb. 8.
 „ 2666. Newton (Bayer and Co.). Manufacture of pyrimidine derivatives. Feb. 9.
 „ 2787. Mayer. Method of preparing diethylmalonurea. (Ger. Appl., June 17, 1904.)* Feb. 9.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

- [A.] 1906. Davidson. Preparing colour sensitive plates for a process of colour photography. Jan. 31.
 [C.S.] 24,774 (1904). Bry. Films for photography. Feb. 8.

XXII.—EXPLOSIVES, MATCHES, Etc.

- [A.] 1940. Gribble. Manufacture of a new explosive. Jan. 31.
 „ 2776. Centralstelle f. Wissenschaftlich-Techn. Untersuchungen Ges. m. b. H. Manufacture of nitro-glycerine. [Ger. Appl., Feb. 12, 1905] Feb. 10.
 „ 2859. Upton. Explosive compounds. Feb. 11.
 „ 2875. Thompson (Saginaw Match Co.). Lucifer matches. Feb. 11.
 [C.S.] 7893 (1904). Wetter (J. D. Riedel). Sulphur compounds and priming or igniting composition suitable for the manufacture of matches. Feb. 15.
 „ 837 (1905). Jacob. Matches. Feb. 15.

JOURNAL OF THE Society of Chemical Industry.

A RECORD

FOR ALL INTERESTED IN CHEMICAL AND ALLIED MANUFACTURES.

ISSUED TWICE A MONTH.

THE JOURNAL.

Past Presidents :

Mr Henry E. Roscoe, B.A., D.C.L., LL.D., Ph.D., F.R.S.	1881—1882.
Sir Frederick A. Abel, Bart., K.C.B., G.C.V.O., D.C.L., D.Sc., F.R.S.	1882—1883.
Walter Weldon, F.R.S.	1883—1884.
V. H. Perkin, LL.D., Ph.D., F.R.S.	1884—1885.
J. K. Muspratt	1885—1886.
David Howard	1886—1887.
Mr James Dewar, M.A., LL.D., F.R.S.	1887—1888.
Adwig Mond, Ph.D., F.R.S.	1888—1889.
Sir Lowthian Bell, Bart., F.R.S.	1889—1890.
E. Rider Cook	1890—1891.
Emerson Reynolds, M.D., F.R.S.	1891—1892.
Mr John Evans, K.C.B., D.C.L., LL.D., Sc.D., F.R.S.	1892—1893.
E. C. C. Stanford	1893—1894.
E. Thorpe, C.B., LL.D., Sc.D., Ph.D., F.R.S.	1894—1895.
Thomas Tyrer	1895—1896.
Edward Schunck, Ph.D., F.R.S.	1896—1897.
Frank Clowes, D.Sc.	1897—1898.
George Bellby	1898—1899.
F. Chandler, D.Sc., M.D., Ph.D., LL.D.	1899—1900.
Mr Jos. W. Swan, D.Sc., M.A., F.R.S.	1900—1901.
Ivan Levinstein	1901—1903.
Mr W. Ramsay, K.C.B., D.Sc., LL.D., F.R.S.	1903—1904.

† Deceased.

Publication Committee :

The President.

Julian L. Baker.	Charles A. Kohn, M.Sc., Ph.D.
G. Beilby.	Ivan Levinstein.
J. Carter Bell.	J. Lewkowitsch, Ph.D.
Joseph Bernays, M.I.C.E.	A. R. Ling.
H. Brunner.	W. Macnab.
Edw. Divers, M.D., D.Sc., F.R.S.	N. H. Martin.
Sir John Evans, K.C.B., F.R.S.	B. E. R. Newlands.
T. Fairley.	John Pattinson.
Prof. A. G. Green.	Prof. W. J. Pope, F.R.S.
Samuel Hall.	F. B. Power, Ph.D.
John Heron.	Prof. H. R. Procter.
D. B. Hewitt, M.D.	Sir Wm. Ramsay, K.C.B., F.R.S.
Prof. W. R. E. Hodgkinsoo, Ph.D.	Roberton Redwood, D.Sc.
E. Grant Hooper.	Walter F. Reid.
David Howard.	John Spiller.
Julius Hübnér.	W. S. Squire, Ph.D.
Prof. A. K. Huntington.	L. T. Thorne, Ph.D.
Wm. Kellner, Ph.D.	Thomas Tyrer.

COUNCIL FOR YEAR ENDING JULY 1905.

President : Wm. H. Nichols, M.S., LL.D., D.Sc.

Vice-Presidents :

Mr P. Phillips Bedson.	Ivan Levinstein.
Regil Coblenz.	Max Muspratt.
Mr W. R. E. Hodgkinson.	T. J. Parker.
Mr J. Hooper.	Dr. F. B. Power.
David Howard.	Sir Wm. Ramsay, K.C.B., F.R.S.
	Thos. Tyrer.

Ordinary Members of Council :

Mr Grossmann.	B. E. R. Newlands.
Mr Guttman.	Prof. W. J. Pope, F.R.S.
Mr Mingway.	Dr. Roberton Redwood.
Mr W. R. Lang.	Walter F. Reid.
Mr Lewkowitsch.	Frank Scddler.
Mr Martin.	Dr. W. S. Squire.

Sectional Chairmen and Secretaries :

CANADIAN.	
Mr J. Smale.	Alfred Burton.
LIVERPOOL.	
Mr Carey.	W. R. Hardwick.
LONDON.	
Mr Gordon Salamon.	Julian L. Baker.
MANCHESTER.	
Mr Carter Bell.	Julius Hübnér.
NEWCASTLE.	
Mr T. Dunn.	F. C. Garrett.
NEW YORK.	
Mr Russell W. Moore.	Dr. H. Schweitzer.
NOTTINGHAM.	
Mr Wood.	S. R. Trotman.
SCOTTISH.	
Mr Thomson.	Dr. Thos. Gray.
SYDNEY, N.S.W.	
Mr A. Liversidge, F.R.S.	T. U. Walton.
YORKSHIRE.	
Mr H. R. Procter.	Thos. Fairley.

Honorary Treasurer :

Samuel Hall, East London Soap Works, Bow, E.

Honorary Foreign Secretary :

Dr. Ludwig Mond, F.R.S.

General Secretary : Charles G. Cresswell.

Palace Chambers, 9, Bridge Street, Westminster, S.W.

Telegraphic Address : 59, Palatable, London.

Editor :

Watson Smith, 34, Upper Park Road, Haverstock Hill, N.W.

Official Notices.

COMMUNICATIONS.

Authors of communications read before the Society, or any of its Local Sections, are requested to take notice that under Rule 43 of the Bye-laws the Society has the right of priority of publication for three months of all such papers. Infringement of this Bye-law renders papers liable to be rejected by the Publication Committee, or ordered to be abstracted for the Journal, in which case no reprints can be furnished to the author.

ANNUAL GENERAL MEETING, 1905.

The Annual General Meeting will be held in London in July next, and the proceedings will commence on Monday, July 10th. Full particulars will appear later.

THE BRITISH SCIENCE GUILD.

The British Science Guild, which was founded some months ago by Sir Norman Lockyer, with the object of bringing home to the people of this country the necessity of applying scientific methods to all branches of human activity, has now published a first list of its members, which includes Professor Atfield, Dr. James Bell, Sir John Brunner, Professor Church, Sir William Crookes, Professor E. Divers, Dr. Gore, Dr. Griffiths, Professor Japp, Professor Liversidge, Professor Meldola, Mr. Müller, Mr. Neville, Professor Odling, Mr. Pedler, Professor Pope, Sir W. Ramsay, Mr. Shenstone, Professor Wertheimer, Mr. Whetham, and Professor Sydney Young.

One of the principal aims of the Guild is the promotion and extension of the application of scientific principles to industrial and general purposes—an object closely allied with that of the Society of Chemical Industry. The education, not only of the classes interested, but of public opinion in general, on this subject, is very desirable, and, though its progress may be slow, perhaps no surer means can be devised than that of enlisting in a single organisation all those whose sympathies are in favour of the application of exact methods in every department of life.

The annual subscription to the Guild is 2s. 6d., with an entrance fee of 2s. 6d., payable to Lady Lockyer, 16, Penywern Road, S.W. Life member's subscription is £2 2s. Information may be obtained from the Honorary Secretary, Mr. C. Cuthbertson, 9, York Terrace, N.W.

Changes of Address.

Baker, Arthur, 1/o 313; 90, Blackburn Road, Darwen, Lancashire.

Borkhardt, Dr. G. A., 1/o Romania; Pragerstrasse 12, Wilmersdorf-Berlin, Germany.

Campion, A., 1/o Cooper's Hill; Laboratory, 141, Wellington Street, Glasgow.

Cerasoli, A., 1/o West Kensington; c/o Dr. L. Mond, 18, Avenue Road, Regent's Park, N.W.

Chrystal, W. J.; all communications to 7, West George Street, Glasgow.

Conner, Arthur B., 1/o Niagara Falls; 1070, Fort Street West, Detroit, Mich., U.S.A.

De Blois, W. H., 1/o Syracuse; c/o Pulaski Mining Co., Pulaski, Va., U.S.A.

Ermen, W. F. A.; Journals to 10, Marsden Street, Manchester.

Feilmann, Dr. E., 1/o London; c/o Jno. Feilmann and Co., Ltd., 11, Short Hill, Nottingham.

Gallivan, Frank, 1/o Brooklyn; 113, Third Street, So. Boston, Mass., U.S.A.

Grandage, H., 1/o Bradford; Bassishaw House, Bassall Street, London, E.C.

Harrison, G. Herbert, 1/o Hagley; c/o Electrol-Alkai Co., Ltd., Middlewich, Cheshire.

Harrison, G. King, 1/o Hagley; retain Journals.

Hartmann, E. E., Box 154, and (Journals) 302, Box Buildings, Honolulu, Hawaii.

Heilemann, W. H., 1/o Elwell; Journals to Cambridge, Iowa, U.S.A.

Hudson, Albert W., 1/o Mexico; Yampa Smelting, Bingham Canyon, Utah, U.S.A.

Jones, G. Cecil, 1/o Manningtree; Stour Villa, Mist-Essex, Brewer's Chemist.

Lambert, Walter S., 1/o Morriston Place; Vardre Road, Clydach, R.S.O., Glamorgan.

Lange, Dr. M., 1/o Crumpsall; 66, Grafton Street, C.-on-Manchester.

Napper, S. S., 1/o Leeds; 144, Highbury New P., London, N.

North, E. Gordon N., 1/o Spain; retain Journals.

Prochazka, John, 1/o New York City; c/o Central 1-stuff and Chemical Co., Newark, N.J., U.S.A.

Smart, Bertram J., 1/o Vambery Road; 37, Barby Road, Plumstead, S.E.

Smith, Alf. B., 1/o Whiteley House; Ryecroft, Glos., Derbyshire.

Smith, Arthur, Town End Chemical Works, Bran-Leeds (correction).

Smith, Francis P., 1/o Elizabeth Street; Room 190-194, Bowery, New York City, U.S.A.

Smith, R. Watson; Journals to P.O. Box 85, Knig-Transvaal, South Africa.

Souther, Henry, 1/o Capitol Avenue; Hartford, Co., U.S.A.

Watt, Francis L., 1/o Epping; 10, Northcote Chambl-Reihy Lane, Circular Quay, Sydney, N.S.W., Austr.

Wells, Jas. G., 1/o Burton; c/o Groves and Whit-Ltd., Salford, Manchester.

Weston, David B., 1/o Sharon; 357, Harvard St., Cambridge, Mass., U.S.A.

Williams, Prof. W. Carleton, 1/o Sheffield; Broomgre-Goring-on-Thames.

Young, A. H. Innes, 1/o Germany; Carlton, Le-Sutton, Chester.

CHANGE OF ADDRESS REQUIRED.

Rücker, Dr. Hermann von; 1/o 13 Post Strasse, 1., Bavaria.

Death.

Ferrell, Jos. L., 2220, Race Street, Philadelphia, U.S.A.

London Section.

Meeting held at Burlington House, on Monday,
February 6th, 1905.

MR. A. GORDON SALAMON IN THE CHAIR.

THEORY OF DYEING.

PART II.*

PSEUDO- AND DESOLUTION.

BY W. F. DREAPER, F.I.C., ETC.

In connection with the attractive values of fibres, &c., dyes, acids, and other substances, the investigations of Linder and Picton (J. C. S., 61, 148 and 1895, 63), and others, which are mentioned in this paper, seem to indicate a clearer explanation of the action of dyeing than we are at present before us. Linder and Picton's work on pseudo-solution seems to have been overlooked by those interested in this subject, or else its value has not been realised in its application to these phenomena. The old dividing line between solution and suspension has disappeared. The difference between the two states is only one of aggregation. Arsenious sulphide can exist in such a fine state of division or suspension that it easily passes through a porous pot. The action of metallic salts on these "solutions" of arsenious sulphide is an interesting one. In their action, these salts divide themselves into sharply defined groups, according to the metals they contain. Tervalent metals have the highest coagulating power. Bivalent metals only possess 1/10th of this action, and univalent metals 1/500th part. This difference even holds with the same metal when it varies in valency. If this action is studied in detail, the results are even more instructive.

When barium chloride is used as a precipitating agent, barium is carried down, and the chlorine remains in solution. In the figures given, 10 per cent. of the barium present is removed in this way. The actual nature of the reaction is indicated further on. Similar results are obtained with calcium chloride. The metal is held almost severe washing, but another metal in solution will replace it. This action is a reversible one, depending on the proportion of the second salt in solution. It is, therefore, a case of mass action. Calcium and cobalt will, in instance, both act in this way. They both precipitate sulphide, yet each can replace the other, if present in sufficient quantity in the solution.

Grimaux (Comptes rend., 98, 1434) pointed out that a large proportion of sodium chloride at 100° is necessary to precipitate a specially soluble solution of silica he prepared. He does not indicate that the salt was decomposed, and we do not know whether such an action takes place in this case. He considered that the action was a hydrating one. It is known, however, that in some cases the presence of a salt has the opposite effect (Tomassini, Comptes rend., 99, 87).

The presence of a salt is not necessary to produce this precipitating action. Separation may take place by dyeing in some cases. Antimony trisulphide is entirely separated in this way. Albumin is not, or if so, the action is reversible one (Lubavyn, J. Russ. Chem. S., 21, 397). Blake (Amer. Journ. Sc., 16, 381) also denies that the precipitating action of salts is a universal one.

Colloidal gold precipitated by barium salts does not carry down with it any appreciable amount of the salt. In this case, however, it may be that the gold is no longer in the solid state.

These quantitative experiments may, from their nature, be a disturbing influence on any chemical theory of dyeing, when we consider that the action is not an equilibrium one, but is directly connected with, and governed by, the valency of the precipitating metal.

Regarding this arsenious sulphide solution as equivalent to an "artificial fibre substance," an affinity which is

able to disturb a system like a solution of barium chloride in this way may clearly take the place of a so-called chemical action; and give rise to a theory of dyeing which may replace the usual chemical one. If we can have such an action with barium chloride, a similar action with a basic hydrochloride, or even a sulphonic acid salt, is quite possible. Also, the experiments of Mills indicate that in mixtures of dyes, each dyestuff is absorbed in proportion to its own mass, and inversely as the mass of the other colour.

Linder and Picton, experimenting with porous pots, and such basic dyes as Hofmann's Violet and Magenta, found that these dyes were non-filterable. The particles of these dyes in solution are so small that they do not scatter light, and according to the scale of sizes adopted for arsenious sulphide solutions, they should have filtered readily. By separate experiments, they noticed that broken pieces of the same porous material, placed in the dye solution, absorbed the dyes. They did not, however, carry the experiments to their logical conclusion, and recognise, as we now know, that decomposition also takes place.

We probably have here a fibrous surface, of a slightly soluble nature, and, therefore, in a state of pseudo-solution, playing a similar part to the arsenious sulphide. The basic hydrochloride is decomposed into a basic salt, or even the base itself, either of which is very insoluble. The particles are thus degraded in the scale of solubility, and remain fixed in the colloid substance.

I am aware that recently (Suida, Ber. der K. Akad. d. Wissen. in Wien, 1904, 113, 725) attempts have been made to confirm the chemical theory of dyeing, on the grounds that only basic dyes are precipitated by silica and acid silicates. The action, however, is probably caused by the relative instability of the hydrochlorides, as compared with the sulphonic acid salts.

We find indeed that acids are absorbed by silica, and the absorption of acids and salts is also proportional to the degree of hydration (von Bemmelen, J. für. Chem., 23, 324), in this case. Yet this same fact is put forward to prove that the specific attraction of (hydrated) silica for basic dyes is a function of, and due to, the presence of OH groups. But it is equally the cause of the absorption of acids. $\text{SnO}_2 \cdot 2.3\text{H}_2\text{O}$ also will absorb more acid than $\text{SnO}_2 \cdot 1.2\text{H}_2\text{O}$ (Gorgan, Am. Chem. and Phys., 3, 66). The collected evidence on this point is, therefore, distinctly against, and not for, a chemical theory.

Dyeing a porous material in mixtures of, say, alcohol and water, should give interesting results, and this will be undertaken. It is interesting to note that many dyes are easily removed from wool by alcohol containing 5 per cent. of water, but are quite insoluble in either absolute alcohol or water (Pekoring).

Sodium chloride has a direct action on arsenious sulphide solution. It becomes non-filterable. The particles are, therefore, degraded in the scale of solution. This is interesting from the dyeing point of view. It indicates the action of such salts on "direct" dye solutions. It also shows, as Linder and Picton have pointed out, that this coagulating action increases the size of all the aggregates present. The "direct dye" aggregates are, therefore, degraded in the scale of solution, and therefore increased in size. This will be directly determined by the percentage of salt present in the solution.

The experimental results which follow lead me to put forward the following law:—"Within certain limits of concentration, and when once an equilibrium has been established, and in the case of a solution where this action is a reversible one, the aggregates in any solution system are of equal size." This agrees with the views I put forward some months ago (Chem. News, 90, 53 and 179).

With these larger aggregates we get increased dyeing effect in this case. The size of the dye aggregates will, therefore, be determined by:—

- (1) Some mutual attraction of the dye molecules for one another, or else the osmotic pressure of the solution.
- (2) Solvent action of the solution, or the relative attraction of the solution molecules for those of the solute.

An equilibrium being established between these two forces.

* Part I. of this paper appeared in this J., 1894, 95—101.

The fact that the molecular weight of the aggregates increases with the amount present, and that the number of double molecules of nitrogen peroxide varies with different solvents, lends indirect support to this theory for pseudo-solutions. Aggregation in the latter case also decreases with increased temperature, which might be anticipated.

In the case of a true solution, the relative attractions between the solvent and solute molecules are small. In the case of a pseudosolution a balance is held between this and either the attraction of the solute molecules for one another, or the condition of intermolecular strain of the solvent.

At certain points of a curve obtained with mixtures of alcohol and water, breaks have been observed (Mendeleff, *J. Chem. Soc.*, 1887, 792). It is suggested that these are the relative strengths at which the system arranges itself into definite order, due to an accurate balancing of these forces, which under these conditions seem to have a definite direction. This balance point is even into the solid state, and gives what we term definite hydrides.

The substances said to most readily form complex molecules are those containing OH, COOH, or CN groups.

Although in practice we are confined to one solvent, yet by the addition of acids, salts, &c., we can modify its physical properties towards dyes in a remarkable way. The action, for instance, of excess of acids on solutions of acid dyes may induce aggregation. At any rate, the chemical theory quite fails to explain the action of these substances on the rate of dyeing. The relative value of "assistants" will, therefore, be a measure of the modification of the pseudo-solution state of the dye. Their influence on the fibre state will be considered later on. From this point of view there will clearly be a point of maximum absorption, and then, possibly, a reverse action due to the aggregates being too large to enter the fibre system. This point may never be reached in practice. The dye may be thrown out of solution instead.

Still arguing from these sulphide experiments, the increased action of strong solutions is easily explained.

My second law, founded on these experiments, is that:—"The aggregates in a stronger pseudo-solution are larger in direct relation to the number of molecules present, and that, when once a certain point is reached, they increase in size rather than in number." This point of molecular "saturation" is either a function of the intermolecular space, or else of the attraction of the solution for the solute.

We have therefore alternative means of increasing the size of aggregates, by increasing strength of solution, or by addition of salts, &c., which either act by partly neutralising the molecular affinity of the solvent, or reducing the available molecular space, or both.

When these aggregates reach a certain size, their relations to the solvent assume a new phase. A critical point is reached when it is easier for part of the mass of the solute to be thrown out than for it to remain in the system. We then get actual precipitation and a rearrangement in size of particles.

In the case we have to deal with here, with increased temperature we get reduced size of aggregates and therefore more of them, and a higher point of saturation. This may be due to the increase of volume in the solution, and consequent increased volume of the inter-solution space.

It is suggested that all substances, in passing from the solution to the solid state, go through a state of progressive aggregation, whether they take the crystalline or amorphous form. This may either help, or prevent the former state according to circumstance. It is probably at this stage that salts are held so tenaciously by some precipitates.

I base these conclusions primarily on the fact that Linder and Ficton have shown that a 4 per cent. solution of arsenious sulphide is non-filterable and on the experiments which follow.

If we accept the above laws, we arrive at a simple explanation of the "one bath" method of dyeing. So far as I know no explanation of this process has been attempted. The case of logwood black is taken as typical. The dye solution consists of a logwood iron lake, which is dissolved in a weak solution of oxalic acid. The particles

of this lake in its ordinary condition are so large that the form a precipitate. They are outside the limit of pseudo-solution. This lake is soluble in oxalic acid. In some way or other, the aggregates are reduced in size and are able to enter the system of the fibre. Under these conditions, as explained further on, these reduced aggregates are once more degraded and held in the fibre substance. Ultimately, an equilibrium is established in which the lake is insoluble in the fibre and soluble in the solution. With an increased percentage of oxalic acid, a fair perfect solution may be obtained. The size of the aggregates may become so small, that they are not easily degraded by the fibre, and a reverse dyeing action will set in. This actually occurs in practice.

Again, when we have this acid solution, we can increase the size of the aggregates by reducing the percentage acid present, or by increasing the amount of lake present. Both these methods answer in practice. The action is a reversible one. The colour of the liquid changes with the addition of more acid, and is also subject to reversal.

The reversibility of this process is a necessary adjunct to the above laws of size. The fact that the lake is brown in solution and black in the fibre also shows that the state of aggregation is greater in the latter. Even if dissociation occur in acid solution, which is not upheld by the writer, the effect is still the same.

There is no hard and fast line between pseudo-solution and the solid state. The existence of liquid crystals also confirms this. This theory of the constant size aggregates in pseudo-solution may also be tested by some recent experiments on dyeing with indigo (Binz and Bing, *Zeit. f. angew. Chem.*, 25).

It has been pointed out that an increase in alkalinity gives a corresponding decrease in colour intensity on the fibre. Addition of neutral salts does not intensify the colour, so long as the alkali is not present in excess. The presence of excess, the addition of salts is a direct cause and darker shades are produced on the fibre; 1.8 per cent. NaCl will double the percentage of indigo fixed. In the presence of a large excess of alkali, the effect produced by the salt is reduced.

The above theory will explain the action of the salt and alkali, especially when we know that the latter is not fixed on the fibre, but only the indigo white. (Georgievich, *Der Indigo*, 1892, 55.) The action varies with the size of aggregates as determined by the relative proportion of alkali and salt. In this way, a satisfactory state of the fibre, and point of maximum effect, due to aggregation may be made to coincide and produce the best dye effect.

As a third example, the absorption of certain amines in a state of pseudo-solution or suspension, by silk and wool is given. Naphthylamine, (Pokorny, *Bull. Soc. Ch. Mulin*, 1893, 282) if dissolved in a small quantity of alcohol and poured into water, will impregnate wool at ordinary temperatures. This action would almost probably take place with mercerised cotton. From the "amido acid" theory point of view, this might indicate chemical action, but such is not the case.

The proportion of alcohol to water determines the percentage of amine absorbed. With the above amine the amount absorbed increases with the alcohol, as it increases from 5 to 30 per cent. Beyond this a reverse action sets in. Once more this theory offers a simple explanation, depending on the size of aggregates and the limit of fibre action, or absorption.

It may be noticed at this point, that these experiments have a direct bearing on the phenomenon known as osmotic pressure. There is undoubtedly some connection between this and the size of aggregates in a pseudo-solution. It is not correct to say that the difference between a crystalloid and a colloid may be ascertained by the accompanying phenomena of reduced freezing point and increased boiling point. There is no hard and fast line between the two, any more than there is between a crystalloid and a colloid in the solution state. It is simply a question of aggregation.

Rowney's water colour indigo, (finely ground) gave slight osmotic pressure in Adies apparatus (L. and F.) but ordinary indigo with larger particles gave none. In the same way, it may be expected that a colloid solution

ndigo (Möhlau and Zimmermann's method) would give a higher figure still. The osmotic pressure of substances in pseudo-solution should be a measure of their state of aggregation, if the other conditions are identical. It should be a measure of the relative attraction between the molecules of the solvent and solute.

Osmotic pressure has been found to decrease in many concentrated solutions (Traube, Phil. Mag., 1904, 8, 158). It would follow if we assume increased aggregation in stronger solutions and a corresponding decrease in the attraction between the solution and solute, as explained above.

The latest results seem to show that the theoretical conclusions of van t'Hoff and others, connecting osmotic and conductive phenomena directly with osmotic pressure, require modification. With an extension of the experimental work to other solvents than water, serious discrepancies have come to light. In many cases, osmotic pressure indicates association, and the electric phenomena dissociation. The cause of osmotic pressure is not understood, nor can it, I believe, be brought to agree with any dissociation theory. The cause of this phenomenon will, I believe, be found when these pseudo-solution effects are more closely studied. For instance, in the above case, the particles of indigo must not be too large. If no osmotic pressure is observed; the particles cannot occupy the intermolecular space. When the size of the aggregates is reduced gradually, until they become monomolecular, they correspondingly occupy this space and the solution system more or less perfectly as the case may be; but a corresponding state of strain is indicated by the increase in volume is a direct result.

With this closer contact between the molecules of the solution and solute, we have an increased attraction coming into play, but this is not of so definite an order as some, at least, of the molecules do not pass on, being acted by fresh units of the solvent.

His condition of migration was first put forward by Thomson, and developed by Maxwell. Given this state I would suggest that osmotic pressure is not so much a question of mere migration as suggested by Poynting, as of direct attraction, and the tendency to relieve local molecular strain, and set up a normal condition of equilibrium over the entire system.

In strong solutions, aggregation comes in rather than multiplication of units, which is resisted by the solution. An actual reverse in osmotic pressure may take place as the aggregates are gradually withdrawn from the solution state.

The reason why the weaker solution will diffuse into the stronger one is due to the greater mobility of the former. This also indicates association. Pickering's experiments with alcohol and water mixtures clearly indicate this. Either alcohol or water will diffuse into a mixture of the two, but the reverse action will not take place. The theory of migration of individual molecules, from whatever cause, is a necessary adjunct to the law of equilibrium in pseudo-solutions. It does not, however, seem to be necessary to assume that these roving molecules suffer dissociation. The fact that these molecules are in a state of greater freedom is against this idea.

To return more directly to our subject. This attraction of colloids for substances in solution seems to depend on the relation between the size of aggregates and the state of the fibre. A case of this action is seen in the estimation of tannic acid by "collin" (Dreaper, Chem. News, 111); collin will not precipitate gallic acid, but when added in the scale of solution by tannic acid it will do readily.

The experimental data available concerning the absorption of acids, phenols, &c., alone and in mixtures, shows how difficult or even impossible it is to accept any chemical theory of dyeing.

For instance, Gardner and Carter (J. Soc. Dyers and Colourists, 1898, 143) have shown that the relative absorption of different aromatic phenols by cotton varies between 100 per cent. and zero. The results obtained should be related against solubilities. Cotton saturated in a 0.2 per cent. solution of tannic acid will still absorb tannic acid in a 0.2 per cent. solution. This also indicates a reversal in strong solutions, and the inference is that

this too is due to aggregation. The state of aggregation or attraction by the cotton fibre in this case seems to be just balanced by a 0.02 per cent. solution, for in this it begins to lose tannic acid again (Koeberlin). It is shown also that in the presence of acetic acid the absorption of tannic acid is greatly increased (Gardner and Carter). How can this possibly indicate any chemical action?

Surface Concentration.—It has been shown by J. J. Thomson (App. of Dynamics to Phys. and Chem., 241) that, on dynamical grounds, the most stable arrangement of any solution will be accompanied by minimal surface energy. I wish to apply this to the action of dyeing. It seems also to agree with the above ideas on osmotic pressure.

In most cases the surface tension of the surface separating a solution from air increases with the amount of salt in it, and for a similar reason, salts are more soluble in equilibrium solvents than in bulk. In the case of potassium sulphate, the increased solubility in the case of graphite or microschium is nearly 25 per cent. If we apply this to the fibre state, we may expect a concentration of dye in the pores of the fibre, and this will lead, in the case of pseudo-solutions, to larger aggregates. As the salt in solution will also be concentrated, the dye may even be thrown out of solution and replaced by other smaller aggregates from the general solution. The experiments of Gore (Byghm. Nat. Hist. and Phil. Soc., IX., 1, 1893) confirm this. For instance, all the acetic acid in a dilute solution may be removed by filtering through fine white sand.

The following results, chosen at random from this work, will indicate the results in other cases; 10 per cent. solutions were used in each case:—

HCl	lost	2.88 %	Tartaric acid	lost	1.42 %
H ₂	"	1.0 %	Citric acid	"	Nil.
HNO ₃	"	2.5 %	CaCl ₂	"	3.1 %
HClO ₄	"	4.4 %	NaCl	"	2.77 %

We have here a purely physical reason for the concentration of substances in solution at surfaces. In some cases, from the opposite cause, there is a tendency for the substance to leave the surface.

The influence is proportional to the surface, and temperature has little effect on it, so that increased dyeing effect at higher temperatures is not to be traced to this cause. Salts, acids, &c., may therefore concentrate at the surfaces of fibres, or in their pores, and their action be intensified in this way.

This action should lead to abnormal concentrations in the case of pseudo-solutions, if the theory of solution strain is a correct one. This is so pronounced in the case of substances with very high molecular weight that these surface concentrations may be heaped up by mechanical means, and form visible films of solid or very viscous matter (Ramsden, Proc. Roy. Soc., 72, 156).

There is a distinct tendency for liquids to throw out of solution all substances in a state of high aggregation, the dissolving solution trying to resume its original volume. These concentrations occur also at the inter-surfaces of two solutions, and give rise to distinct surface tension phenomena at the junction of aqueous colloid solutions of different concentrations (Quincke, Drudes, Ann., 10, 478). "The explanation of these de-solutions must be sought in the reduction of surface tension, and therefore surface energy," says Ramsden. We may perhaps go further back, and refer it to the play between the secondary attraction of the solution mols., for those of the solute, the osmotic pressure effect, and the attraction of the solute mols. for each other.

The size of the aggregates undoubtedly alters the effect. Some experiments of Gore will confirm this. He found the surface results to vary as follows:—

Pieric acid in solution	No result.
do. in suspension	Result.
Salicylic acid in solution	No result.
do. in suspension	Result.
Methyl Orange	Result.
Orange G.	Result.

We have here perhaps an indication that salts which "salt out" dyes act by a preferential attraction for the solution molecules, being in a finer state of aggregation.

These mechanical surface aggregations with substances in pseudo-solution have been obtained with a diameter of 1/1,000,000.

These separated solids vary greatly in the nature of their resiliency. They are sometimes even brittle. The action of aggregation is non-reversible in these cases. They may be membranous, membranaceous, or fibrous, as the case may be, or they may even consist of particles lying side by side.

This special surface viscosity develops at very different rates in different solutions, and is accompanied in many cases by a resistance to "shear," showing that the coating is solid or highly viscous. Even a bubble of air passing up through such a solution will carry with it, and persistently hold, any particles in suspension.

In this action, coupled with the above laws of aggregation, we have a purely mechanical theory of dyeing which will satisfy the dyeing conditions in a great many cases, including the "one bath" method, indigo, and "sulphide" dyeing, "direct" colours, &c.

Some experiments of Chabrie (Comptes rend., 115, 77) roughly indicate the limits at which such action takes place in a capillary tube. If a solution of albumin (molecular weight, 10,000-15,000) be passed slowly through a capillary tube with an internal diameter of 0.007 mm., a separation takes place, and only pure water passes through. The albumin is concentrated in the tube, and ultimately prevents all flow. The molecules or aggregates of murex or Congo Red are not large enough to cause this action.

The molecular weight of the latter is only 826, against 10,000-15,000, but on the same lines a tube with an internal diameter of 0.0041 mm. might stop the flow in the same way. This stop in the flow will correspond with the point of saturation in any dyeing system, and we get an indication of the different actions of fibres also.

In addition to this action we have an indication in the arsenious sulphide experiments that there may be a secondary but active attraction between the dye particles and the fibre substance. In the case of basic dyes, decomposition may take place with the formation of very insoluble basic compounds.

It is known that molecular attraction increases enormously at very close quarters. This is said by Hawkesbee (Trans. Roy. Soc. XXVI. and XXVII., 1709 and 1713) to be the key to capillary attraction. This subject has been worked out mathematically by Laplace and Gauss.

This special attraction does not become sensible to our measurement at distances greater than 50 micro-millimeters. It becomes really sensible at 1 μ and becomes enormous before the molecules come into actual contact.

Assuming intensely dense molecules moving in space, the aggregation of which constitutes a mass, an intensification of Newton's law may explain this result. Some such secondary effect as this may have led to the belief that an action of the first order may take place between the fibre and the dye.

Action of Assistants.—The best experimental evidence we have of the action of these reagents on the fibres is perhaps contained in some work of Spiro (Science Abs., 1904, 922). According to this investigator, the swelling of colloids is accelerated by the presence of hydrogen or hydroxyl ions; in other words, in that of acids and alkalis. Such substances as dextrose, on the other hand, will retard the swelling. The maximum swelling with dextrose takes place, when gelatin is the colloid, with a 3 per cent. solution of dextrose. With a 25 per cent. solution no water is absorbed by the gelatin. With still more concentrated solutions the gelatin actually loses water and shrinks. It is therefore necessary that the fibre substance must be in a hydrated or "open" condition. This has been recognised for some time past.

Brown (J. Soc. Dyers and Col., 17, 92) has shown that there is generally speaking a critical point at somewhere about 80° C., and beyond this a decreased dyeing effect is produced.

This may be due either to the too perfect nature of the dye solution, or else to a dehydrating action on the fibre substance, similar in nature to that on aluminium hydroxide. When we consider the action of solutions on, say, silk or wool at temperatures above 100° C., the former reason is more likely to be the correct one.

If cotton is boiled for some hours with water an increased affinity for certain dyes is noticed (Hübner and Pope, this J., 1904, 404). The extra effect noticed with mercerised cotton is also probably due to this effect.

This action of temperatures on rate of dyeing (up to 80°) and the difficulty in dyeing fibres in solutions that do not "hydrate" them may probably be explained on these lines.

Even colloids, like egg albumin, are said to slowly pass through plates of gelatin; and recently de Mosenhuth (this J., 1904, 296) has shown that a 5 per cent. solution of nitrated cotton will dialyse on long standing.

Salts are said to increase the viscosity of gelatin (v. Schroeder, Zeit. Phys. Chem., 1903, 77). This indicates that the aggregates are increased.

Boiling colloids at 100° leads to a non-reversible hydrolytic action. The "tendering" of animal fibres in this way may be due to such an action. This action of hydroxyl compounds is even extended to colloidal ferric hydrate (Spiro), but the action is much weaker in the dialysate solution, showing the influence of the presence of a small quantity of an electrolyte.

The relative rate of diffusion of a substance in different states of pseudo-solution is unknown.

The rate of diffusion of crystalloids through a colloid like agar-agar is greatly increased by increase in temperature (Voigtlander, Zeit. Phys. Chem. 3, 316), as we see from the following table:—

Substance.	At 0°	At 20°	At 40°
Formic acid	0.47	0.86	1.4
Acetic acid	0.51	0.64	1.04
KOH	1.01	1.75	2.36
KCl	0.78	1.4	2.2

The generation of heat which accompanies the wetting of cotton must, apparently, not be ascribed to hydration. It has been long known that a rise in temperature takes place when finely divided solids are immersed in water or other inorganic or organic liquids (Pouillet, Ann. Chem. and Phys. 20, 230). Masson (Proc. Roy. Soc., 7, 230) considers that this is a distillation effect through layer of air. There is no definite limit to this effect, which sometimes goes on for hours, and gives an increased temperature of 8-12° in the case of cotton. Similar results were obtained with glass wool and water vapour. This investigator considers that if the solid is wetted no temperature effect is obtained, and that the action is not a chemical one.

Martinis' experiments (Phil. Mag. (5), 47, 329) do not seem to confirm these results. With pure silica he got a great increase in temperature with such substances, distilled water (22.6°), absolute alcohol (26°), sulphur ether (31.5°). Under exceptional circumstances the silica was raised from 17° to 80° C. All powders do not give this effect: calcium carbonate is an exception.

Martinis' explanation was that the liquids are absorbed by solids, and enter the solid state themselves (*Ibid.*, 50, 618). Later on he considered that the action was physico-chemical one. Silica will abstract water from mixture of three parts alcohol and one part water.

He notes that a reverse action is obtained in the case of mercury, which does not wet the solid. There clearly cannot be any chemical action here, or any distillation effect. The whole subject seems very involved in the present state of our knowledge. All the results do not seem to favour association rather than dissociation of the dyestuff.

+ —

If $\text{HCl} = \text{H} + \text{Cl}$ represents dissociation, association from the above point of view will be represented by

the secondary or residual attraction between the water molecules and the atomic constituents of the HCl weakening to a corresponding extent the primary attraction between the H and Cl.

This secondary attraction may be identical with molecular attraction, which at close quarters is known to

great, whatever relation it may bear to primary or secondary attraction. In the case of dissociation the positive and negative ions are said to be independent of one another; but if the molecular system be broken down in solution it must be by some force equivalent to, or greater than, the primary bond.

Great as we know molecular attraction to be, yet we have no evidence that it approaches in intensity the forces which hold the molecule together. The limited power which molecular attraction is of a sensible order is too small to preclude the idea that a smaller pull from an overwhelming number of solvent molecules might produce the effect.

At the same time such a state of affairs will explain how it is that we might have a "dissociation effect" in dilute solutions, and an "association effect" in strong ones.

From this point of view dissociation does not exist, but is a secondary phenomenon, and due to a weakening of the primary bonds by association with the solvent liquid.

The action is equivalent to a certain percentage of "ions" or inter groups being in the free state. If it is so, the forces which we know as molecular and atomic are unified, and brought within the range of the phenomena which, in their collected effect, we call gravity.

In the ease of actual decomposition, as in the case of electrolysis, I think there is evidence that the metal is present as a hydrate. Silk, for example, abstracts $\text{Sn}(\text{OH})_4$ from SnCl_4 solution, even when the latter is in a highly acid state (Heermann, *Färb.-Zeit.*, 15, 325 and 345), the composition of the absorbed substance being given as $\text{Sn}_{1.4} + 61.9\text{Sn}(\text{OH})_4$. Actual decomposition certainly takes place here. Mutual association seems to render this possible in the presence of a colloid, and this secondary attraction may induce chemical change, as indicated.

In conclusion, therefore, the conditions of dyeing would seem to be as follows:—

1. A solution state of dye, or mordant, within certain limits of aggregation.
2. State of fibre corresponding to this degree of aggregation.
3. Effective "localisation" of the dye, with subsequent concentration of the dye in the fibre substance.
4. De-solution, due to secondary attraction between fibre substance and dye, or "concentration" effect.
5. In rare cases, primary, or chemical attraction may play some part in the process at this stage.

There is no evidence in favour of solid solution in any of the above results, even in its recent and wider aspect. Molecular configuration still plays too large a part for the numerous actions in dyeing to be included under such a theory.

As it is seen, dyeing may take place on purely physical lines, and anyway, any chemical action would seem to be of a secondary nature and not essential to the process.

DISCUSSION.

Mr. W. H. PERKIN (senior) said he agreed with the author in thinking that in a large number of cases dyeing was not a chemical process. When he was first interested in his subject there was very little known about the theory of dyeing, but the idea occurred to him that if wool and silk could be obtained in the liquid state many dyes would be found very soluble in them. He tested this by first taking a solution of albumin, which was known to coagulate to absorb many dyes freely, and he found that by shaking it up with Murexide or rosaniline dyes dissolved them more easily than water. He then took naphthylamine (β -naphthylamine was not then known), and he found that crystals of this, if shaken up with these dyes, were quickly dyed, and also that the dyes were freely soluble in fused naphthylamine. He also obtained a similar result with phenylacetamide. Like others who had since worked on the subject, his idea was that dyeing in many cases was due to what had been called "solid solution." No doubt in some instances there was a chemical combination, for example, with mordants such as tannin and tin on cotton, because

one could get a compound of colouring matter, tannin and tin without cotton, and there were other cases, in which no doubt it was chemical, but where the pure dye and the pure fibre was used, when it was very questionable whether chemical action had anything to do with it. He remembered making some experiments on the surface character of cotton, wool and silk, and being very much struck with the difference between them. He worked a quantity of cotton for some time in an emulsion of olive oil and carbonate of potash, such as Turkey-red dyes used, and rinsed it well in clean water; on wringing it out afterwards, nothing but pure water ran from it, the cotton being practically free from oil. He then did the same with silk, and the water was nearly pure, but the silk was quite moist with oil. He did the same with wool, and after rinsing that out in clean water and then wringing, the oil ran from the wool in quantity. He did not know that that had much connection with the dyeing character of those materials, but, speaking generally, the behaviour of these different fibres in relation to the oil corresponded closely to their dyeing power.

Mr. R. J. FRISWELL said that the author had very carefully studied the ground-work of what was an extremely complex subject. There was no doubt that the chemical explanations commonly given were no explanation of dyeing phenomena, and he felt very much inclined to say that the true explanation would not be arrived at even on the theory of solid solution or of osmotic action, because the whole subject was so exceedingly complex, and in so many cases there was interference of one of these actions with another. Take for instance the case of a dye like the lower sulphonic acids of phenylated rosanilines; these bodies were extremely soluble in sodium carbonate; to dye wool with them it would follow that the percentage of sodium carbonate in solution should be reduced as far as possible to get the best dyeing effect. But if instead of beauty of shade, depth or concentration was the test, the contrary was the truth. The greater the amount of sodium carbonate present, the greater was the dyeing effect on the wool. He had carried that on until he had reduced the wool to a state in which it was perfectly rotten, almost beginning to dissolve, simply by increasing the amount of sodium carbonate. There were other cases such as the dyeing of resins, in which there seemed to be a definite chemical combination between the dyeing substance and the resin. The same was true with regard to certain soaps, some of the most beautiful effects in dyeing cotton when the soluble blues—the sulphonated the triphenylrosaniline compounds were not used—were obtained by dyeing in water from very dilute alcoholic solutions of the basic blues on alumina soaps, which were obtained by first treating the cotton with Castile soap and then with acetate of alumina. Again, they had the extraordinary fact that bodies like precipitated ignited silica could be dyed with a great number of dyes both basic and acid in character, and the fact that the dyeing solutions themselves would even dye silicates, glass and porcelain. Then they came at last to a fact which had not been mentioned that evening—the action of light. If some of these dyes, especially those which possessed the power of dyeing bodies like glass and silicates, were exposed to light in a bottle, the side of the bottle which was exposed would be dyed to an enormously greater extent than the side away from it; in fact, the whole question was extremely complex. He hoped this was merely a preliminary to a series of experimental papers on dyeing from the author, which would place their knowledge on a much sounder footing than it was at present.

Mr. F. EVERSHED said that Mr. Dreaper had referred to a number of experimental results, some of which were extremely interesting and apparently novel. For example, it was stated that alcohol containing 5 per cent. of water would remove certain dyes from fibres but not others: what dyes were referred to, and what were the conditions of the experiments? Then Mr. Dreaper had said that naphthylamine could be fixed on wool and cotton from a solution in alcohol and water, and that the fibre would take up from 5 to

30 per cent. of the amine. That was very extraordinary, and the details of those experiments would be interesting. He asked for particulars of the action of certain salts in increasing the affinity of indigo for cotton, and a description of the very remarkable experiment in which indigo, although not in solution, exerted osmotic pressure. Surely it was a new and startling fact, if true, that a substance not in solution could exert osmotic pressure.

Then, again, the action of boiling water on cotton was said to increase its affinity for certain dyes. To what extent was the affinity increased, what were the dyes in question, and what ground was there for supposing that the increased affinity of mercerised cotton for dye-stuffs was due to the same kind of action? That did seem rather illogical, for cotton was not heated in the mercerising process, and in the other case no alkali was used, so that the likeness between the two processes was not obvious. It struck him that Mr. Dreaper had expended a great deal of speculative ingenuity in endeavouring to arrive at a new theory of dyeing, but the connection between theory and fact did not come out very clearly in his discourse.

Mr. C. F. Cross said Mr. Dreaper had a very difficult task in endeavouring to generalise these phenomena of dyeing, which rested on the borderland of molecular physics, but the use of mere terms, such as "mechanical," "physical," or "chemical" was really quite beside the mark.

He had been in correspondence with a school of German chemists who were working on the whole subject of colloids, and he would not pretend to go into such a range of research as their literature covered, but they all agreed that at the moment they were entitled to assume that cellulose was a solution in an important sense of the term; so far in effect that we could apply to cellulose the modern ideas of solution; that cellulose did not contain preformed dextrose molecules in any sense, but was an aggregate of ions which took their origin under the special conditions obtaining in the plant cells of which celluloses were mass aggregates; that it was necessarily a mixture of ions of varying dimensions, and, as a consequence of this, cellulose, as a typical colloid, had no definite reacting unit such as is assigned to a body which takes the crystalline state nor a fixed molecular constitution, such as could be represented by a constitutional formula. It was a body which had reacting dimensions according to the number of ionic exchanges which took place in the particular sphere of reaction under consideration. That is to say, it was not a static unit which could be measured in terms of the ordinary physical measurements, but represented rather a dynamic equilibrium and the reacting unit of cellulose at any particular moment was simply a function of the conditions in which it was placed. He would not go into this at any length now, as they were preparing a brochure on the subject. He was sure that Mr. Dreaper, with whom he had discussed these phenomena before, would agree with him that the use of terms at the moment was perhaps a little unnecessary. They all required to suspend their judgment and to really inquire into the hypothesis which he had endeavoured to formulate in those few words; that the fibre-colloids react in all essential respects as solution aggregates and not as polymerised molecules or fixed units. That would in itself explain many of the phenomena of dyeing, and in his opinion if that view of colloids were prosecuted to the end, and especially taking into account these very typical dyeing phenomena, it would be found to explain very much that at present appeared to be extremely nebulous.

Mr. W. P. DREAPER, in reply, said with regard to Dr. Perkin's remarks, he thought himself that the great evidence against the chemical theory was, that if the silk fibre were regarded as an amido acid, and the necessary steps were taken to "deamidate" the fibre and remove the NH_2 or NH groups, it was found that the silk dyed with acid colours just as well as before. It seemed to him that that fact, which seemed fairly well established, was absolutely fatal to any theory of an amido acid nature. With reference to the experiments with the sulphonic acids mentioned by Mr. Friswell in the presence of sodium car-

bonate, he did not think the idea that they acted again the theory of aggregates was correct. The action of sodium carbonate there was more an action on the fibre itself, and was probably a hydrating one, especially if it happened to be wool. This was of importance and overbalanced any action of reduced aggregation on the dye-stuff in the alkaline solution. With regard to the action of dyes on recently-ignited silica, it might be due to surface concentration; if the silica was not actually washed, and some of the solution merely withdrawn in a pipette, this might be mistaken for an attraction of the silica itself. It might only be due to surface concentration on the powdered silica. Otherwise, he thought the surface of the silica in the presence of water was always slightly hydrated, or in a colloid state, and the dye was attracted by that portion of the silica. As regards the osmotic pressure on the indigo, the fact was noticed by Linder himself, and it was undoubtedly a fact that pseudo-solutions, or colloid solutions did actually give rise to osmotic phenomena. In the case of arsenious sulphide a pressure equal to, though, 17 mm. was obtained. He referred to the action of mercerised cotton being similar to that of boiled cotton because he thought it would be generally recognised that in the case of boiled cotton a hydrated product was obtained. The alkali in the case of mercerised cotton was, of course, not essential to the finished product. A similar effect was obtained in both cases. The experiments in that case were some published recently in this Journal in one of Hübner and Pope's papers. As regards Mr. Cross's remarks, he perfectly agreed with him that it was very difficult, in the present state of knowledge, to define too closely theoretical considerations, but at the same time, if they altogether overlooked the side of the subject, they might miss their opportunity. He thought that it was better to consider the two sides together, rather than wait until the experimental data were complete before theoretical considerations were taken into account.

DR. J. T. DUNN IN THE CHAIR.

METHODS FOR SEPARATING AND DETECTING MIXING ZINC IN BLENDES AND OTHER NATURAL AND ARTIFICIAL PRODUCTS.

BY THE LATE H. SALVIN PATTINSON, PH.D., F.I.C., AND GEORGE C. REDPATH.

The separation of zinc from metals associated with it in blenders, flue-dusts, &c., frequently gives trouble, and discrepancies occur when the same sample is analysed by different analysts. These discrepancies are probably due, in most instances, to imperfect separation rather than to errors in the zinc-determination itself.

We have obtained satisfactory results from the methods of treatment, and, though this record of our work contains nothing new in principle, we think our figures and results may be useful to those who, like ourselves, have very frequently to assay, for zinc, ores and artificial products which contain it.

1. *Von Schulz and Low's Method.*—In this method the ore is dissolved in nitric acid and potassium chlorate evaporated to dryness, the residue heated, cooled, and extracted with ammonium chloride and ammonia. The zinc in the solution so obtained is titrated with ferrocyanide, using uranium acetate as an indicator, and ferrocyanide is standardised by means of a solution of

ing a known amount of zinc, to which has been added out as much ammonium chloride as the actual solutions assay contain. The method is described in this Journal, 1892, 846, so that details need not here be given. Modifications we have found necessary or desirable accurate work are as follows:—*a.* In dissolving the ore, use hydrochloric acid alone in the first place, and after the time add nitric acid. *b.* We find it necessary after reacting with ammonium chloride and ammonia, to re-evaporate the residue in hydrochloric acid, evaporate to dryness, and extract a second time. This being so, we use for each extraction a smaller amount of ammonium chloride than *v. Schulz* and *Low* recommend—1 gram. of ammonium chloride and 3–5 c.c. of ammonia, instead of 5 grms. of ammonium chloride and 15 c.c. of ammonia, for each gramme of ore. As the figures in Table I show, we usually leave, working thus, a little more zinc for a second extraction than if we used the larger amount of ammonium chloride in the first place; but the second extraction is in all cases necessary, and is in either case complete. *c.* We find it desirable to wash with 5 per cent. acid of 1 per cent. ammonium chloride solution. *d.* If manganese be present with the zinc, we precipitate it by adding bromine to the ammoniacal solution, filter, redissolve the precipitate in hydrochloric acid, add ammonium acetate, precipitate by hydrogen sulphide any zinc not precipitated down with the manganese, dissolve the zinc sulphide in hydrochloric acid, and add it to the main solution.

We have added to Table I some figures for a known mixture of zinc and iron salts, which show that the ammonium chloride rather than the ammonia is the active agent in the extraction. We have also found that the residue from evaporating to dryness a solution of zinc chloride containing 0.5 gram. of zinc may be heated for an hour to 470° C. without any loss of zinc; if the solution contains, in addition to the zinc, 1 gram. of ammonium chloride, an hour's heating of the residue at 470° C. volatilises 0.006 gram. of zinc, but no zinc is lost after an hour's heating at 200° C.

ore and neutralisation of the solution are carried out exactly as in *von Berg's* method (either ammonium or sodium carbonate may be used in the neutralisation); then 1 gram. of gallic acid as ammonium salt and 2 c.c. of the free acid are added, and the zinc is precipitated as directed by *Lewis*. The further treatment of the zinc sulphide and the examination for impurities are carried out exactly as described under *von Berg's* method.

A few typical figures obtained in actual practice are given in Table II. It will be seen that the three methods

give very closely agreeing results. On the whole, for rapidity and convenience, we prefer to use *von Schulz* and *Low's* method, though the others are also fairly quick and not at all tedious. Of the two sulphide methods, *von Berg's* is distinctly to be preferred on account of the greater density of the sulphide precipitate, which allows of its being collected on a smaller filter and being more rapidly washed than is the case in *Lewis's* method; moreover, cobalt, if present, interferes with the accuracy of

Von Berg's Method; see *Dittmar*, *Quantitative Analysis* (1887), page 104.—1 gram. of the ore is dissolved in hydrochloric and nitric acids, evaporated to dryness in sulphuric acid, taken up with dilute sulphuric acid, filtered, the residue on the filter being well washed with dilute sulphuric acid. The filtrate is nearly neutralised with ammonia, then ammonium carbonate is added till a permanent precipitate appears. This is just dissolved in sulphuric acid, ammonium chloracetate or chloracetic acid added, and the zinc precipitated with hydrogen sulphide according to *Dittmar's* directions. The washed sulphide may be treated in a variety of ways:—usually dissolve it in hydrochloric acid and bromine, precipitate by sodium carbonate, and weigh the zinc as oxide. Any small amounts of co-precipitated iron, manganese, or copper are determined, and subtracted from the weight of the oxide so obtained.

Lewis's Method: *Analyst*, 28, 93.—The solution of the

Lewis's method, but is completely separated from the zinc by *von Berg's* method.

Von Schulz and *Low's* method can be very advantageously used for the separation of zinc in the course of analysis of iron ores, &c., being more rapid than the acetate method. In no case have we found any zinc remaining in the residue after two extractions with ammonium chloride and ammonia.

In the course of our work we also examined a very ingenious method of separating iron from zinc and other metals, devised by *Nicolardot* (this J., 1901, 1242), depending on the precipitation of the iron as basic sulphate after a molecular change produced in the chloride by long heating to 125° C. Though this frequently gave a very complete precipitation of the iron, however, it did not always do so; and as the other methods we have described proved so satisfactory, we did not investigate the method further.

DISCUSSION.

Mr. W. W. PROCTOR said that while the volumetric method was suitable where many estimations of zinc were required in a short time, he preferred to use a gravimetric process where accuracy rather than time was the object. Time and trouble were required to obtain a solution free from interfering metals such as lead, copper, iron and manganese, and having obtained such a solution, if some modification were made in the process usually recommended, the additional time required seemed to be compensated by the greater accuracy of the result obtained by actually weighing the oxide of zinc obtained in the analysis. He would advise bringing the ammoniated solution, freed from interfering metals, nearly to boiling, precipitating the zinc with a slight excess of ammonium sulphide, and boiling for about 15 minutes, by which means the slimy precipitate of zinc sulphide became granular and subsided more readily, so that it could be washed by decantation; a few drops of ammonium sulphide and chloride were added to each wash water and the mixture again boiled, and allowed to settle. The precipitate did not then require much washing. The filtrate was usually clear, but if turbid it should be again warmed up with a little ammonium sulphide and chloride, if necessary, and passed through a separate Swedish filter. The precipitate should then be dried gently with the filter in a platinum crucible, so as to char the paper, which was then burnt off at a temperature too low to reduce the zinc. Zinc sulphide was not so readily reduced as the oxide. The process might, of course, be assisted by moistening the char with a little ammonium nitrate solution. On now heating the residue more strongly, with free access of air, the sulphide was almost entirely converted into oxide, if the amount of zinc was not much more than 0.5 gm. It was then weighed, but as it usually retained a small amount of sulphuric anhydride, it was dissolved in dilute hydrochloric acid, boiled, and precipitated with barium chloride in the usual way. This need not require more than a quarter of an hour, as the barium sulphate was only in small quantity and easily filtered off. The precipitate of barium sulphate was calculated into SO_3 , and this, when deducted from the mixed zinc oxide and sulphate, gave the amount of zinc oxide from which the quantity of zinc existing in the ore was easily found.

By acting in this way the tedious operation of converting into carbonate was avoided, as well as the unpleasant action of sodium carbonate, if glass or porcelain vessels were employed, which rendered it necessary to examine the precipitate for silica.

Mr. ERNEST JACKSON said that the method he had used for extracting the zinc previous to titrating with ferrocyanide differed from that employed by the authors. It was carried out in the following manner:—The blende, or flue dust, was dissolved in nitro-hydrochloric acid, evaporated to dryness and the silicious matter, &c., separated. The solution was then carefully neutralised with ammonia, slightly acidified with hydrochloric acid, and any lead, copper, cadmium, &c., precipitated. (In the case of a large percentage of copper being present, the precipitate was re-dissolved and examined for zinc.) After filtration the solution was boiled to expel hydrogen sulphide, oxidised with nitric acid, and, after the addition of bromine, poured into an excess of ammonia. The precipitate of iron, manganese, alumina, was then filtered off, re-dissolved in hydrochloric acid, and re-precipitated in the same way, the filtrate being added to the main solution. If a large quantity of iron, alumina, or manganese were present it was advisable to re-precipitate again and examine the filtrate for zinc by the addition of ammonium sulphide. The solution was boiled to liberate most of the ammonia, carefully neutralised with HCl, 6 c.c. HCl added in excess, heated to above 75°C , and titrated with ferrocyanide. The indicator used was a 4 per cent. solution of uranium nitrate, this having been found to be more reliable, in the presence of hydrochloric acid, than the acetate solution.

When the copper and cadmium were present in small quantities, the solution, after separating the silicious residue, might be treated as above for the separation of

iron, &c., and after neutralising with excess of ammonium 6 c.c. HCl added in excess and saturated with hydrogen sulphide. On heating to the same temperature as before the solution was ready for titration. It was most important to regulate the degree of acidity since the interfering metals—cadmium and copper—were to be precipitated, whilst it was inadvisable and unnecessary to precipitate the lead sulphide. The presence of sufficient acid was necessary to prevent the precipitation of the lead but if the solution be too acid, the cadmium would be thrown down. It was found by experiment that 6 c.c. excess of hydrochloric acid in the final bulk of 200 c.c. solution gave the most accurate results. Tests carried out by the gallic acid method referred to by the author gave results concordant with those obtained by the method described. This means of separating the elements interfering with the accurate titration of zinc by ferrocyanide, although probably not so rapid as the process described by the authors, left nothing to be desired with regard to the accuracy of the results obtained.

DR. RUSSELL W. MOORE IN THE CHAIR.

IMPROVED METHODS OF APPLYING RADIUM

BY HUGO LIEBER.

The proportions of the radiations given off by radium and its disintegrated emanations are about 95 per cent. of α -rays and about 5 per cent. of combined β - and γ -rays. Because of their nearly negative penetrative power the α -rays, as well as the emanations, are practically unavailable for therapeutic purposes when the radium is used in glass tubes or similar containers. Even the superficial layers of a given radium preparation are relatively impervious to both the emanations and the α -rays proceeding from the underlying portions of the preparation. Therefore it is essential, in order to obtain the radioactive effects of a given quantity of radium, to have the radium in such a form (1) that the surrounding walls of the container could intercept neither the α -rays nor the emanations, and (2) that the given quantity of radium should be spread out so thinly that, practically speaking, an upper layer would not exist. These requirements finally led to the production of what the authors term "radium coatings."

Radium coatings are made in the following manner: Radium is dissolved in a suitable solvent and into this solution a suitable material is dipped. This material is then withdrawn, with radium solution adhering to it, the solvent quickly evaporates, leaving the material covered with an exceedingly thin film of radium. The kind of solvent to be used is determined by the nature of the material to be coated. Such solvents are employed which have a tendency to soften and to permeate the material which is to be coated. Thus, if celluloid rods, discs, or similar instruments are to receive a radium coating in order to be used for therapeutic purposes, solvents such as alcohol, amyl acetate, &c., may be employed. These solvents have a tendency to soften celluloid temporarily. When the solvent evaporates, the radium has been uniformly distributed over the celluloid, and has also been incorporated in its surface. In order to prevent accidental removal of the radium in such coatings, the celluloid instruments produced in this way are dipped for a short time in a collodion solution. By this process the whole radium coating is covered with a very thin film of collodion. In the course of a few days this film of collodion becomes so tough that it will strongly resist destruction, thus affording ample protection for the underlying radium. This thin film, however, permits the α -rays as well as the emanations to penetrate freely.

In the preparation of these coatings both the radium and the collodion solutions are coloured with an aniline

This is done to show the part that has been coated, les, if the radium happens to be removed by accident herwise, as by scraping, &c., the disappearance of the r makes such removal evident.

The great difference between radium used in containers, osed even of exceedingly thin aluminium, and um used in the form of the coatings here described, own by their relative influences on the electroscopes; heate rod coated at its tip with radium bromide of 10 activity and holding, therefore, very little radium, oared very favourably in its effects with 1 grm. of im bromide of 10,000 activity in a glass tube, or with 1 grms. of radium bromide of 1,000,000 activity in a thin aluminium tube.

The scintillations produced upon a zinc sulphide screen overed radium, such as is shown in the spintharion of Crookes, are produced solely by the impact of the rays upon the zinc sulphide. If what has been d above is correct, that is, that the α -rays can ntrate the collodion coating of the celluloid rods, discs, then the latter should yield evidence of these scintilla- when placed upon a zinc sulphide screen. Such illations were abundantly demonstrated with various os of the coatings.

Radium emanations will always follow an air current. xsequently, if some uncovered radium is placed in an urrent, the current will carry with itself the eman- ion, which emanations will ionise the air and discharge he electroscopes.

The radium coatings make it possible to apply radium ly to practically any part of the body. The radium applied would be practically equivalent in radio- e effects to the same amount of uncovered radium e same thin layer. Any instrument could be con- ntly coated with radium at a proper place, by the od indicated, and the radiations could be brought action wherever desired.

The great advantage of these radium coatings is that all uments, &c., coated by the method described, can be ly sterilised without loss of radium, for the protective e effectively resists even continued boiling. A strip of oid which had been coated with radium and then collodion, was placed in water in a test tube, and the nts vigorously boiled: both the radium and the col- n solutions used for the preparation of the coatings een coloured with a soluble blue aniline dye. That he collodion protected the radium was shown by the fact he water, after boiling, was entirely free from colour. he strip also retained its original radioactivity.

PROF. H. R. PROCTER IN THE CHAIR.

THE MICROSCOPICAL EXAMINATION OF SUMACH ADULTERANTS.

(Communication from the Leather Industries Laboratory of the University of Leeds.)

BY HOWARD PRIESTMAN.

In making microscopical investigation of sumach for adulterants, several difficulties occur which are worthy of

mention before making a comparison of the various cuticles with a view to identification.

In the first place, the thickness of the leaves and the nature of their constitution makes it impossible to see through them until they have been treated with some reagent which will separate the cuticles from the substance of the leaf, so that only the stratum of single cells, which forms the cuticle, will remain. Hot concentrated nitric acid is most generally used for this purpose, although this treatment, if prolonged to boiling, will entirely destroy the tissues of *Rhus Coriaria* and most other leaves.

This fact makes it very difficult to form any idea of the percentage of foreign matter in any mixture, because so much of the leaf substance in *Rhus Coriaria* will be destroyed before the cuticles of stronger leaves are separated. Workers in this branch of research will soon find other minor difficulties which need the greatest care if comparisons made under the microscope alone are to be of any use. The different cuticles vary very greatly in thickness, the lower cuticles of *Rhus Coriaria*, *Cotinus* and *Glabra* being so thin and transparent that it is difficult to see their structure until they are dyed; and the writer found it equally difficult to dye them uniformly and to free them from wrinkles under a cover glass.

In order to get sharp negatives of considerable enlargement, it seems necessary to have the slide coloured to some non-actinic shade, so that the actinic and visual foci may be the same, and the image formed upon an isochromatic plate may be perfectly sharp. For this purpose safranin and acid red seem equally suitable, the former being simpler to use because most of the cuticles take it quickly and retain it uniformly after they have been dehydrated with alcohol and benzene, and mounted in balsam. Even these dyes did not prove as good as could be wished for the three very thin cuticles already mentioned, and no satisfactory photographic results were obtained until dehydrating was given up and glycerine jelly used as a mountant instead of Canada balsam. This, of course, gives much less permanent slides than balsam, but if well ringed with asphalt black, slides mounted in jelly will doubtless last for a considerable time.

In the case of *Colpoos Compressa*, *Rhus Metopium*, *Pistacia Lentiscus*, and the upper cuticle of *Rhus Glabra*, dyeing is really unnecessary, because the cuticles are dense enough and yellow enough to give a very definite image, showing the cell walls quite plainly if they be mounted just as they come from the neutralising bath after being treated with nitric acid.

Genuine sumach, consisting of the leaves of *Rhus Coriaria*, is very easy to distinguish from all other vegetable products used as adulterants, because both upper and lower cuticles are covered with a dense growth of hairs. Those on the upper surface are about 0.005 inches long, tapering all the way from the root to the point; the root itself being bulbous, so that each hair strongly resembles a badly made hob nail, both in size and shape, when seen under an enlargement of 120 diameters. The upper cuticle is much stronger than the lower one, and when it is entirely separated from the vein structure it shows a well-defined cell structure, so arranged that the base of each hair forms the centre of a symmetrical group of 10 or 11, 4, 5 or 6 sided cells, so that when the hair is absent or quite transparent, the root space appears like a large stomata very clearly defined (figs. 2 and 1).

Stomata proper seldom if ever occur on the upper cuticle. The lower cuticle is very thin and transparent and is so difficult to handle that large portions are seldom obtained, but like the upper cuticle it is thickly covered with hairs, which, in this case, are thinner and longer, varying from 0.015 to 0.03 in length. Owing to its extreme thinness and transparency, the lower cuticle seldom absorbs sufficient dye to affect its colour after it has been treated with alcohol and benzene, whilst the lower hairs have sufficient substance to absorb a great deal of colour, consequently appearing very dense to transmitted light. For this reason they form a very prominent feature in photographs. In spite of the extreme transparency of the cuticle, careful inspection will reveal a large number of stomata between the roots of these longer hairs, and in addition there are always present some very small club-

curious waviness in the well-defined walls, which makes it easy to distinguish (fig. 13).

The upper cuticle has no stomata, and the cells covering the veins are elongated and distorted in a marked manner. The lower cuticle also shows very frequent vein markings between them there occur numerous stomata, each forming the centre of a group of less defined cells, which are surrounded by others with stronger walls. Stomata do not occur on the vein markings (fig. 14).

Rhus glabra is an exception to the general rule that such adulterants are quickly soluble in boiling nitric acid. Although the lower cuticle is so thin as to be visible to the naked eye, and very difficult to see under the microscope, the upper one is extremely strong, and the effects of boiling nitric acid for quite a long time. It has a well defined cell structure without stomata with frequent vein marks (fig. 21).

The lower cuticle is very difficult indeed to dye and, on account of its extremely thin and transparent nature, but as it carries small club-shaped hairs and shows minute stomata, it is the most important exception to the general rule and worthy of notice on this account. Extreme transparency makes it very difficult to photograph, and no regular cellular structure is visible. When it has been dehydrated in alcohol and benzene and mounted in balsam, it was found quite impossible to get any result whatever with the camera; but it was found, as in many other cases of difficulty, that fairly good negatives could be obtained if the same specimens were mounted on slides in glycerine jelly (fig. 22).

Limonium complanatum separates easily in nitric acid, the two cuticles being of nearly equal strength and density; they are easily handled and may be observed and photographed after neutralisation, but without dye.

Neither cuticle carries fibre of any kind, but both have stomata, and they only differ from one another in the nature of the cell walls, which are less defined in the lower than in the upper cuticle, though they are of similar form in both (figs. 15 and 16).

Rhus glandulosa like *Rhus glabra* separates easily, and has a very thin lower cuticle, but is not entirely soluble in boiling nitric acid; unlike *Rhus glabra* it has no stomata of any kind upon it, and both cuticles show a distinct cell structure (figs. 19 and 20).

The upper cuticle the cells have well defined walls of approximately the same size as those in other leaves for the same purpose, but there are no stomata, and the cells which cover the veins are elongated and distorted to such an extent that they show very distinctly.

The lower cuticle has similar characteristics but the stomata are frequent, and as is often the case with other adulterants, the shape of the cell walls is less definite, the vein markings being so dark as to be very noticeable.

Tamarix africana differs from all the other adulterants in that the commercial article is composed entirely of stem twigs instead of leaves. If, however, it is subjected to the same influences as the leaf adulterants of sumach, it undergoes even more striking disintegration, for although the stems are so much harder than the leaf tissue, they are easily soluble in hot acid, and if a sample in nitric acid is used slowly in the water bath at about 70°, it will be seen that the cuticle begins to separate from the stem proper, and at 80°—85° it will be floating loose in the acid. If it is desired to dissolve the stem fibres entirely, the density and size make it necessary to keep the test tube at this temperature for 5 or 10 minutes, and as the cuticle itself is soluble at a little over 90°, it is well to maintain a temperature not over 75°, for a longer period than to dissolve the core fibres quickly by raising the acid to a point at which the cuticle also will begin to dissolve (figs. 7 and 8).

These facts are equally true of the stems of *Rhus glabra*; the stem cores of that plant dissolving at 75°—80°, whilst the delicate transparent stem cuticle with its fine growth of hairs and frequent stomata or holes, remains undissolved at 95°.

The cuticle of *Tamarix* has a well defined cell structure; the cells being elongated in the direction of growth, and not infrequent stomata arranged between pairs of primary cells. For some reason it is never easy to

straighten this cuticle on a slide; it is always apt to double on itself and to lie in creases, which give an incorrect impression, and as already noticed, it has been raised to a temperature near to the point at which it dissolves, it tends to consolidate into gelatinous lumps, which are naturally of no use for investigation. As it carries no hairs of any kind on its surface it is easy to distinguish from *Coriaria stem*, where fibres are always to be found, and even if this distinction were wanting, there should be no difficulty in deciding between the different cuticles simply from the nature of their cell structure (fig. 8).

Rhus Cotinus.—With the exception of vine cuticle, that of *Rhus Cotinus* is the most transparent of the cuticles of this group. Both upper and lower cuticles are so clear that they show little or no cell structure even when dyed, for they absorb so little dye that the transparency is very slightly impaired, but the club-shaped hairs which take a small percentage of the dye are more easily visible on the upper cuticle after dyeing (figs. 17 and 18).

The cuticles are so difficult to handle, or even to see when in the acid, that it is almost impossible after boiling them to say which is upper and which lower. There is no definite indication of stomata in either of them.

Vitis vinifera (English vine) requires slower treatment with nitric acid to separate the cuticles. If the temperature of the water bath were raised at such a speed as to boil in 10 minutes, the leaf substance will not dissolve until 80° is reached, and as the cuticles begin to disintegrate at 85°—90°, they are always very soft and difficult to handle if they are separated in this way. On the other hand, if the bath be warmed so slowly that 20 to 25 minutes are required to raise it to 60°, the cuticles will be found to separate easily, with much less tendency to tear. They will also be found stronger if only just sufficient alkali is used to neutralise the acid, so that they are not treated with a superfluity of strong alkali.

The cuticles are both extraordinarily transparent; the upper one only showing indistinct cell structure with no stomata, or hairs of any kind, whilst there are very large numbers of the stomata on the lower cuticle and something resembling short straight pointed fibres, say 0.005 in. in length, has at times been seen on isolated samples.

The structure of the veins is very curious. On the under side of the leaf they seem to consist of ribs, covered with a kind of fibre, adhering so loosely that it may spread over adjacent portions of the leaf, giving the whole surface the appearance of being covered by a dense growth of fine fibres, although this is not really the case.

A sample of ground Italian vine leaves, such as are actually used for adulteration, give results very similar in every way to English leaves. It is difficult to dissolve all the leaf substance without softening the cuticle because the nitric acid sets up such violent action as to raise the temperature without the aid of a water bath at all.

The rare samples which can be found free from leaf substance are absolutely transparent and difficult to dye. If mounted in balsam or other benzine solution they give no result in the camera, and the best results have been obtained from temporary slides mounted in water. In this condition also the cuticle is transparent, but the difference in thickness between the walls and other portions of the cells causes refraction which is more apparent with wide angle lenses; the photographs being taken by this method with a very small condenser stop and a Zeiss B. objective giving about 120 enlargements (figs. 23 and 24).

Cercocarpus, carob tree or leucostemum (*Cercocarpus Siliqua*) resembles *Pistacia lentiscus* in many ways. The cells are similar in arrangement and size, but appear to have somewhat thicker walls. Both cuticles are strong, the lower one containing stomata, but specimens appear very seldom after boiling, and it is probable that much of the lower cuticle is without stomata.

Neutralisation with ammonia leaves the cuticle of a definite yellow colour, and there is no need to dye it prior to photographing (fig. 9).

Unless there is some chemical colour test which will differentiate between these leaves and those of *Pistacia lentiscus*, it would be impossible to swear that a given sample contains either one or the other for certain.

Arbutus, *Arbutus undedo*, is a plant of the heath tribe,

more nearly resembling *Tamarix africana* than any other specimen hitherto examined. Samples submitted contain a great deal of stem substance soluble only at about 100° in 20 minutes, the cuticle of which is so like *Tamarix* cuticle in the arrangement of the cells and the stomata, that great care must always be necessary when dealing with either of these adulterants, for it is the writer's opinion that the microscope alone can never tell for certain which is which (fig. 12, taken with 1 in. lens).

NOTE.—All the photographs used as illustrations on this paper were taken with a Zeiss E. lens.

DISCUSSION.

Prof. H. R. PROCTER mentioned *Rhus coccinea* and *Rhus copallina* as American sumachs, used in the United States for tanning purposes. Tumerisk was collected in Africa and used for adulteration. It was impossible to detect dried exhausted sumach microscopically, but this was of small consequence if sufficient tannin were present. Pistacio had been tried as a sumach substitute, and in some cases was a useful material, but the tannin was different in character from that of the true sumach. Some other adulterants spoiled the colour of leather. *Cedropom compressum* was not an adulterant, but a sumach substitute, and in many respects resembled pistacio. It was used in South Africa, especially in Cape Town.

Mr. F. W. BRANSON asked if nitric acid of slightly lower specific gravity had been used where the stronger acid destroyed the cuticle.

Mr. G. W. SLATTER asked if siliceous matter, absorbed by the plant from the soil was the cause of the resistance of the cuticle to nitric acid, or if this could be attributed to something else. Perhaps the shape of cells, which he thought were different in some of the specimens, might be a useful means of identification.

Dr. SMITH said the cuticle might be chemically a more indefinite substance than starch or dextrin. Resistance must be due to the cellulose wall becoming impregnated and converted into cutine. Cutine remarkable in giving no tests. He asked why many substances could not be identified with low powers in seed testing. If small tests were made, could impurities be thrown out and analysed? With reference to whole *Rhus*, which were covered with hairs, some might be detected by the low powers of the microscope, but would perhaps require treatment.

Mr. HOWARD PRIESTMAN said *Rhus coriaria* contained abundance of hairs. No other plant had hairs at all. The cell structure of the cuticle was the only visible when undyed. After practice, the upper cuticle of *coriaria* was easily detected, though several adulterants were difficult to identify with certainty. The apparatus used for taking the micro-photographs consisted of a simple box camera and taper bellows. Light was supplied from an ordinary incandescence burner passed through a bull's eye and sub-stage condenser. The initial difficulty was in getting good definition especially with ordinary plates. If red dye and chromatic plates were used the focus was easily obtained.

Prof. H. R. PROCTER explained that the ordinary nitric acid of sp. gr. 1.42 was used. Siliceous matter was a possible cause of the resistance of the cuticle to nitric acid, but other substances such as waxy matter contained in many plants of the evergreen class, tended to similar results. The shape of stomata and special arrangement of the latter had been noticed in the work. Samples when received in this country usually very finely ground, and this prevented the use of low power objectives for separating the various constituents.

PATENT SPECIFICATIONS may be obtained by post by remitting as follows:—

English.—5s. each, to the Comptroller of the Patent Office, C. N. Dalton, Esq., Southampton Buildings, Chancery Lane, London.

United States.—1s. each, to the Secretary of the Society.

French.—1 fr. 25 c. each, to Belin et Cie., 56, Rue des Francs-Bourgeois, Paris (3°).

I.—PLANT, APPARATUS, MACHINERY.

ENGLISH PATENT.

Condensing and Cooling Apparatus. H. Austin, Formby, and G. Scott and Son (London), Ltd. Eng. Pat. 7139, March 24, 1904.

THE inventors claim a combination of apparatus in which the vapour from an evaporator is first condensed in a tubular or other form of surface condenser, the condensed liquid being subsequently cooled in a series of counter-current, tubular cooling vessels. These are so arranged that the cooled liquid only leaves the coolers as it is dis-

placed by freshly-condensed liquid from the condenser. By this arrangement the entire surface of the cooling and condensing devices is utilised. Claim is also made for causing the cooling medium to flow in the opposite direction to that taken by the vapour to be condensed, and the condensed liquid formed.—W. H. C.

UNITED STATES PATENTS.

Filter. K. Kiefer, Cincinnati. U.S. Pats. 781,830 and 782,200, Feb. 7, 1905.

SEE Fr. Pat. 344,254 of 1904; this J., 1904, 1080.—T. H.

Ret. J. L. Jackson, Assignor to American Sandstone Machine Machinery Co., Saginaw, Mich. U.S. Pat. 2,207, Feb. 7, 1905.

An arched retort is constructed of sections rivetted together, and under each circumferential series of rivets a "rip-trough" curved to conform to the internal contour of the arch is arranged, in order to convey any used liquid to the sides of the retort. The trough is supported by "jam-bolts" passing through the side of the retort and the bottom of the trough, and having their ends flush with the convex side of the latter.—W. H. C.

Liqs with Gases; Apparatus for Treating —. J. Quarez, Amiens, France. U.S. Pat. 782,622, Feb. 1, 1905.

The liquid and gas are made to pass down a "downflow-column" in which are arranged "deflectors" and "conduit sleeves" forming passages between the deflectors. From the bottom of the "downflow-column," which has a serrated edge, the gas and liquid pass to a communicating "ascension-column." In the latter there are arranged a number of superposed deflectors, having serrated rims, and of varying diameters. The liquid flows from the upper part of the "ascension-column" into a "b-tank," which is provided with an adjustable vertical partition, forming a filtering medium, to keep back any sand and with an outlet pipe for the liquid.—W. H. C.

II.—FUEL, GAS, AND LIGHT.

ENGLISH PATENTS.

Fuel and similar Humid Materials; Apparatus for Treating the Moisture from —. A. H. Higginbottom and A. B. Lennox, Newcastle-on-Tyne. Eng. Pat. 1,5170, March 2, 1904.

The material to be treated is fed on to an endless band, or sprocket chain carrying wooden boards, mounted on suitable pulleys. As the material is carried forward by the band or chain, it is pressed against the exterior of a revolving drum, mounted on a spring-bearing, so that it may give somewhat and allow any hard lumps to pass between its surface and the band without damaging the arrangement. After being compressed, the material leaves the band and is carried forward on the surface of a drum to a point where it is taken off by a scraper and delivered into a shoot.—W. H. C.

Furnaces; Impts. in —. E. Dury and O. Piette, St Gilles, les-Bruxelles, Belgium. Eng. Pat. 27,276, Jan. 14, 1904.

In each lateral wall of a horizontal coke-furnace with vertical flues, a fixed conduit is arranged for the supply of the fuel-gas. The conduits are provided with branches or "tuyères" with valves, operated from without the furnace, either singly or in groups, by means of rods or other convenient arrangement. The rods are arranged in a manner that it is easy to determine which valve is being operated. Further claim is made for constructing the conduits of such elongated section in the direction of length, that the introduction of cleaning hooks is facilitated.—W. H. C.

Manufacture of Illuminating —. B. Dutteneber, Karlsruhe, Germany. Eng. Pat. 2001, Jan. 26, 1904.

U.S. Pat. 340,055 of 1904; this J., 1904, 745.—T. F. B.

Producers and like Apparatus. A. L. Forster, Birmingham. Eng. Pat. 6999, Mar. 23, 1904.

To facilitate the poking of the fuel within the producer, a support is provided, consisting of a ball with a hole through it, a seating for the ball, fixed over the poke-hole, and an adjustable guard for retaining the ball in position and forming a sufficiently gas-tight joint between the ball and its seating. The ball has free rotary movement in all directions. The poker is inserted into the producer

through the bore in the ball, and may then be worked about at any desired angle. When the poker is withdrawn, the ball is rotated on its seating to such a point that the bore does not permit communication between the interior and the exterior of the producer.—H. B.

Gas; Apparatus for Producing — from Pulverisable Fuel. G. Marconnet, Paris. Eng. Pat. 25,404, Nov. 22, 1904. Under Internat. Conv., Dec. 8, 1903.

SEE FR. Pat. 337,514 of 1903; this J., 1904, 484.—T. F. B.

Calcium Carbide; Preparation [Agglomeration] of —. L. Leinss, Paris. Eng. Pat. 4506, Feb. 23, 1904.

SEE FR. Pat. 339,492 of 1904; this J., 1904, 710.—T. F. B.

UNITED STATES PATENTS.

Fuel; [Electrical] Process of Preparing Peat for —. J. W. Vaughan and C. S. Horner, Eaton Rapids, Mich. U.S. Pat. 782,587, Feb. 14, 1905.

THE process claimed consists in first mechanically separating the contained water as completely as possible. The peat is then subjected to the action of an electric current in order to disintegrate it and liberate the water left in it by the mechanical process. The water liberated by the electrical treatment is separated either concurrently or subsequently.—W. H. C.

Coke Oven; Retort —. C. S. Mason, Buffalo, N.Y. U.S. Pat. 782,259, Feb. 14, 1905.

A SERIES of horizontal retort-ovens is arranged with combustion-chambers below, and have regenerators communicating with the latter. There are vertical heating flues between adjacent ovens, communicating by their lower ends with the combustion chambers. Three or more horizontal flues, one above the other, are situated between adjacent ovens, above the vertical flues. The lowest horizontal flue communicates with the upper ends of the vertical flues beneath, and extends from the median line of the ovens to the sides. The upper horizontal flue extends right across the series of ovens. The walls between the horizontal flues have openings, in different vertical planes, to equalize the flow of the gases, and are provided with valves or dampers, or with adjustable refractory blocks, moved by rods introduced through suitable openings in the side walls, for altering the size of the openings in the horizontal partitions.—W. H. C.

[Oil] Gas; Apparatus for Manufacturing —. L. P. Lowe, San Francisco. U.S. Pat. 781,836, Feb. 7, 1905.

Two vertical generators, communicating at the foot with a common combustion chamber, are filled with chequer-work, except at a point midway up each generator, where a mediate chamber is formed in each. Steam and air inlet pipes, and a flue, are provided at the upper end of each generator; an oil inlet pipe enters the combustion chamber; and an oil inlet pipe and gas outlet pipe open into each of the mediate chambers, the two gas outlet pipes entering a common hydraulic seal. All the pipes are controlled by valves.—H. B.

Gas; Apparatus for Manufacturing —, and Recovering By-Products. L. P. Lowe, San Francisco. U.S. Pat. 781,837, Feb. 7, 1905.

Two superposed chambers, filled with chequer work, are connected by means of a gas conduit, in which is interposed a condenser. The upper chamber is fed with oil, the lower one with steam. By means of a flue between the chambers, independent of the condenser, products of combustion can be passed successively through the lower chamber, the flue, and the upper chamber. Gas may also be drawn off from the bottom of the lower chamber without passing it through the first chamber.—H. B.

Gases; Apparatus for Cleaning —. L. P. Lowe, San Francisco. U.S. Pat. 781,838, Feb. 7, 1905.

WITHIN a vertical cylindrical casing is arranged a vertical series of cylindrical chambers alternating with piles of open chequer work. The gas to be washed is admitted

at the base, along with an obliquely directed current of steam, so that a whirling motion is imparted to the mixture; the latter then ascends through the first pile of chequer-work, on to which water is being sprayed, and thus the steam is condensed. In the next cylindrical chamber the gas encounters another obliquely directed steam current, and then rises through another pile of chequer work; and so on till the outlet is reached.—H. B.

Gas Washer. B. T. Mullen, Leetonia, Ohio. U.S. Pat. 782,041, Feb. 7, 1905.

THE gas is admitted into a chamber, enclosed in and forming the upper part of a larger vessel. At the foot of this enclosed chamber is a horizontal plate, from which depends a series of short vertical pipes, which divide the gas stream into small jets that impinge upon the surface of water maintained at a constant level, and contained in the lower part of the enclosing vessel. The washed gas passes out at a side opening in the vessel.—H. B.

Gas Washer. B. T. Mullen, Leetonia, Ohio. U.S. Pat. 782,042, Feb. 7, 1905.

COMPARE preceding abstract. The gas enters at the side of the apparatus, passes down through an annular series of short pipes, impinging upon the surface of the water, and is led out by a central pipe which hangs down into the apparatus.—H. B.

Gas; Method of Purifying Illuminating. —, C. S. Lomax, Everett, Mass. U.S. Pat. 782,403, Feb. 14, 1905.

SEE Eng. Pat. 14,445 of 1904; this J., 1904, 977.—T. F. B.

FRENCH PATENTS.

Briquettes of Coal Dust or Peat; Manufacture of —, G. van der Heyden. Fr. Pat. 346,861, Oct. 7, 1904.

COAL dust or peat is mixed intimately with a small quantity (say, 2 per cent.) of liquid glue; the mixture is moulded into the desired shape; and the briquettes obtained are hardened by leaving them for several hours in a solution of formaldehyde, or by submitting them to the action of formaldehyde vapour.—H. B.

Coke; Treatment of Coal for the Manufacture of —, W. J. Patterson. Fr. Pat. 346,775, Aug. 20, 1904.

SEE Eng. Pat. 17,580 of 1904; this J., 1904, 977.—T. F. B.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, PETROLEUM, AND MINERAL WAXES.

ENGLISH PATENT.

Oils; Process for Reducing the Density of Mineral and Vegetable —, A. Camera di Salasco and C. C. Rovere, Turin, Italy. Eng. Pat. 26,192, Dec. 1, 1904.

MINERAL or vegetable oils are reduced in density, and thereby rendered more suitable for illuminating, heating, and other purposes, by treating them with lime and an acid, such as sulphuric, hydrochloric or oxalic acid. For example, a tar oil of sp. gr. 1.02 may be reduced to a sp. gr. of 0.8 by stirring slowly into it not more than 6 per cent. of its weight of pure sulphuric acid. Not more than 20 per cent. of lime (on the weight of the oil) is then gradually added, with agitation, and the mixture is allowed to stand for some hours.—T. F. B.

UNITED STATES PATENT.

Ammonium Sulphate Saturator. K. Zumpell, Stettin, Germany. U.S. Pat. 782,637, Feb. 14, 1905.

SEE Eng. Pat. 23,379 of 1904; this J., 1905, 81.—T. F. B.

FRENCH PATENT.

Hydrocarbons such as Petroleum and Benzine; Solification of —, G. van der Heyden. Fr. Pat. 346,8 Oct. 7, 1904.

GLUE or gelatin is softened in hot water, and then melted; the petroleum, or other hydrocarbon which is desired to solidify, is then added gradually, with stirring to the molten glue or gelatin, the stirring being continued until emulsion is complete. It is stated that by this method, petroleum can be emulsified with as little as 11 per cent. of its weight of glue. The emulsion is run into moulds, and allowed to set, and the blocks thus formed hardened by treatment with formaldehyde vapour solution, or with tannin.—T. F. B.

IV.—COLOURING MATTERS AND DYESTUFFS.

Diazoamino Compounds; New Synthesis of —, Dimroth. Ber. 1905, 38, 670—688.

ORGANOMAGNESIUM compounds react with alkyl and derivatives of hydrazoic acid according to the equation

The intermediate compounds thus formed react with water to form diazoamino compounds, according to the equation:—

Methylphenyltriazine is obtained by acting on methylmagnesium iodide with diazoiminobenzene in ethereal solution and then pouring into an aqueous solution of ammonium ammonium chloride. The product is an almost colourless crystalline solid and can be distilled *in vacuo*, though with considerable loss. It can be distilled without decomposition in a current of steam produced from water containing caustic soda and a trace of ammonia. As a precaution is necessary, as it is rapidly decomposed by small quantities of carbon dioxide. Its chemical behaviour is that of a tautomeric compound. With some reagents it behaves as diazomethane $CH_3.N_2.NHC_6H_5$, and with others as diazobenzene methanamide $CH_3.NH.N_2.C_6H_5$. It is extremely unstable towards acids, evolving nitrogen and forming ammonia quantitatively. Even carbonic acid causes this decomposition in the cold. With diazobenzene chloride it forms bisdiazobenzene methanamide $(C_6H_5.N_2)_2N_2$. Ethylphenyltriazine was prepared in an analogous manner and showed similar properties. Benzylphenyltriazine can be obtained either from phenylazide or benzylmagnesium chloride, or from benzylazide and phenylmagnesium bromide. It is decomposed by cold hydrochloric acid according to the equation:—

but in other respects acts as a tautomeric compound. It is colourless, and is not decomposed by carbonic dioxide. Methylbenzyltriazine was prepared from benzylazide and methylmagnesium iodide. It was purified by means of the crystallisable silver compound, which re-forms methylbenzyltriazine with sodium sulphide. This triazine is a colourless oil which is more sensitive to acids than carbon dioxide than methylphenyltriazine. It has a fungus-like odour. Methyl- and ethylphenyltriazine have a characteristic odour. Though the partially aliphatic triazines are colourless, their silver and copper compounds are yellow and orange respectively, but its copper compound is faintly yellow.—E. F.

Aniline Solutions; Electrolysis of Acid —, L. Gillet. XI A., page 243.

Nitrogen in Azo-, Azoxy-, and Hydrazo Compounds; Determination of — by Kjeldahl's Method. C. Flamand and B. Prager. XXIII., page 251.

ENGLISH PATENTS.

Colouring Matters or Dyes [Sulphide Dye-stuffs]; manufacture of Blue —. H. C. Cosway and the United Alkali Company, Ltd., Liverpool. Eng. Pat. 440, March 23, 1904.

mol. of *p*-aminophenol hydrochloride and two mols. of *p*-aminophenol are heated together at a temperature of 10°—180° C., till a sample dissolves in alkali with a bl colour. Sulphur is then added in small quantities to the melt (for example, 7½ molecules altogether) at a temperature of 160—220° C.; the mixture is maintained at this temperature until no more hydrogen sulphide is evolved, and is then heated to 220° C. The mass is allowed to cool, and ground. It can be dissolved for use in alkali hydroxide solution, and dyes cotton from a bath containing sodium sulphide and common salt in rich blue shades.

—E. F.

Colouring Matters or Dyes [Sulphide Dye-stuffs]; manufacture of Blue-black to Black —. H. C. Cosway of the United Alkali Co., Ltd., Liverpool. Eng. Pat. 441, March 23, 1904.

BLUE-BLACK to black sulphide dyestuffs are obtained by heating a mixture of sulphanilic acid, *p*-aminophenol, water, evaporating to dryness, raising the temperature, using sulphur, followed by the addition of a solution of sodium hydroxide, and heating at an elevated temperature. For instance, 180 parts of sulphanilic acid, 110 parts of *p*-aminophenol and 50 parts of water are heated with stirring to 100° C., until all the water is driven off. The temperature is then raised to 140° C., and 50 parts of sulphur added in small quantities. The melt is maintained at 140° C., for two hours, and 200 parts of sodium hydroxide solution of 28° B. are then added. The melt is kept at 180° C. for four hours, dried and ground. The product dyes cotton in blue-black to black shades from a bath containing sodium sulphide and common salt. —E. F.

Colouring Matters or Dyes [Sulphide Dye-stuffs]; manufacture of Green —. H. C. Cosway and the United Alkali Co., Ltd., Liverpool. Eng. Pat. 7042, March 23, 1904.

p-AMINOPHENOL hydrochloride is heated to 140°—160° C., with two parts of sulphur for about three hours. A solution of sodium hydroxide is then added; for example, 10 parts of a solution of 28° B., the temperature is raised to about 210° C., and maintained for some time, say, four hours. The crude product may be used directly for dyeing, or may be first purified by solution in water and precipitation with mineral acid. It dyes cotton in green shades from a bath containing sodium sulphide and common salt. —E. F.

FRENCH PATENT.

Chlorinated Amino Bases and Violet Monazo Dye-stuffs for Wool Derived therefrom; Preparation of —. Urbw. vorm. Meister, Lucius und Brüning. Fr. Pat. 39,225, Dec. 18, 1903.

4-AMINO-2,5-DICHLORO-ACIDYLANILIDES are manufactured by nitrating 2,5-dichloroacydylanilides and reducing the resulting nitro-compound. Suitable acydlanilides are obtained by boiling 2,5-dichloroaniline with formic acid or acetic anhydride. Dyestuffs which yield violet-blue shades on wool from an acid bath are obtained either by diazotising a 2,5-dichloro-4-aminoacydlanilide, combining with one molecule of chromotropic acid or chlorochromotropic acid in alkaline solution, and saponifying the resulting dyestuff by boiling with sodium hydroxide solution; or by diazotising 2,5-dichloro-4-nitraniline, combining in alkaline solution with chromotropic or chlorochromotropic acid, and reducing the resulting dyestuff in an alkaline medium. The resulting chlorinated aminoazo-dyestuffs are more stable than the corresponding monochlorinated dyestuffs previously known.—E. F.

V.—PREPARING, BLEACHING, DYEING, PRINTING, AND FINISHING TEXTILES, YARNS, AND FIBRES.

Vegetable Fibres; Action of Dilute Nitric Acid on —. Jardin. Comptes rend., 1905, 140, 314—315.

THE author finds that in the bleaching of linen, after the preliminary treatment in an alkaline solution and then in dilute hydrochloric acid, the long exposures on grass can be replaced by immersions of from five to six hours in cold, dilute nitric acid (5 per 1000). Linen is bleached in one-third of the time that is usually required, and the material is equal in appearance to and stronger than linen bleached by exposure on grass. It is stated also that the treatment with dilute nitric acid renders the substance of the fibre much more homogeneous, and increases its affinity for dyestuffs.—A. S.

Formaldehyde-Hydrosulphite of Sodium. L. Baumann, G. Thesmar, and J. Frossard. Bull. Soc. Ind. Mulhouse, 1904, 74, 348—360.

FURTHER particulars are given regarding the properties of the formaldehyde-sodium bihydrosulphite recently isolated by the authors (this J., 1904, 1211; See also this J., 1904, 657 and 658).

The compound readily crystallises from water in large, transparent, monoclinic prisms. It is rather less soluble in water than formaldehyde-sodium bisulphite, moderately soluble in dilute alcohol, but insoluble in absolute alcohol, ether, benzene, carbon bisulphide, &c. The compound is a powerful reducing agent, but owing to its stability, it hardly reacts in neutral solution at the ordinary temperature. To render it active, it is necessary to heat the solution, or to add to it either ammonia or sodium bisulphite, which, by reacting with the formaldehyde set the bihydrosulphite free. It is considered probable that by the addition of sodium hydroxide and ammonia in excess, the normal hydrosulphite, Na₂SO₂, is formed, but this compound has not yet been isolated.

In preparing the double salt of formaldehyde-sodium bisulphite and formaldehyde-sodium bihydrosulphite, according to the reactions expressed by the equations:—

the first reaction takes place very readily, and the yield is satisfactory. When, however, increased proportions of zinc and sulphuric acid are taken, with a view to increasing the yield of bihydrosulphite, zinc sulphide and sulphur are formed, and the yield is considerably reduced.—E. F.

Gelatins; Comparison of Sizing Qualities of Different —. C. Beadle and H. P. Stevens. XIX., page 248.

UNITED STATES PATENTS.

Dyeing; Apparatus for —. L. Détré, Rheims, France. U.S. Pat. 782,008, Feb. 7, 1905.

SEE Eng. Pat. 4787 of 1904: this J., 1905, 194.—T. F. B.

Dyeing Machine. J. Leisel, Charlotte, N.C. U.S. Pat. 782,147, Feb. 7, 1905.

A NUMBER of nozzles, connected with the liquor-supply pipe, are provided at the bottom of the dye-vat, and are so arranged as to give the liquor a horizontal circular movement in the vat, thus driving the sediment, &c., to the centre of the vat, where it is received in a well, which can be periodically discharged. Perforated plates are provided for supporting and covering the material to be dyed, and a vertical overflow pipe is also provided in the centre of the vat, this latter being connected with the circulating pump which supplies the liquor to the supply pipe. Mechanical details of a device for raising

out of the vat the plate on which the material rests and tilting it to discharge the dyed material, are also claimed.

—T. F. B.

FRENCH PATENTS.

Cellulose: Process of Preparing a Solution of — in Ammoniacal Copper Oxide of Concentration Sufficient for the Manufacture of Artificial Threads. R. Lindmeyer. Fr. Pat. 346,722, Oct. 1, 1904.

COTTON is treated in a dilute ammoniacal copper oxide solution to soften it, and cause it to swell; this solution should be so dilute that no cellulose is dissolved (e.g., it may contain about 9 grms. of copper and 90 grms. of ammonia per litre). After some hours' treatment, the cotton is wrung out, and dissolved in a concentrated ammoniacal copper solution (containing, for instance, 16–18 grms. of copper and 250 grms. of ammonia per litre) at a temperature of 10° C. or under. The solution is filtered, and agitated in an evacuated vessel, the ammonia being collected. Threads made from such solutions are stated to solidify very rapidly in the atmosphere.—T. F. B.

Bleaching Textiles of Vegetable Origin by means of Sodium Peroxide; Process of —. E. Saint-Hilaire and E. de Grousseau. Fr. Pat. 346,831, Oct. 5, 1904.

VEGETABLE fibres may be simultaneously scoured and bleached by means of a strongly alkaline solution of sodium peroxide and sodium silicate. Such a scouring and bleaching solution may be prepared by dissolving eight parts of caustic soda, one part of sodium silicate, and one part of sodium peroxide in 1000 parts of water.

—T. F. B.

Dyeings on Cotton: Process for Brightening —. Manuf. Lyon. de Mat. Col. Fr. Pat. 339,217, Dec. 11, 1903.

BLUE and black shades, produced on cotton fabrics by means of azo dyestuffs, may be effectively brightened by means of Prussian blue. The process may be carried out as follows:—100 kilos. of cotton, dyed with a black dyestuff which can be diazotised, is immersed in a solution of 2 kilos. of sodium nitrite, 6 kilos. of hydrochloric acid, and 3 kilos. of ferric nitrate, and wrung out. It is then treated with a bath containing 400 grms. of toluylene-diamine, 400 grms. of β -naphthol, and 1600 grms. of potassium ferrocyanide. After 15 minutes, 1600 grms. of sulphuric acid are added; the goods are worked about, rinsed and dried.—T. F. B.

VI.—COLOURING WOOD, PAPER, LEATHER, &c.

Sulphide Colours: Application of — in the Dyeing of Chrome Leather. W. Epstein. J. Soc. Dyers and Colourists, 1905, 21, 39–41.

THE author attempted to prepare sulphide dyestuffs by fusing nitro derivatives of benzidine with sodium sulphide and sulphur. Mononitrobenzidine gave a weak black, but the dinitro compound gave a strong black colour. The mono- and dinitro derivatives of diaminodiphenylmethane also yielded sulphide dyestuffs; the products were identical, the second nitro group in the dinitro compound probably being eliminated during the fusion in the form of ammonia. All the dyestuffs prepared were inferior to Immedial Black for dyeing cotton, but were more stable and required less sodium sulphide in the dye-bath. This latter point is important in the dyeing of chrome leather, as the amount of sodium sulphide usually required in dyeing with sulphide dyestuffs, has an injurious action on the leather. The dyestuff prepared from dinitrobenzidine produced on chrome leather a black equal to that obtained with logwood and iron, without the leather being at all injuriously affected. The best results are stated to be obtained by reducing the amount of sodium sulphide in the sulphur melt to a minimum; using only a small quantity of the sulphide dyestuff in the dye-bath; and then "topping" the dyed leather with a basic dyestuff. The shades produced in this way

are extremely fast to washing and to alkalis, and do not "bleed" when the dyed hides are subsequently "fliquored" with an emulsion of alkali, fat and soap.—A.

VII.—ACIDS, ALKALIS, AND SALTS, AND NON-METALLIC ELEMENTS.

Sulphur Trioxide: Arsenic Pentoxide as Catalyst in Formation of —. E. Berl. Z. angew. Chem., 1904, 18, 252–254.

THE arsenic pentoxide was contained, in the form either of a melted coating on the walls, or of a filling of porous granulated substance, in a Jena glass tube 10 cm. long and 18 mm. diameter, connected by a system of capillary tubes and stopcocks with: (1) a manometer; (2) graduated tube with pressure reservoir; (3) a glass globe of 1200 c.c. capacity containing the gaseous mixture to be treated; (4) a mercury pump. By appropriate arrangement of the cocks, the apparatus could be evacuated and then filled with the mixture, either at atmospheric pressure or so as to contain a measured quantity of the mixture. The reaction-tube was heated in a bath to the desired temperature, and speed of reaction measured by observing the diminution of pressure at constant volume (the complete reaction $2\text{SO}_2 + \text{O}_2 = 2\text{SO}_3$ is accompanied by a reduction of pressure to two-thirds of its initial value). The results are summarised as follows:—(1) At temperatures of 300–500° C. sulphur trioxide attacks glass. (2) Lunge and Reinhardt's conclusion that arsenic pentoxide is a catalyst of similar order to ferric oxide, vanadium pentoxide, &c., is confirmed. Its activity diminishes in the early stages, and later on reaches a constant value. (3) The substance reacts more efficiently on gases dried by concentrated sulphuric acid than on gases either moist or more completely dried. (4) The temperature coefficient increases 1.21 fold per 10° C. between 295° and 340° C., 1.19 fold between 340° and 380° C. The case is, therefore, one of diffusion reaction. (5) The reaction speed increased by rise of concentration either of sulphur dioxide or of oxygen, but the increase is greater in the former case than in the latter. The relative speeds in the two cases, reckoned as percentage of sulphur trioxide formed, are almost alike. (6) Sulphur trioxide exerts a retarding influence: no doubt because it forms a layer on the surface of the catalyst, and hinders the diffusion of the reacting gases. (7) The view that the action in the case of a diffusion-reaction is confirmed by the fact that carbon dioxide retards the reaction more than nitrogen. Chemically the two gases would act alike as indifferent diluents, but the greater density and slower diffusion of carbon dioxide cause it to act more strongly in retarding the reaction than nitrogen.—J. T. D.

Nitric Acid: Experiments on the Preparation of Absolute —. F. W. Küster and S. Münch. Z. anorg. Chem., 1905, 43, 350–355.

THE authors attempted to prepare absolute nitric acid by a process of fractional crystallisation in an apparatus so constructed that moist air could be excluded. It was found, however, that although successive fractions began to crystallise at the same temperature, yet the temperatures fell several degrees during the solidification, and the acid obtained was only of 99.4–0.1 per cent. strength. In an apparatus from which even dry air was, as far as possible, excluded, an acid of 99.79 per cent. strength was prepared, but this, when left in contact with dry air, became weaker until it finally contained only 98.67 per cent. HNO_3 . The crystallised acid (m.p. -41.3°C .) in an apparatus was pure white, but on melting it acquired a yellowish tinge even at -41°C ., and the intensity of the colour increased as the temperature rose to that of the atmosphere. These results appear to show that absolute nitric acid exists only in the crystallised condition below -41°C . On melting, it decomposes partially into nitrogen pentoxide and water, which dissolve in the acid, on passing a current of dry air through the solution, the nitrogen pentoxide is removed, until a colourless acid

aining 98.67 per cent. of nitric acid is left, which utilises unaltered.—A. S.

Lithium Carbonate; Solubility of — in Alkali Salt Solutions. G. Geffcken. Z. anorg. Chem., 1905, 43, 7—201.

LITHIUM carbonate, which is but slightly soluble in water,

dissolves more freely in solutions of the alkali salts, especially of ammonium salts; the sulphates of ammonium, sodium and potassium exercising a greater influence than the corresponding chlorides (see figure). In separating lithium in the form of carbonate, therefore, the presence of ammonium salts and salts of dibasic acids is to be avoided as far as possible.—H. B.

Solubility of Lithium Carbonate in Grm.-equiv. per Litre.

Zinc Sulphate; Decomposition and Formation of —, by Heating and Roasting. N. O. Hofman. Amer. Inst. Mining Eng. Trans., 1905, Jan. 117—164.

zinc sulphate was heated in an electric tube furnace to different temperatures, which were ascertained by a

thermo-electric pyrometer. The lowest temperature at which dehydration of the crystallised salt could be carried to practical completion was 263° C., but after heating to constant weight at this temperature (30—40 hours for 2 grms.), about 0.24 per cent. of water still remained,

RAPIDITY OF DECOMPOSITION OF ZINC SULPHATE.

which was not driven off till the temperature of incipient decomposition of the sulphate was reached. This temperature was found to be 528° C. The lowest temperature at which complete decomposition could be effected was 739° C., but a very long time is necessary at this temperature. The diagram shows the effects of temperature and of depth of layer on the progress of the decomposition (a loss of 19.8 of sulphur represents complete decomposition). These experiments, as well as another series in which the rate of rise of temperature with uniform application of heat was plotted, give no indication of the formation of stable basic sulphates as stages in the decomposition of the normal salt. Some basic sulphate is, however, always formed during the decomposition, the amount of sulphur

in this form being, in the early stages of the process, from one-fourth to one-fifth of the amount eliminated.

In another series of experiments, zinc sulphate was heated with carbon. Carbon begins to have some action at 400° C., and the action increases gradually up to 528° C.; but at this temperature the effect of carbon in eliminating the sulphur begins to be opposed by its tendency to reduce the sulphate directly to sulphide. In the most favourable experiments with carbon the 19.86 per cent. of sulphur in the sulphate was reduced to 3.47 per cent., of which 1.41 per cent. was present as sulphide, and the rest as unaltered sulphate.

A number of experiments were also carried out on roasting blends, to see whether it was possible by regulating the temperature to convert the blends largely or completely into soluble sulphate; it was found, however, that the quantity so produced was in all cases very small, 9 per cent. of the total zinc being the largest amount obtained in this form from a raw blend, and 16 per cent. from a dead-roasted blend mixed with pyrites. The reasons are two—the temperature of roasting is above the decomposition point of zinc sulphate, and at the beginning of a roast the product of oxidation is chiefly sulphur dioxide, and to a very small extent sulphur trioxide. Along with the normal sulphate a certain amount of basic sulphate is also formed, the ratio of basic to normal sulphate increasing with the temperature. Ferruginous blends are more difficult to roast than that containing less iron, but it gives under similar conditions of treatment a higher yield of normal sulphate.—J. T. D.

Ferrous Sulphide; Action of Dilute Acids on — A. Lipschitz and R. v. Hasslinger. *Monatsh. f. Chem.*, 1905, 26, 217–225.

THE authors proved both by electrical and by chemical methods that pure ferrous sulphide is insoluble in dilute acids in the cold. Ordinary ferrous sulphide which develops hydrogen sulphide when treated with cold, dilute acid was found to contain metallic iron. This free iron is primarily dissolved by the acid; the hydrogen liberated reduces the ferrous sulphide with evolution of hydrogen sulphide and formation of metallic iron, which latter is again attacked by the acid, and thus acts as a catalyst.—A. S.

ENGLISH PATENT.

Carbonic Acid Gas; Impts. in and Apparatus for the Manufacture of — J. Leslie, Belfast. Eng. Pat. 8377, April 12, 1904.

THIS invention is a development of Eng. Pat. 9142, of 1903 (this J., 1903, 1130). Coke or charcoal is burnt in a furnace, and the gases are forced through a series of purifiers and absorbers, each of which is provided with a finely perforated diaphragm near its bottom, for passage of the gases. The first two purifiers are charged with water, and the third with an alkaline permanganate solution. The absorbing cylinders are charged with an alkali carbonate solution, and each has an immersed steam coil (brought into use as required) with means for cutting any one cylinder out of the series in turn, whereby the work may be rendered continuous. When the solution in any absorber has become bicarbonated, it is at first gently heated, to expel air, and is then sufficiently heated (by the steam coil) to drive off the absorbed carbon dioxide, which gas is led into a neighbouring gasometer.

ENGLISH PATENTS.

Stone, Artificial; Composition of Matter for — C. Brunson, Hamilton, Ohio. Eng. Pat. 18,804, Aug. 1, 1904.

THIRTY-FIVE lb. of cinders or slag, preferably vitrified, other similar insoluble material, ground to $\frac{1}{4}$ in. size, 5 lb. of fine sand, $\frac{1}{2}$ lb. of barium sulphate, 2 lb. of cement and sufficient water to form a thick "slush" are mixed together in a pug-mill, moulded, and allowed to harden.—A. G.

Bricks; Manufacture of — from *Magnesite*. J. Gerster, F. Freund, S. Freund, and T. Imre, Budapest, Hungary. Eng. Pat. 27,857, Dec. 20, 1904.

THE magnesite is calcined until the whole of the carbon dioxide is expelled, and then ground so as to pass through a sieve with meshes of $\frac{1}{4}$ to $\frac{3}{8}$ mm. diameter. The powder obtained is moulded under pressure as usual, and the bricks further burnt.—A. G. L.

UNITED STATES PATENTS.

Plaster; Method of and Apparatus for Calcining — E. A. Simonds, Assignor to Adolph Leitelt Iron Works, Grand Rapids, Mich. U.S. Pat. 781,747, Feb. 7, 1905.

A CONTINUOUS stream of plaster is passed through a series of steam-jacketed and inclined rotating cylinders, the temperature of which is determined by regulating the pressure of the steam, the last vessel being kept at a temperature near the calcining-point of the plaster.

each double-walled cylinder is provided with perforated closing the hollow space, and with hollow hubs connected to heads comprising hollow arms placed opposite perforations. Means are provided for supplying steam to the hub, and for conveying water away from the other. One head is surrounded by a receiving-case carrying curved buckets and having inwardly-curved ends rotating in a case. The other head is surrounded by a discharge with spout. Means for regulating the steam-pressure are also provided.—A. G. L.

Roofing or Sheathing — J. R. Kelly, Quincy, Ill. U.S. Pat. 782,507, Feb. 14, 1905.

Cement is made by mixing 25 per cent. of dehydrated lime, 60 per cent. of dehydrated aluminium silicate, 15 per cent. of subcarbonate of iron, and sufficient fixed oil to insure a proper consistency.—A. G. L.

FRENCH PATENTS.

Slime contained in a mixture of Sand and Lime; Apparatus for Slaking — with Steam. E. Kretz. Pat. 345,914, Aug. 29, 1904.

Sand and lime are mixed, at the same time that the sand is slaked, in a long horizontal mixing cylinder, rotated by a rotating shaft carrying blades fixed at angles. Barely sufficient steam for the slaking is introduced at one end, the other end being kept cold to insure thorough slaking. The sides of the cylinder are kept at a higher temperature than the interior by means of steam-jacketing, in order to prevent the mixture from adhering to them. The product obtained is ready for loading.—A. G. L.

Apparatus for Impregnating and Staining — G. Kron. Fr. Pat. 346,723, Oct. 1, 1904.

A part of the wood at a time is enclosed by a box, within which is placed an annular vessel of some elastic material such as india-rubber. The box is filled with the liquid with which the wood is to be impregnated; and air is forced into the elastic vessel, which expands, and forces the impregnating liquid into the pores of the wood. The elastic vessel may be strengthened by supports of a non-elastic material.—A. G. L.

X.—METALLURGY.

Copper-Zinc Alloys. E. S. Shepherd. J. of Phys. Chem., 1904, 8, 421—435. Chem. Centr., 1905, 1, 428.

REEDS-AUSTEN (Fourth Report of the Alloys Research Committee; this J., 1898, 249) concluded from melting-point determinations that five different solid phases exist in the series of copper-zinc alloys, but the author has succeeded by microscopic examination in recognising six different solid phases. These six different crystalline forms have the following composition:— α , 71—100 per cent. of copper; β , 45—64 per cent.; γ , 31—40 per cent.; δ , 30 per cent.; ϵ , 13—19 per cent.; and η , 0—2.5 per cent. of copper. The crystals vary in colour from bluish-grey to red; they appear to be solid solutions, not chemical compounds.—A. S.

Brasses [Copper-Tin Alloys]; Chilling of — L. Guillet. Comptes rend., 1905, 140, 307—310.

The author determined the effect of chilling bronzes containing from 5 to 21 per cent. of tin from temperatures varying between 300° and 800° C. The results show that in the case of the alloys containing more than 92 per cent. of copper, the breaking stress and elongation are slightly increased by chilling from temperatures between 400° and 600° C. The breaking stress and elongation of the alloys containing less than 92 per cent. of copper showed a sharp rise when the temperature from which the alloys were chilled exceeded 500° C.; this is in agreement with results obtained by Heycock and Neville (see this J., 1896, 8, 1901, 814). The maximum breaking stress was shown by alloys which had been chilled from about 600° C., irrespective of their composition. The maximum

elongation on the other hand was attained by chilling at temperatures which differed according to the composition of the alloy. For example, with the bronze containing 91 per cent. of copper and 9 per cent. of tin, the maximum elongation was attained by chilling from 800° C., whilst for the alloy containing 79 per cent. of copper and 21 per cent. of tin, the corresponding temperature was 600° C. The difference between the breaking stress of the alloy as cast and that of the alloy chilled from the most suitable temperature was greater the smaller the percentage of copper. It is clear that the chilling of bronzes from temperatures between 600 and 800° C. improves considerably their tensile strength, but the influence of this treatment on the resistance of the alloys to friction must also be investigated, more especially as and according to Heycock and Neville, chilling causes the disappearance of the compound ϵ (Cu_3Sn), a very hard substance, which may play an important part in this respect.—A. S.

Aluminium; Use of — for Beer Filters. F. Schönfeld. XVII., page 246.

Zinc-Sulphide Ores containing Iron: Process of Treating —. C. E. Dewey, Assignor to the American Zinc and Chemical Co., Denver, Colo. U.S. Pat. 781,135, Jan. 31, 1905.

THE ore is roasted, placed in water, and heated for a suitable period with sulphur dioxide, air, and steam.—J. H. C.

Agitating Device. W. B. Deyereux, Glenwood Springs, Col. U.S. Pat. 781,406, Jan. 31, 1905.

CLAIM is made for the combination in a metallurgical apparatus of a closed tank divided into communicating compartments, and provided with an agitator in the form of a screw propeller mounted on a vertical shaft, the upper end of which passes through a stuffing-box. A flexible pipe with valved outlet is provided for discharging the liquid contents when desired.—J. H. C.

Ores: Method of Treating —. Hascal A. Hogel and Herbert A. Hogel, New York, Assignors to Hascal A. Hogel and D. Wallace, New York. U.S. Pat. 781,520, Jan. 31, 1905.

THE ore is pulverised and agitated by mechanical means in a solution containing suitable chemicals, which is atomised by heat, currents of air, and steam.—J. H. C.

Ores: Apparatus for Treating —. Hascal A. Hogel and Herbert A. Hogel, New York, the latter Assignor to the said Hascal A. Hogel. U.S. Pat. 781,521, Jan. 31, 1905.

THE apparatus is a combination of a solution tank, a mixing tank, means for delivering a chemical solution to the mixing tank, means for agitating the mixture of ore and solution, and atomising it under the influence of heat, steam, air or oxygen, a filter tank, and a deposition tank, all with suitable connections.—J. H. C.

Precious-Metal-bearing Ores: Process of Treating —. A. H. Brown, Boulder, Colo. U.S. Pat. 781,711, Feb. 7, 1905.

THE ore is ground in presence of cyanide solution; subjected to hydraulic classification by introducing cyanide solution at the bottom of an overflow-tank to produce an ascending current; and then leached with cyanide solution, the dissolved metals being recovered in any suitable manner. The residual ore is subjected to concentration. Claim is also made for a process of treating sulphide ores, which consists first in subjecting the raw ore to the action of a cyanide solution, whereby the precious metals from the more finely divided ore are dissolved, and secondly, subjecting the ore or tailings to concentration, whereby the metals from the coarser ore are recovered.—A. S.

Copper-bearing Rock: Process of Smelting Native —. F. R. Carpenter, Denver, Colo. U.S. Pat. 781,807, Feb. 7, 1905.

THE copper-bearing mineral is mixed with a basic flux such as lime, and with sulphur, or a sulphide material such as iron pyrites, and smelted, whereby a matte is produced of greater sp. gr. than the slag, and containing the copper, and also any gold and silver present.—A. S.

Vanadium: Process of Reducing —. F. R. Carpenter, Denver, Colo. U.S. Pat. 781,808, Feb. 7, 1905.

VANADIUM is extracted from its silicious ores by mixing them with a compound of a metal with which vanadium

will form an alloy, e.g., iron oxide, and a basic flux such as dolomite and fuel, and subjecting the mixture, in furnace, to the action of an air-blast, in such a manner that a high temperature and a reducing atmosphere are maintained. The vanadium and the iron are reduced and form an alloy, whilst the basic flux and the silica unite to form a slag.—A. S.

Furnace: Rotary Ore-Roasting —. F. Heberle, London, and W. Hommel, Lee, England. U.S. Pat. 781,824, Feb. 7, 1905.

THE muffle-furnace claimed, comprises a circular or chamber, the floor of which rotates, a heating-chamber immediately beneath, rotating with the floor of the ore-chamber, and a stationary heating-chamber immediately above the ore-chamber. The lower heating-chamber divided into three compartments, which successively arrive opposite and communicate with the fireplace furnace furnishing the heating gases. Each of the compartments is provided with partitions so disposed that the furnace-gases are caused to travel radially inward to the centre of the heating-chamber, and then radially outward to flues communicating with the upper heating-chamber.—A. S.

Furnace: Metallurgical —. R. L. Lloyd and P. Th. Greatfalls, Mont. U.S. Pat. 781,834, Feb. 7, 1905.

THE furnace comprises a stationary hearth arranged about a vertical shaft, and forming a continuous helical path for the ore. The shaft carries feeder-arms, which are disposed in the spaces between the turns of the helix. A rotary reciprocating motion is imparted to the shaft, and guides are provided so that the movement of the feeder-arms follows the pitch of the helix. The shaft also alternately raised and lowered, in such manner that the feeder-arms are kept out of contact with the ore during their backward stroke. The feeding mechanism is supported by a hydraulic cylinder and piston, and means are provided for counterbalancing the thrust on the piston.—A. S.

Furnace or Kiln for Roasting Ores. G. O. Petersen, Dalsbruk, Russia. U.S. Pat. 781,904, Feb. 7, 1905.

SEE Eng. Pat. 22,162 of 1903; this J., 1904, 22.—T. F.

Furnace: Rotary Puddling or Bushelling —. Stubblebine, Bethlehem, Pa. U.S. Pat. 782,080, Feb. 7, 1905.

THE treating-vessel of the furnace rotates about longitudinal axis, which axis is inclined to the horizon. There is a gas inlet at the higher end of the vessel, and a gas outlet of smaller area than the inlet, at the other end. The vessel is also provided, "on opposite sides of centre of its longitudinal axis," with "suspending means whereby it can be raised and lowered and tilted." "suspending means" are independent of the mechanism for rotating the vessel.—A. S.

Matte or Pyritic Smelting: Method of —. O. S. Garrettson, Buffalo, N.Y., Assignor to Garrettson Furnace Co., Pittsburgh, Pa. U.S. Pat. 782,123, Feb. 7, 1905.

THE matte is bessemerised or converted by means of a blast underneath a column of material containing a flux. The slag produced, flows on to a reverberatory furnace, where it is mixed with sulphur-bearing material and subjected, in a shallow layer, to heat from above, whereby a low-grade matte is produced, which is then taken up the metal or matte contained in the slag. This low-grade matte is led continuously back to the converter.—A. S.

Matte: Method of Converting —. O. S. Garrettson, Buffalo, N.Y., Assignor to Garrettson Furnace Co., Pittsburgh, Pa. U.S. Pat. 782,124, Feb. 7, 1905.

THE slag produced when matte is converted by means of a blast underneath a column of material containing a flux or silicious substances, is freed from accompanying matte by settling, and is then heated by means of a flame playing over its surface, sulphur-bearing material being at the same time added intermittently, whereby a low-

g matte is produced, which combines with any values
ained in the slag. Claim is also made for a method
ultaneously smelting and converting matte, which
ists in regulating the height of the layer of matte
the blast in accordance with the desired degree of
ersion, injecting an oxidising blast in excess of that
h is consumed in converting, heating the excess blast
ausing it to pass through the molten matte, and utilis-
ing, above the layer of matte, in smelting.—A. S.

82; *Apparatus for the Removal and Utilisation of* —
C. King, Marion, Ala., Assignor to J. W. McClure,
ttsburg, Pa. U.S. Pat. 781,887, Feb. 7, 1905.

T molten slag is supplied to a slag-pit constructed with
or more adjacent chambers having walls which slope
rdly near and toward the basal portion. Means are
ided to control the slag inlets, to supply water to the
id as it enters the pit, and to carry off the overflow of
water. A slag-discharging conveyor is placed so as
to avo its inlet end in the basal portion of the pit. A
fic shaft operates the several conveyors in the series,
clutch mechanism is provided to throw them severally
of action, as well as means to govern the inlet to the
conveyor, and to receive and discharge the granulated
id.—A. G. L.

4; *Metallic* — L. H. E. Lacroix, Pont de Chéruy,
ssignor to J. L. Rontin and L. M. E. Mourraille, Lyons,
rance. U.S. Pat. 782,401, Feb. 14, 1905.

8. Fr. Pat. 332,605 of 1903; this J., 1903, 1247.—T. F. B.

als; *Method of Coating* — H. Rodman, Cleve-
land, Ohio. U.S. Pat. 781,230, Jan. 31, 1905.

T metal is cleaned by the action of an alkali metal,
h is electro-deposited on it, and thereafter plunged
in molten bath containing an alkali metal in suitable
portion.—J. H. C.

FRENCH PATENTS.

0; *containing Sulphur; Utilisation of Sulphurous Acid*
ained from — I. Santilippo. Fr. Pat. 346,834,
ct. 5, 1904.

T sulphurous acid which is given off when ores con-
taining native sulphur are treated in furnaces is made
to pass through valved pipes into chambers where it
n be utilised in any known manner, and especially in
the manufacture of sulphuric acid.—J. H. C.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

(A.)—ELECTRO-CHEMISTRY.

line Solutions; *Electrolysis of Acid* — L. Gil-
rist. J. of Phys. Chem., 1904, 8, 539—547. Chem.
entr., 1905, 1, 440.

Electrolysing a solution of aniline in hydrochloric acid,
line Black was formed at the anode, and not chloro-
aine. A similar reaction took place in sulphuric acid
sion. The decomposition-potential of aniline in
hydrochloric acid and in sulphuric acid solution was found
to be the same—0.95 volt, that is 0.3 volt below that of
pe hydrochloric acid and 0.7 volt below that of sul-
phuric acid. Aniline thus acts as a depolariser and forms
the same oxidation-product when dissolved in either acid.
The decomposition-potential of hydrobromic acid is 0.75
v., and therefore less than that of aniline, and as was to
be expected, a bromine derivative of aniline (*s*-tribromoani-
line) was formed by the electrolysis of aniline in hydro-
bromic acid solution. The decomposition-potential of
nitraniline in sulphuric acid solution is 1.43 volts, and
the compound is oxidised less readily than aniline.—A. S.

ENGLISH PATENTS.

Accumulator Plates; Preliminary Treatment of — H.
Leitner, Woking, Surrey. Eng. Pat. 6792, March 21,
1904.

LEAD plates are subjected as anodes to the action of a
high-density current in a dilute solution of a suitable
sulphate to which traces of substances capable of forming
soluble lead compounds are added. (As example, a
solution containing 2 per cent. of sodium sulphate and
2 per cent. of chlorides is mentioned.) After cleansing,
the plates are reduced, by being used as cathodes in a
suitable electrolyte, whilst finally the layer of finely
divided lead is oxidised by exposure to warm air.

Electrolytic Apparatus. A. Wright, Brighton, England.
U.S. Pat. 782,398, Feb. 14, 1905.

THE apparatus described is a mercury electrolytic meter
which consists of a chamber divided into two parts by
a sieve-like mercury receptacle made of a material which
is not wetted by mercury and which has openings so
small that the liquid metal cannot flow through them,
whilst allowing of the free passage of the electrolyte.
This receptacle is corrugated so as to receive mercury
in its depressions only, and is formed with a channel or
channels which permit of the electrolytically-deposited
metal being returned to the receptacle.—A. G. L.

Fuel; [Electrical] Process of Preparing Peat for —
J. W. Vaughan and C. S. Horner. U.S. Pat. 782,587,

Accumulator Plates; Regeneration of Negative —
of reduced Capacity; or Prevention of diminution of
Capacity of new Plates. R. Kieseritzky. Fr. Pat.
346,760, Oct. 3, 1904.

FOR the purpose described in the above title, the author
proposes to use pieces of wood between the positive and
negative plates of an accumulator. Probably owing to
some slight solubility in the electrolyte, they prevent the
agglomeration and consequent loss of activity of the
finely-divided spongy lead. The wood should be pre-
viously freed from injurious organic acids and resin by
treatment with alkaline solutions.—R. S. H.

(B.)—ELECTRO-METALLURGY.

Mercury Distilling Apparatus. J. Pollak. Ann. der
Physik, 1904, 15, 1049—1050. Chem. Centr., 1905,
1, 417—418.

THE apparatus consists of a barometer tube which is con-
siderably enlarged at its upper part, and which opens into
a T-tube. One branch of the T-tube is connected to an
air-pump, and the other, which is bent upwards, to the
receiver for the purified mercury. The barometer tube
is heated electrically by means of a spiral encased in
asbestos. The first portion of the mercury which distils,
collects in a T-tube interposed between the barometer
tube and the pump thus cutting off the latter. The
apparatus needs little attention and yields about 4 kilos.
of purified mercury in 24 hours with a consumption of
10 volts and 29 ampères.—A. S.

UNITED STATES PATENTS.

Copper: [Electrolytic] Process of Producing Pure —, L. M. Lalontaine, Paris. U.S. Pat. 782,143, Feb. 7, 1905.

COPPER-PRODUCING substances or ores, without any previous treatment, are formed into suitable plates by agglomerating with lime, and these are connected together and used as anodes in an electrolytic bath with suitable cathode plates also connected together. The electrolyte is prepared by saturating water with copper sulphate, adding a quantity of sulphuric acid, and then adding "calcined soot" to the filtered liquid. By passing a current of electricity through the liquid, the copper is dissolved at the anodes, and deposited as chemically pure or refined copper at the cathodes.—B. N.

Nickel-Plating: Apparatus for —, J. W. Aylsworth, East Orange, N.J., Assignor to Edison Storage Battery Co., Orange, N.J. U.S. Pat. 781,867, Feb. 7, 1905.

THIS invention relates to an apparatus for electroplating a continuous strip-like iron or steel article, or a connected series of separate articles, and subsequently welding the nickel film on to the metal. The article or articles pass continuously through a chamber in which they are heated electrically in the presence of a reducing atmosphere so as to deoxidise them. The articles then pass continuously through an electrolytic bath, in which they are coated with a metal during transit. After passing through a washing tank they pass continuously through a second heating chamber in which they are electrically heated to a welding temperature in the presence of a non-oxidising gas, and finally through an extension of the heating chamber so that they are cooled below the oxidising point while still surrounded by the gas. A series of pulleys in the plating and washing baths support and guide the strip during transit, and the heating chambers are also provided with pulleys over which the strip passes.—B. N.

XII.—FATTY OILS, FATS, WAXES, AND SOAP.

Cacao Butter: Specific Gravity of —, M. Rakusin. Chem.-Zeit., 1905, 29, 139.

THE specific gravity of cacao butter was given by Hager as 0.945–0.946 at 15° C., and by Dieterich as 0.976 at 15° C. The author has found this value to be 0.9702 at 20° C. and thus confirms Dieterich's results. He points out that cacao butter sinks in castor oil, and must therefore have a greater density than 0.9604 at 20° C. (the value for that oil on Regnault's hydrometer).—C. A. M.

XIV.—TANNING, LEATHER, GLUE, SIZE

Sheep Leather with Chamois-like Finish. R. Bunzl. Der Gerber, 1905, 31, 49–50.

SHEEPSKINS that are damaged on the grain can be finished upon the flesh side. When a highly-glazed leather is required, the skins may be brushed over on the flesh side with a solution of dyestuff, to each litre of which has been added 200 grms. of flour. After drying, they are then glazed by machine.

The goods to be dressed for imitation chamois or fancy leathers, are placed for 5 minutes in a solution of 2 grms. of potassium bichromate dissolved in 6 litres of cold water, washed, slicked out, and dyed in the usual way using basic dyestuffs. The drum and paddle method of dyeing are not to be recommended in the case of these skins. The dyed goods are washed, slicked out, oiled over, and quickly dried. When dry, they are rubbed over with powdered pumice on the flesh side in order to raise the "nap," and are brush-stained on the flesh side with a colour supplementary to that used in dyeing the grain side, e.g., red with yellow, orange with blue, purple with violet. The final finish is produced by rubbing over the flesh side with fine pumice stone.—M. C. L.

ENGLISH PATENT.

Sugar; Treatment or Preparation of —, and *Apparatus for use therein.* E. Shaw, London, Eng. Pat. 4112, Feb. 18, 1904. (Compare this J., 1905, 114.)

CLAIMS are made, in apparatus for use in the preparation of "acrated" or "basket" sugar, for an enclosed chamber or trough wherein hot syrup is caused to crystallise evenly throughout, without being allowed to cool unduly; for the combination of this chamber with a pipe heated externally by steam, and means for forcing syrup through it, and also means for separating the steam from the syrup as it leaves the heated pipe; for another chamber or trough through which the crystallised mass from the crystallising chamber is passed and wherein it is stirred and broken up, steam being thus allowed to escape, but loss of heat from other causes being retarded, the syrupy mass during its passage through this chamber or trough gradually changing into more or less dry, acrated sugar; for the production of sugar by adjusting precisely the proportion of invert sugar present in the syrup, rapidly boiling the solution by forcing it at a suitable speed through a pipe heated externally by steam, and then converting the boiled syrup into saleable sugar by passing it through apparatus as described above.—T.H.P.

FRENCH PATENTS.

Inulin; Manufacture of — from *Artichoke Roots.* J. B. Gailhat. Fr. Pat. 346,837, Oct. 6, 1904.

ARTICHOKE tubers are harvested a short time before they reach maturity, and are treated in the same manner as potatoes in the manufacture of starch, or else they are dried at 100°—110° C. in special evaporators in order to preserve them until required. The dried slices may be boiled and pulped, or ground to flour before extracting the inulin, which is done in the way usual in the case of potato starch.—J. F. B.

"Saccharo-Gum." J. Pernod. Fr. Pat. 339,228, Dec. 21, 1903.

"SACCHARO-GUM" is produced by the viscous fermentation of saccharine liquids, which is set up by the addition of nitrogenous organic matters, such as blood, sewage, &c. The infected liquid is maintained at a temperature of 16°—26° C. with frequent agitation for 15 or 20 days, until sufficient viscosity is obtained. The viscous solution may be utilised direct or after concentration as a substitute for ordinary gum. The gummy matter may be separated in the pure state by dialysis, or by precipitation with alcohol.—J. F. B.

XVII.—BREWING, WINES, SPIRITS, Etc.

Yeast; Production of Sulphuretted Hydrogen by —. H. Will. Z. ges. Brauw., 1905, 28, 108—109.

THE liberation of sulphuretted hydrogen by fermenting wort has been traced by the author and his assistants to the action of yeast on peptones. Likewise Osterwähler has found that a liberation of this gas takes place when yeast acts upon pear- and wine-musts entirely free from sulphur, and analogous results have been obtained by Schander with a number of yeasts and other wine organisms. The latter worker concludes that this property of forming sulphuretted hydrogen is inherent in yeasts, and is manifested more especially when free sulphur is present, but less so when the sulphur is in combination. With one exception, sulphates are more readily acted on by yeast in this direction than organic sulphur compounds. A considerable influence is exercised by the composition of the nutrient medium, the temperature, and the race of yeast. Yeasts with the greatest fermentative activity produce the most gas. In certain circumstances the formation of sulphuretted hydrogen in wine is so extensive as to spoil the flavour, the addition of gypsum to the wine, and growing grapes on soils rich in sulphates, probably favouring the reaction. Some organic sulphur compounds, probably mercaptans, were also detected. Sulphates and especially free sulphur stimulate the

fermentative activity of yeast, which utilises them as food; and the formation of sulphuretted hydrogen is not a simple process of reduction, but one of metabolism. The sulphuretted hydrogen is not produced by the decomposition of albuminoids, but probably from altered sulphur compounds at a stage anterior to their utilisation in the synthesis of albumin. Other microorganisms are able to form sulphuretted hydrogen, *apicidans* yeasts, mycodermæ and a few fission fungi having this power in presence of sulphur, but only the two mentioned in presence of sulphates.—C. S.

Zymase and Alcoholic Fermentation.—A. Harden. J. Inst. Brewing, 1905, 11, 2-13.

THE author has continued his investigations on the effects produced by the addition of substances of a proteolytic nature to yeast cell-juice upon the relative activities of the proteolytic and the fermentative enzymes. In addition to the effects already recorded in the case of blood-serum (see this J., 1903, 432), it has been found that when boiled yeast cell-juice is filtered and added to fresh juice, a very considerable increase in the fermentative power is produced, which increase is greater the greater the proportion of boiled extract added. The boiled extract also has a somewhat irregular retarding effect upon the proteolytic enzyme, but apparently this effect is independent of that on the fermentative enzyme. The addition of varying volumes of boiled juice affects the two enzymes in totally different manners: in the case of the zymase the maximum result is reached slowly, in that of the proteolytic enzyme the maximum effect is very quickly reached, and then remains constant. The nature of the substance which stimulates the alcoholic fermentation is not known, but it is precipitated by alcohol, and is unaffected by boiling but is not produced thereby; it is present equally in fresh and old juice, it is destroyed by incineration, and it will pass through a dialyser. Experiments on the dialysis of fresh yeast cell-juice appear to indicate that the zymase by itself is incapable of effecting alcoholic fermentation, and that the presence of this stimulating substance is necessary before the activity of the zymase is manifested. Membranes of gelatin were prepared in the pores of a Chamberland filter, and the fresh yeast juice was forced through this under a pressure of 50 atmospheres. It was then found that neither the filtrate nor the residue on the filter was capable of setting up any sensible fermentation in sugar solutions, but that when the residue and filtrate were mixed together a fermentation was produced comparable in magnitude with that set up by the original juice.—J. F. B.

Alcoholic Fermentation: Chemical Mechanism of.—H. E. Buchner and J. Meisenheimer. Ber., 1905, 38, 620-630.

THE present investigations confirm the conclusions previously drawn by the authors (see this J., 1904, 262) that the alcoholic fermentation of sugar by yeast cell-juice takes place in two stages, with the formation of lactic acid as an intermediate product. It is proposed to confine the name of "zymase" to the enzyme which splits up the sugar into lactic acid, and to call the complementary enzyme which splits up the lactic acid into carbon dioxide and alcohol, "lactacidase." The conditions under which the equilibrium between the two enzymes, as they occur in yeast juice, can be disturbed so that lactic acid is either formed, or destroyed, are still obscure. But it would appear that the addition of much sugar, as also of lactic acid would favour the destruction of the latter. Cell juices prepared in the summer and those with low fermentative power also appear to favour the destruction of lactic acid, whilst those prepared in the winter and those with high fermentative power generally show an increase in the quantity of lactic acid after fermentation. The lactic acid produced during fermentation was, in all cases, the inactive modification. The assumed initial production of a dihydroxy- γ -ketonic acid (*loc. cit.*) is not confirmed; it is more probable that the primary product of the decomposition of dextrose may be methylglyoxal.

Acetic acid appears to be a characteristic product of the cell-free fermentation of sugar, quantities ranging from 0.01 to 0.33 per cent. of free acetic acid having been observed in the fermented liquids.

Lactic acid is produced by the action of caustic potash solution upon dextrose, both in daylight and in the dark, e.g., when 10 grms. of dextrose, 10 grms. of caustic potash and 200 c.c. of water are kept for 11 months.

By digestion of invert sugar with concentrated caustic soda for four days, small quantities of ethyl alcohol were produced.

Lastly, when calcium lactate was subjected to distillation with slaked lime, considerable quantities of ethyl alcohol were obtained, together with iso-propyl alcohol, the latter resulting probably from the reduction of acetone.—J. F. B.

Mash Tun: Internal Rakes in the.—A. H. Lee. J. Inst. Brewing, 1904, 10, 533-535.

THE provision of internal rakes in the mash tun is necessary, in the old method of mashing, for mixing grist with the water, but even with more modern mash appliances, rakes are desirable for levelling the goods discharged from the mashing machine, and to prevent the solid portion heaping up under the delivery when the liquid runs to the opposite side. No mashing plate is perfect without an underlet, by which the temperature may be raised at any moment by forcing hot liquid through six or eight tap-holes in the bottom. In the method of raising the temperature the action of the rake will be only local, unless the goods are stirred during underlet, and some portions of the mash will remain at the relatively low initial temperature for a dangerous long time. In addition, the uniform distribution of heat will increase the yield of extract by rupturing starch granules, which would otherwise escape. Finally the judicious use of the rakes and underlet will cure the tendency for the mash to "set dead" on the bottom, the lifting of the goods off the plates will enable the water to run off more freely. The existing form of rake is capable of some improvement: the best arrangement would be the usual arm with teeth on one side of shaft, and on the other side, in a line with it, a spoon-shaped or perforated blade, which would lift the water from the bottom.—J. F. B.

Fusel Oil: Production of.—H. H. Pringsheim. Ber., 1905, 38, 486-487.

THE author confirms the observation of Emmerling (J., 1904, 1107) as to the existence of a bacillus on potato which forms fusel oil. When pieces of American potatoes were digested under water at a temperature of 35° for some days, three classes of organism were isolated from the slimy mass, *viz.*, a round coccus, an organism apparently identical with *B. mesentericus vulg.*, and a fusel oil potato bacillus. This last is a motile rod-shaped bacillus which converts potatoes into slime with copious evolution of carbon dioxide and hydrogen, and production of amyl alcohol. When spores are produced, the rods swell up into club-shaped cells, each containing several spores. The spores survive the process of heating at 80° C. for 10 minutes, by which treatment a preliminary purification of the cultures may be effected. The colonies grow only slowly on agar plates, and have a silvery lustre with indefinite edges. The bacillus is not an obligate anaerobe; it liquefies gelatin rapidly. No growth or fermentation takes place in potato media when 10 per cent. of alcohol is added; it would, therefore, appear unlikely that this bacillus is responsible for the production of fusel oil in distillery washes.—J. F. B.

Aluminium: Use of.—for Beer-Filters. F. Schönlank. Woch. für Brau., 1905, 22, 79-80.

THE author finds that when beer is left for some time in a filter made of cast aluminium contained in a copper casing, electrolytic action takes place, and the beer becomes very turbid. There is a considerable proportion of aluminium matter in the deposit, which contains also phosphoric acid, a large amount of alumina, traces of iron and tin oxide (from the solder). If the copper casing is replaced by one of glass, the aluminium is only slightly attacked, and the beer shows only a very slight turbidity or none at all.—T. H. P.

Effects of Various "Fining" Agents on the Composition of —. K. Windisch and T. Roettgen. *Z. Nahr. u. Genussmittel*, 1905, 9, 129—133.

Authors have tested the effects of isinglass, gelatin, albumin and "Spanish earth" (a species of China clay) on the composition of wine when they are added for the purpose of clarification. The total acidity, dry extract, nitrogen and nitrogen were determined before and after in the case of both red and white wines. The results showed that the total acidity, extract and ash were not affected by the clearing agents, with the exception of albumin slightly increased the extract and ash of red wine. The tannin in the case of the red wine of the white wines was distinctly lowered both by nitrogenous fining agents and by the Spanish earth. In the case of one of the white wines, however, the proportion of tannin was slightly increased, without any reason. In the case of wines prepared from grapes the removal of tannin by finings may be very considerable. Bad samples of Spanish earth, containing carbonate, may reduce the acidity of the wine. The proportion of nitrogen was in all cases practically unchanged by the fining agents.—J. F. B.

Musts; Preparation of Practically Sterile —. Perrier. *Comptes rend.*, 1905, 140, 324—325.

Apples are washed with water, immersed for 5—10 minutes in a dilute aqueous solution of formaldehyde (8 per 1000), again washed with water, and allowed to dry. The must is prepared from the fruit in the usual manner, except that the presses, &c., are first disinfected with a 4 per 1000 solution of formaldehyde. The must obtained in this way are sterile with respect to bacteria, and are similar in taste and composition to those obtained in the usual manner; some specimens have been obtained from Rennes to Buenos Ayres and back without undergoing fermentation. When they are sown with yeast, fermentation proceeds in a uniform manner, and cider of equal quality is produced. Among the advantages claimed for this treatment are that musts can be kept from one year to another in view of a possible scarcity of apples; and the production of uniform quality can be freshly prepared at any period of the year. (See also this J., 1904, 73; 1905, 100.—A. S.)

Brandy. O. Hehner. *Analyst*, 1905, 30, 36—43.

The author protests against the tendency to generalise the conclusions formulated in the report of the "Lancet" Commission on Brandy (see this J., 1903, 433). That report deals solely with the production of Cognac brandy, produced in the Charentes district in a more or less primitive manner by pot-still distillation without much purification. Liquors equally entitled to the name of "brandy" are, however, produced in other districts and in other countries, from other varieties of grapes, by other types of distillation, and are distilled by other and frequently more perfect methods of distillation. Since the character and flavour of all spirits depend solely on the nature and quantity of the impurities left in them by the method of distillation employed, it is impossible to apply to these other brandies the same analytical criteria applicable in a strictly limited degree to brandies produced in the Cognac district. These criteria consist in the establishment of certain limits for the "coefficient of impurities" and for the ratio of higher alcohols to esters. But it has been conclusively proved from published analyses that the proposed limits (*viz.*, 300 for the "coefficient of impurities" and 80 for "ethers" per 100,000) cannot be rigorously maintained even for genuine Cognac brandies, since they depend entirely upon more or less accidental conditions. These coefficients are capable of useful application under proper restrictions for products made in the same way from approximately constant raw materials, but they are absolutely misleading as a test for spirits "distilled from the grape" in a general sense, and cannot possibly form the basis of an official standard of authenticity. The question of determining whether a spirit is genuine brandy is beyond the power of chemical analysis; grape spirit differs from other spirits only in its flavour of its residual impurities, and the matter must be left to the opinion of the expert taster.—J. F. B.

FRENCH PATENTS.

Cell-Contents [Yeast]; Extraction and Preparation of Organic —. H. C. Empis. *Fr. Pat.* 346,862, Oct. 7, 1904.

The cells are mixed with water, to which reagents may be added if desired, and the fluid or semi-fluid mass is projected with considerable velocity through capillary tube against an obstacle, whereby the cell-walls are ruptured and the juices are liberated. The liquid is then subjected to successive freezings and thawings in order to fractionate the products, which may also be concentrated by evaporation under vacuum, or dried.—J. F. B.

Musts; Preservation and Sterilisation of — before Fermentation. E. J. B. J. Dequien. *Fr. Pat.* 346,867, Oct. 7, 1904.

The musts are rapidly evaporated to dryness before fermentation, by spreading them in thin layers over a surface heated to a temperature a few degrees above 100° C, and scraping off the film of solid matter.—J. F. B.

XVIII.—FOODS; SANITATION; WATER PURIFICATION, & DISINFECTANTS.

XIX.—PAPER, PASTEBOARD, Etc.

Gelatins: Comparison of Sizing Qualities of Different — C. Beadle and H. P. Stevens. Paper and Pulp, 1905, 10, 69–77 and 105.

The authors give the results of the examination of several samples of commercial gelatins, classifying them according to their reputed origin, relative prices, colour and transparency of sheets, ash and increase in weight by soaking in water. Jellies were also made containing 5 per cent. of air-dry gelatin, and these were classified according to their colour, transparency and stiffness.

A series of sizing tests was then carried out to determine the increase in strength imparted to one and the same waterleaf paper by equal quantities of the various gelatins under similar conditions. The waterleaf selected was composed of two-thirds cotton and one-third linen; it was exceptionally constant in its tensile strength in both directions. Sheets of known weight were carefully sized in 5 per cent. solutions of the gelatins heated to 131° F., every effort being made to ensure equal absorption. This was, however, impossible, so the results of subsequent mechanical tests had to be corrected by calculation in proportion as the percentage of gelatin in the paper differed from 5 per cent. By this method the gelatins were classified according to their relative strength-giving qualities; these qualities were in no way proportional to the relative prices of the gelatins, neither was the stiffness of the jelly any indication of the strength-giving power. The stiffness of the jelly does, however, indicate to a large extent the sizing qualities, i.e., the ink-resisting qualities, of the gelatin. It was found as a rule that the closer the gelatin approached to the "glue" class, the greater was its strength-giving quality, whilst the higher its ink-resisting power, the lower, apparently, was its strength-giving quality.—J. F. B.

ENGLISH PATENTS.

Paper: Manufacture of Many Coloured, Marbled, or Unequally Mixed —, and Apparatus therefor. O. Murray. London. From Farbwerke vorm. Meister, Lucius, und Brüning, Hoechst on the Maine, Germany. Eng. Pat. 6849, March 21, 1904.

PULP dyed with the colour of the desired marbling is allowed to run, with much water, down an inclined plane, on to a sheet of wet paper, dyed another colour, as it comes from the paper machine. The pulp is prevented from penetrating the sheet of paper by the usual vacuum boxes, which operate on the paper shortly after the pulp has come into contact with it. Suitable apparatus for carrying out this operation consists of a vessel into which the pulp and water flow, supported above the wire cloth over which the paper passes. This vessel is provided with a stirrer and baffle plates, to give the pulp a circuitous flow; the pulp then passes down an inclined plane on to the sheet of dyed paper, producing a marbled effect. The effect may be varied by altering the inclination of the plane down which the pulp runs.—T. F. B.

Pyroxylin, Collodion Cotton, Celluloid, and the like: Manufacture of Coherent and Opaque Films, Sheets, or Masses of —. C. D. Abel, London. From Act.-Ges. f. Anilinfabrikation, Berlin. Eng. Pat. 9962, April 30, 1904.

COHERENT, opaque white films or masses are obtained by allowing a solution of pyroxylin, collodion cotton, or celluloid in suitable solvents to evaporate. By varying the concentration of the solutions, it is possible to produce either a brilliant or a dull mass. Coloured opaque masses may also be produced by adding a dyestuff to the solution. For example, by allowing a solution of 20 parts of celluloid in 100 parts of ethyl acetate and 120 parts of methyl alcohol to evaporate at the ordinary temperature, a brilliant, white layer, resembling enamel, is produced. A dull white layer, of very fine grain, is obtained by diluting the above solution with 130 parts of methyl alcohol, and allowing it to evaporate. Films or sheets thus produced are suitable for covering glass, wood, leather, or paper.

FRENCH PATENT.

Cellulose: Process of Preparing a Solution of Ammoniacal Copper Oxide of Concentration suitable for the Manufacture of Artificial Threads. R. Linka. Fr. Pat. 346,722, Oct. 1, 1904. V., page 238.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES, AND EXTRACTS.

Rare Earths: Bibliography of the —. R. J. M. Z. anorg. Chem., 1905, 43, 416–480.

THE bibliography relates to the cerite and yttria and to thorium, but does not include references to art on radio-activity and on the discovery, properties and analysis of minerals containing rare earths. It covers the period between the year 1751 and the beginning of the present year.—A. S.

Mercury Distilling Apparatus. J. Pollak. XI. 1, page 243.

Menthone and Menthyl: Synthesis of —. A. H. and C. Martine. Comptes rend., 1905, 140, 130—

THE authors have succeeded in preparing menthone the methyleyclohexanone derived from pulegone. Menthyleyclohexanone, in which one atom of hydrogen has been replaced by sodium by heating it with sodium amid a suitable solvent such as ether, is treated with isopropyl iodide and the mixture heated. When the reaction is complete, water is added, and the ethereal layer separated and fractionated. In this way menthone is obtained, and from it, by reduction with sodium in alcoholic solution, menthol is produced. The formation of menthone from sodium-methyleyclohexanone takes place according to the equation:—

—A.

Thymomenthol and its Derivatives. L. Brunel. Comptes rend., 1905, 140, 252–253.

THYMENTHOL is readily obtained by hydrogenating thymol by the Sabatier-Senderens reaction, the results being obtained at 160° C.

Pure thymomenthol is a colourless syrupy liquid, with a strong odour of peppermint; it has the sp. gr. 0.823 at 0° C., and crystallises at low temperatures to a solid which melts between –5° and 0° C.; it boils at 215° C. and when exposed to the air, it readily volatilises at no temperatures without forming crystals. When heated with phosphoric anhydride or potassium hydrogen sulphate it is dehydrated, yielding a tetrahydrocymene, thymene, sp. gr. 0.823 at 0° C.; b. pt. 167°–168° C., similar in character to menthone. Thymomenthol forms esters with acids; in consequence of transformation at the time of esterification these esters are those stereoisomerides of thymomenthol; the alcohol formed by hydrogenation is, therefore, designated α -thymomenthol, that liberated from the esters, β -thymomenthol. The acid succinate and phthalate of β -thymomenthol have been prepared. The former, $\text{COOH} \cdot \text{CH}_2 \cdot \text{COO} \cdot \text{C}_{10}\text{H}_{16}$, crystallises from light petroleum spirit in fine colourless and odourless needles; m. pt. 80°; they are soluble in alcohol, and in hot light petroleum spirit—from the latter being almost completely precipitated on cooling. It is soluble in dilute alkaline solutions, forming salts. The acid β -thymomenthyl phthalate forms large colourless, odourless prisms; m. pt. 128° C., is very soluble in alcohol, chloroform and dilute alkaline solutions.

β -thymomenthol crystallises in long needles having the appearance and odour of menthol. It melts at 11° C. and boils at 217° C. It dissolves in most organic solvents, and volatilises less rapidly in the air than α -thymomenthol, so that by exposing a mixture of the two alcohols to the air the α -thymomenthol is entirely volatilised in a few

leaving β -thymomenthol as a crystalline residue. β -thymomenthol gives esters with acids which are identical with those given by the α -alcohol, showing that the isomerisation is effected solely on the alcohol function. Both α - and β -thymomenthol give the same ketone, thymomenthone, $C_{10}H_{18}O$. They are probably racemic forms, but possessing three asymmetric carbon groups.—J. O. B.

Santonin; The Oxonium Nature of —. E. Wedekind and A. Koch. Ber., 1905, 38, 421–428.

The authors discuss the chemical character of santonin, and conclude that it forms oxonium salts. It is pointed out that santonin contains the grouping CH_2CO , and ketones have a particular tendency to salt formation. Desmotropo-santonin, the enolic isomeride of santonin, on the other hand, shows not the slightest tendency to salt formation. It is interesting to note that the toxic action (thread worms) of santonin appears to have some connection with the basic nature of the CH_2CO group. It contains, since the enolic form, (desmotropo-santonin) which the corresponding group is $CH_2CH(OH)$ has no such properties, and is also non-toxic. Santonin may be regarded as an alkaloid which contains no nitrogen. See also this J., 1898, 867; 1903, 509.—A. S.

Strychnine Salts; Optical Behaviour of Solutions of —. Minguin. Comptes rend., 1905, 140, 243–245.

The action of solutions of strychnine salts on polarised light is observed with solutions of the base in a solvent consisting of one part of absolute alcohol and two parts of ethyl alcohol in the presence of, first, a molecular equivalent of various acids; and second, excess of these acids. It is found that the reading in many instances differed materially from that required theoretically by the amount of acid present. It would appear that a kind of dissociation of the strychnine salts takes place, which is more pronounced with weaker acids than with stronger. It is found that in a homologous series of salts, the permanent rotation was practically constant for a given molecular concentration; in the case of strychnine or β -hydroxybenzoate, the permanent rotation was notably greater than in the corresponding meta- or para-salts. Also, as has been previously shown, the double refraction exercised a marked influence on the rotation of the salts in which it occurred, as was seen by comparing the permanent optical rotation of strychnine succinate, tartrate and fumarate and of butyrate and crotonate.—J. XXII.—EXPLOSIVES, MATCHES, Etc.

Explosion; Circumstances attending an —, which occurred in an Ironmonger's Shop at Newcastle Lydyn, in the County of Carmarthen, on the 25th Nov., 1904. By Capt. J. H. Thomson, H.M. Chief Inspector of Explosives.

THE explosion took place in a fire-proof safe containing some 20 lb. of gunpowder. The door of the safe was not locked and it is probable that it was not completely closed. The most probable cause of the explosion was the fall of some iron or steel article displaced from one of the upper shelves. Any such article falling on the concrete floor would be very likely to ignite the powder grains which undoubtedly must have been spilt on the floor in front of the safe, seeing that it was the custom

to sell blasting powder out of a 25 lb. bag, in which it was served by means of a scoop. This was a contravention of the Order in Council requiring "that no package containing more than 1 lb. of explosive shall be covered on registered premises." It is suggested that the space around or in front of fireproof safes containing explosives should be covered with lead or hucolum.—G. W. McD.

ENGLISH PATENTS.

Explosives. J. C. Mitchell, Reynolds, Ind., U.S.A. Eng. Pat. 23,973, Nov. 5, 1904.

It is claimed that the constituents of sandalwood soluble in alcohol have the property of preserving explosives composed of oxygen-yielding materials and carbonaceous materials from damage by moisture, and that such explosives have an increased propulsive effect and a higher degree of safety. Cane sugar (30 parts) and milk sugar (10 parts) are mixed and heated to 100° C. To this is added an extract made by digesting sandalwood (4 parts) with alcohol (6 parts). After standing for ten minutes potassium chlorate (50 parts) is added, and the whole thoroughly incorporated, dried and granulated.

—G. W. McD.

Explosive Compounds and Method of Manufacturing same. C. A. Allison, London, From A. Muller-Jacobs, Armand Heights, U.S.A. Eng. Pat. 27,162, Dec. 13, 1904.

SEE U.S. Pat. 777,125 of 1904; this J., 1905, 44.—T. F. B.

Explosives; Manufacture of —. L. Lheure, Paris. Eng. Pat. 27,166, Dec. 13, 1904.

POWDERED potassium chlorate (88—90 parts) is stirred up with molten paraffin (10—12 parts) until it acquires the appearance of mortar. By pressing the mass through sieves it can be obtained in the form of granules or powder. The explosive is said to be non-sensitive to shock and friction, but is exploded by a 1.5 grain fulminate detonator. Claim is made for the use of paraffin with chlorates without the employment of any other combustible body.

—G. W. McD.

Detonating Tubes; Manufacture of —. for use in Blasting Operations. L. Lheure, Paris. Eng. Pat. 27,167, Dec. 13, 1904.

A TUBE of lead or tin, of suitable internal diameter, is filled with melted trinitrotoluene or trinitrobenzene. When the nitro compounds have solidified, the tube may be reduced to any required diameter by successive drawing operations in a draw-plate. These tubes are not sensitive to shock or friction but may be exploded by a detonator of 1.5 grains of mercury fulminate.—G. W. McD.

Explosive or Blasting Compounds. G. Dittmar, Washington, U.S.A. Eng. Pat. 29,056, Dec. 30, 1904.

PARAFFIN or stearin (50 parts) and rosin (25 parts) are mixed together, heated, and the liquid brought to a temperature of 110°—150° C. Nitroglycerin (25 parts to 100 parts), previously heated to 50°—60° C., is then run in and the whole stirred continuously until solidification begins, otherwise the nitroglycerin, being suspended in the state of an emulsion in the liquefied carrier, would separate out. If desired, the ingredients of ordinary black powder can be incorporated in the fused blasting compound. The finished explosive is said to be unaffected by frost, and can be used in the winter without thawing.

—G. W. McD.

INORGANIC QUANTITATIVE.

Sulphurous Acid in Alkaline Solution; Iodometric determination of —. O. Ruff and W. Jeroch, Ber., 38, 409—419.

Two methods have been hitherto proposed for the titration of sulphurous acid in presence of sodium bicarbonate: namely: (1) direct titration with iodine solution; (2) addition of iodine solution in excess, the excess being titrated with sodium thiosulphate solution. The first method is inaccurate as the sulphurous acid is largely oxidised by the oxygen of the air in presence of the iodine ions which act catalytically. The second method only gives correct results if by chance the error mentioned is compensated for by the fact that the sulphate solution is oxidised by iodine in alkaline solution with partial formation of sulphuric acid. It is, therefore, quite unreliable. Reliable results are obtained by titrating with iodine solution in an atmosphere of carbon dioxide in presence of mannitol (10 to 20 per cent.). It is not to be titrated directly, but if excess of iodine be added it may be titrated back with arsenious acid and not with sodium sulphate.—E. F.

Silver; Separation of —, from Lead. H. Liebermann, Ber., 1905, 38, 566—568.

THE substance having been dissolved, with addition of tartaric acid if necessary, the filtered solution is neutralised, and ammonium acetate added. Any basic lead which may precipitate, is dissolved by means of acetic acid, and the liquid heated to boiling. A few drops of solution of quinol (hydroquinone) (2 c.c. of a 4 per cent. solution to 0.1 gm. of silver) are added, when the silver is precipitated in the metallic state. After subsiding the liquid is filtered, the precipitate on the filter washed with water containing 5 per cent. of ammonium nitrate, dried, ignited, and weighed. Cadmium does not affect the process, but copper and bismuth are partly either precipitated or precipitated as phenolates. If these latter metals are present, the ignited precipitate is placed in a beaker, a portion adhering to the crucible being dissolved in acetic acid, and the solution washed into the beaker, the residue dissolved in nitric acid, and the silver precipitated as chloride, any co-precipitated bismuth being removed by nitric acid according to Fresenius' directions.—J. T.

Molybdenum Trioxide and Vanadium Pentoxide; Determination of —, in presence of each other. B. Mann, Ber., 1905, 38, 600—603.

VANADIUM pentoxide is reduced by zinc to dioxides of magnesium to trioxide; but molybdenum trioxide is either easily reduced to sesquioxide. If then, equal volumes of the solution containing the mixed oxides be placed in flasks fitted with Bunsen valves, by means of hydrochloric acid and zinc, and magnesium respectively, and titrated with permanganate, the difference between the amounts of permanganate used represents that necessary to convert the vanadium present from V_2O_5 to V_2O_4 ($2KMnO_4 = 5V_2O_4$). The amount of vanadium present being thus ascertained, the amount of molybdenum may be calculated from either of the experimental results.

MnO_4 converts $5\text{V}_2\text{O}_3$ into $5\text{V}_2\text{O}_5$; 6KMnO_4 converts O_2 into $5\text{V}_2\text{O}_5$; 6KMnO_4 converts 5MgO_2 into 10O_3 . With about 0.25–0.5 grm. of substance 45 c.c. of hydrochloric acid of sp. gr. 1.19 are used; solution is heated with zinc or magnesium for 1 to 2 hours, poured into a 500 c.c. porcelain basin, containing c.c. of boiling water in which has been dissolved grms. of manganous sulphate, and titrated with N/20 manganate, stirring continually.—J. T. D.

Molybdenum Compounds: Reduction of — by Magesium in Sulphuric Acid Solution. B. Glasmann, *ibid.*, 1905, 38, 604–605.

THE possibility of determining molybdenum by reducing the trioxide with zinc in sulphuric acid solution titration with permanganate, is disputed, the author states that it can be done quite well by substituting magnesium for zinc. The substance is gently heated for 1/2 hr. in a flask provided with a Bunsen valve, with mesium and a sufficient quantity of sulphuric acid (5), poured into a capacious porcelain basin, diluted with about 300 c.c. of water at 30°–40° C. containing little sulphuric acid and titrated with N/20 permanganate.—J. T. D.

Ammonia in Drinking Water: New Method of Determining —. Trillat and Turchet. *Comptes rend.*, 1905, 140, 374–377.

The method proposed, is based on the formation of nitrogen gas when an ammoniacal solution is treated with potassium iodide and an alkali hypochlorite. The nitrogen gas imparts an intense black coloration to the solution, the depth of colour depending on the amount of ammoniacal solution. To determine the amount of the latter in water, 20 to 30 c.c. of the water (or distillate) are placed in an ordinary Nessler cylinder and three drops of a 10 per cent. solution of potassium iodide and two drops of a concentrated alkali hypochlorite solution are added. The authors use commercial *eau de Javel*. The coloration obtained, is compared with that produced by known amounts of ammonia, as in Nessler's process. In cases where the black coloration is very faint, and may be obscured by the colour of the liberated iodine, a slight excess of the hypochlorite solution can be added to dissolve the iodine. This excess must be very small, or the nitrogen iodide will also dissolve. No black coloration is obtained with solutions containing amino compounds, such as the fatty and aromatic series, ureides, pyridine bases, nitrates or nitrites. All ammonium salts, however, give the reaction. As the latter is not affected by the presence of albuminoid matter or sulphides, the saline ammonia may be directly determined in drinking water without previous distillation. The results obtained by the above method, agree closely with those furnished by Schloesing's process.—W. P. S.

ORGANIC—QUALITATIVE.

Polenske's New Butter-Value [Detection of Coconut Oil in Butter] —. A. Hesse. *Milchwirtschaftl. Centralbl.*, 1905, 1, 13–20. *Chem. Centr.*, 1905, 1, 66–567.

The author finds that besides using an apparatus of the prescribed dimensions in carrying out Polenske's method (S. J., 1904, 387), it is of still greater importance to use pumice of uniform size for the prevention of bumping. Fine powder is recommended. If pieces of pumice of uniform size be employed, acids distil over which would otherwise remain in the distilling flask, and the results are thus considerably affected. The author's results indicate that the upper limit for the new butter-value pure butter should be about 0.8 higher than that given by Polenske. Tests with butter procured from one and the same dairy during a period in which a change of order was made, showed that in certain cases the new butter-value varies considerably, whilst the Reichert-Meissl value is only affected to a much smaller degree.—A. S.

Aldehydes: New Reaction of —, and Isomerism of their Oximes. A. Conduché. *Comptes rend.*, 1905, 140, 434–436.

BENZALDEHYDE when treated with a dilute aqueous

solution containing hydroxylamine hydrochloride and potassium cyanate in equimolecular proportions, yields a crystalline substance of m. pt. 125° C. Similar substances have been obtained from other aromatic aldehydes, from furfural, and from cinnamal, but none from ketones. The author attributes to these products the constitution expressed in the following equation:

Of the two isomeric forms of hydroxyurea yielded by a mixture of hydroxylamine salt and potassium cyanate, Francesconi and Parrozzani's form is alone operative in this reaction.

Aluminium amalgam reduces these substances, giving the corresponding substituted urea (benzylurea in the case of the benzaldehyde derivative). Weak acids do not affect these compounds, but strong acids (aqueous hydrochloric acid) decompose them, regenerating the original aldehydes. Alcoholic hydrochloric acid yields (from the benzaldehyde derivative) benzamide, ammonium chloride, and carbon dioxide. Dilute aqueous or alcoholic potassium hydroxide yields β -benzaldoxime and potassium cyanate. This reaction is reversible, but α -benzaldoxime is without action on potassium cyanate, and the two oximes can thus be distinguished. This difference is made clear in favour of the view that the isomerism of these oximes is structural, not stereomeric.—J. T. D.

ORGANIC—QUANTITATIVE

Nitrogen in Azo-, Azoxy-, and Hydrazo- Compounds: Determination of — by Kjeldahl's Method. C. Flamand and B. Prager. *Ber.*, 1904, 38, 559–560.

THE following modification of Kjeldahl's method is given for determining the nitrogen in these classes of substances. From 0.15 to 0.2 grm. of the substance is dissolved in 10 c.c. of alcohol in a long-necked flask of 500 c.c. capacity. After adding 0.5–1.0 grm. of zinc dust and 2–5 c.c. of concentrated hydrochloric acid, the contents of the flask are heated until colourless. This usually takes but a few minutes. Ten c.c. of concentrated sulphuric acid and 0.5 grm. of crystallised copper sulphate are now added, and the heating continued until white fumes are given off. About 6 grms. of potassium sulphate are then added, and the whole heated until a clear green solution is obtained. This is distilled as usual. By the use of this method the authors obtained the correct amount of nitrogen in *p*-oxyazobenzene, *p*-dimethylamino-azobenzene, azobenzene-acetoacetic ester, *p*-bromo-azobenzene-*p*-ethoxyazobenzene-oxalacetic ester, *p*-bromo-azobenzene-oxalacetic ester, dimethyl hydrazobenzene, azoxybenzene, and azobenzene. Unsatisfactory results were given by phenylhydrazine, benzalphenylhydrazine and formazyl compounds. In the case of *m*-ethoxy-azobenzene and *p*-bromo-azobenzene-oxalacetic ester the amounts of nitrogen found were 0.15 and 0.13 per cent. respectively too low.—W. P. S.

[Tannin Extracts] Candle Filter Method: Report of the Commission appointed to Investigate the —, as a Substitute for Filter Paper. *Collegium*, 1905, 46–49.

THE members of the International Association of Leather Trades Chemists, at their seventh conference appointed a commission, consisting of 12 members, to investigate and report upon the method proposed by J. G. Parker and E. E. M. Payne (*Collegium*, 1904, 249), of filtration of solutions for tannin analysis through a specially prepared filter candle [modified Berkefeld filter-candle].

Determinations were made upon six different tanning extracts by each member of the commission. The solutions, prepared for analysis according to the standard method of the Association, were filtered through: (1) No. 605 Schleicher and Schull filter paper; (2) the candle filter; and the filtrates evaporated to determine the percentage of total soluble matter.

The results of the various determinations made by the members of the commission are given in the report; these are in close agreement with each other. The filter candle absorbs little or no colouring matter from the liquor, and, therefore, no correction for absorption is necessary;

the filtration is most rapid, and though the initial cost of the filter is greater, the method is cheaper than when paper is employed, owing to the large number of determinations that can be performed without replenishing the filter candle.

The commission recommended that the size of the filter candle be much larger than at present, and that the exact dimensions be specified.

The Executive Committee of the Association have decided that the filter candle method be adopted as the official method for the filtration of all tannin solutions previous to analysis and that it be compulsory for use in official work from March, 1905. —M. C. L.

Acetone, Source of Error in the Determination of — by the Iodine-Meth. J. W. Vaubel and O. Schner. Z. angew. Chem., 1905, 18, 214—215.

IN Messinger's method (this J., 1889, 138) for determining acetone, the quantity of thiosulphate used in titating back is always too low. The authors recommend titating the unused iodine by arsenious acid after adding bicarbonate to the acidified solution, this course being found to yield correct results. The facts are discussed in the light of the ionic hypothesis and the demands of mass-action. —E. SPS.

XXIV.—SCIENTIFIC & TECHNICAL NOTES.

Phosphorus; Phosphorescence of —. E. Jungfleisch. Comptes rend., 1905, 140, 444—447.

WHEN an inert gas, carefully deprived of oxygen, is passed over phosphorus at the ordinary temperature, there is no sign of phosphorescence, although the gas, charged with the vapour of phosphorus, becomes just perceptibly luminous when allowed to stream into the air in a dark room. The admission of even a minute quantity of oxygen with the inert gas, however, causes the phosphorus to glow, and enormously increases the luminosity of the gas issuing into the air. Analysis shows that the issuing gas under these circumstances contains much more phosphorus than corresponds with the vapour pressure of phosphorus at the temperature of the experiment. Passage through a vessel cooled to 10° C. removes the phosphorescent substance almost completely; and an inert gas, afterwards passed through this vessel at room temperature, becomes phosphorescent. An oxide of phosphorus, then, is the active substance in phosphorescence. —J. T. D.

Radiotellurium. W. Marekwald. Ber., 1905, 38, 591—594. (See this J., 1903, 49, 1146).

WORKING on a large quantity of crude tellurium, obtained from about 15 tons of Joachimsthal pitchblende, the author succeeding in preparing about 3 mgrms. of radiotellurium, many times more active than the product prepared by him previously (*loc. cit.*). His further experiments confirm the view that radiotellurium is an individual radio-active substance, not identical with Curie's polonium. Doubtless the latter product, like Geisel's polonium, contains radiotellurium, but it is a mixture, not an individual substance. —A. S.

Aurous Oxide; Supposed Solubility of — in Water. L. Vanino. Ber., 1905, 38, 462—463.

THE author finds that the blue liquid obtained on mixing freshly-precipitated aurous oxide with water is not a solution, but a colloidal suspension. The suspended matter can be separated by shaking the liquid with barium sulphate or kieselsuhr, and allowing to settle; or by passing through a Pukall's earthenware filter. —A. S.

Gold Hydrosols. L. Vanino. Ber., 1905, 38, 463—466.

COLLOIDAL solutions of gold can be prepared from solutions of gold trichloride by the use of methyl or ethyl alcohol as a reducing agent, without the addition of alkali. The colour of the colloidal solution obtained, varies with the proportions of the gold salt and of alcohol employed. It was also found that by leading a current of hydrogen through a dilute aqueous solution of gold chloride (1.5 c.c. of a solution containing 0.43% per cent. of gold in the form

of chloride, diluted to 150 c.c.) and allowing the liquid to stand for a long time in a well-corked flask, a permanent coloration appeared. —A. S.

Albuminoids; Oxidation of — by Calcium Permanganate. II. Oxidation of Glue. F. Kutscher and A. Schenk. Ber., 1905, 38, 455—459.

By preparing larger quantities of the oxidation product of glue (gelatin), and by modifying the method previously given (this J., 1904, 1902), the authors have been enabled to separate the various substances formed and to identify them. After oxidising as before, the solution was filtered, the filtrate concentrated as much as possible on the water-bath, and allowed to stand in a cold place for 24 hours. The crystals so obtained were filtered off and washed. These crystals were then dissolved in water, the calcium removed by precipitation with ammonium carbonate, and the solution again concentrated. From this insoluble residue was obtained which was found to consist of oxamide. The mother-liquor from the latter contained ammonium oxamate.

The filtrate from the above-mentioned crystals was next evaporated to a thin syrup and precipitated with hot saturated solution of picric acid. The granular crystalline precipitate was separated by filtration after lapse of 24 hours, washed with alcohol, dried and weighed. From 250 grms. of gelatin, 20.3 grms. of picricate precipitate was obtained, and was found to consist solely of guanipicric acid. The filtrate from the latter yielded no crystalline organic bases. —W. P. S.

l-Arabinose and Xylose; Diphenylhydrazones of —. B. Tollens and A. D. Maurenbrecher. Ber., 1905, 38, 500—501.

NEUBERG has stated that the diphenylhydrazone of arabinose melts at 216°—218° C., and that the melting point given by Muther and Tollens, viz., 204°—205° C., is incorrect owing to the use of impure diphenylhydrazones. The authors have again prepared the hydrazone, special precautions having been taken in the purification of materials, with the result that the lower melting point is re-affirmed. Diphenylhydrazine has been employed for the identification of arabinose in the product of hydrolysis of cacao beans.

Xylose-diphenylhydrazone.—The authors give the melting point of this substance as 107°—108° C., whereas Neuberg has stated it to be 103°—104° C.

The authors add that they determine the melting points of hydrazones and osazones by the method described by Muther and Tollens (Ber., 1904, 37, 314). —J. F. B.

Odoriferous Substances; Consumption of — in Etiolated Plants. E. Charabot and A. Hébert. Comptes rend., 1905, 140, 455—457.

COMPARISONS were made upon basil plants during the period of flowering, from early July to late August, one set of plants being kept in the dark, the other under natural conditions. The total essential oil, and amounts of estragol and of terpenic compounds in it, were determined at the beginning and end of the period, results being, for the average plant:—

	July 4	August 26.	
		Natural.	Etiolated.
Estragol	mgrms. 10.0	mgrms. 127.1	mgrms. 9.3
Terpenic Compounds	9.5	92.8	3.0
Total Essential Oil	19.5	219.9	12.3

Thus the plant kept in the dark consumes the essential oil, and especially its terpenic constituents, odoriferous substances in the plant, then, are not entirely excretory substances which cannot be utilised; they contribute, under certain circumstances, to the formation of tissue, or to the supply of energy not furnished by light. —J. T. I.

New Books.

REPORT OF THE DEPARTMENTAL COMMITTEE APPOINTED BY THE BOARD OF AGRICULTURE AND FISHERIES TO INQUIRE INTO AND REPORT UPON THE WORKING IN GREAT BRITAIN OF THE FERTILISERS AND FEEDING STUFFS ACT, 1893, WITH COPY OF MINUTES APPOINTING THE COMMITTEE. Wyman and Sons, Ltd., Fetter Lane, London, E.C. 4; and 32, Abingdon Street, Westminster, S.W. 1. Oliver and Boyd, Edinburgh, or E. Ponsbury, 11, Grafton Street, Dublin. 1905. Price 4½d.

It contains 38 pages of subject matter, 19 of which are devoted to the Report of the Committee to the President of the Board of Agriculture and Fisheries, and 19 to the substance of the Evidence, this again being classified in three parts as follows:—(i) Administration of the Act. (ii) Inefficiency of Act. (iii) Deficiencies in Safeguards to Purchaser. (iv) Deficiencies in Safeguards to

Of 147 firms engaged in the petroleum industry at Baku, the eight principal ones obtained 314,000,000 pounds in 1904.

Poud = 36 lb, avoirdupois.

VII.—ACIDS, ALKALIS, Etc.,

SPANISH CHEMICAL TRADE.

Eng. and Mining J., Feb. 9, 1905.

Domestic production is inadequate to meet the increasing consumption of chemicals in Spain, and as a result imports are made from the United States, Great Britain, France, Germany and other near by countries. The imports in 1903 included 513 metric tons of hydrochloric, nitric and sulphuric acids, 6,505 tons sulphur, 17,545 tons caustic soda, 16,990 tons alkali carbonates, soda and ammonium salts (except sulphate and caustic soda) 3,771 tons chlorides (not including sodium chloride), 2,687 tons copper sulphate and 186,360 tons raw materials for manufacturing artificial fertilisers. Two years ago there were operating in Spain 23 sulphuric acid plants, 11 for distilling ammoniacal liquors, 20 for distilling coal tar products, 15 of carbon bisulphide, and 54 laboratories of chemical and pharmaceutical products. Since then there has been an increase in almost all manufacturing plants.

X.—METALLURGY.

MINERAL OUTPUT OF THE UNITED KINGDOM.

Bd. of Trade J., Feb. 23, 1905.

The following tables, showing the output of coal and other minerals in the United Kingdom at mines worked under the Coal and Metalliferous Mines Regulations Acts during the year 1904, with comparative figures for the preceding year, are taken from an advance proof (subject to correction) of the Mines and Quarries General Report and Statistics for 1904:—

I.—Output of Minerals under the Coal Mines Regulations Acts.

	1903.	1904.
	Tons.	Tons.
Barytes		4,450
Coal	230,324,295	232,411,784
Clay and shale other than fire-clay		
and oil shale	219,018	272,349
Fire-clay	3,066,835	3,043,045
Igneous rock	2,646	804
Iron pyrites	6,900	7,511
Ironstone	7,473,236	7,557,733
Limestone	38,514	37,569
Oil shale	2,009,602	2,333,062
Sandstone (including "Ganister")	102,540	106,999*
Total	243,243,586	245,775,315

*The quantity of ganister obtained was 94,868 tons.

II.—Output of Minerals under Metalliferous Mines Regulation Act.

	1903.	1904.
	Tons.	Tons.
Barytes	23,671	21,130
Clay and shale	112,848	115,892
Gold ore	28,600	23,203
Gypsum	176,980	195,665
Igneous rocks	90,236	94,255
Iron ore	1,603,148	1,003,855
Lead ore	26,355	26,371
Limestone	573,011	510,828
Rock salt	167,769	187,828
Sandstone	183,520	192,284†
Slate	164,278	168,278
Zinc ore	24,888	27,655
Other minerals	66,329	79,092
Total	3,243,633	3,246,336

† Including 2,663 tons of ganister.

Trade Report.

I.—GENERAL.

BRITISH INDIA: VALUATION TARIFF OF —.

The issues of the *Board of Trade Journal* for January and February 23 inclusive, contain the revised valuation fixed for various classes of goods imported into British India. The revised tariff came into effect on January 1, 1905. Copies of the *Journals* referred to are available from the Commercial Branch of the Board of Trade, 73, Basinghall Street, London, E.C., price 1d. each.

II.—TAR PRODUCTS, PETROLEUM, Etc.

PETROLEUM INDUSTRY IN BURMA.

Bd. of Trade J., Feb. 16, 1905.

The chief centres of production are Yenangyaung in Magway and Yenangyat in the Pakokku district, but the Burma Oil Company have also lately developed a new field Singu in Myingyan, while the Akyab and Kyaukpadaung districts are producing a small quantity of oil. The great expansion of the industry at the chief centres may be gauged from the fact that at Yenangyaung the Government Royalty in 1903-04 amounted to Rs. 7,37,134 as against Rs. 5,68,429 in the year preceding; the output from the field increases steadily and there is no sign of exhaustion of the supply. Yenangyat is a newer field, and about 50 blocks of about a square mile or so each, have been granted to the Burma, Rangoon, and Minbu Oil Companies, five are paying royalty at present. The output from this field has risen to 22,356,904 gallons, and the due to Government from Rs. 2,22,837 to Rs. 2,93,022. At the actual working at the Yenangyat field, the Burma Oil Company are working eight blocks, and have tested 16 others without finding oil. Royalty is being paid on one block by the Rangoon Oil Company, who are also obtaining a small amount of oil on several others. The Minbu Oil Company are working one block and are working on two more. The Burma Oil Company's new field at Singu yielded the Government a royalty of Rs. 1,532. The Company also prospected for oil in Prome without success.

PETROLEUM PRODUCTION OF BAKU.

Bd. of Trade J., Feb. 16, 1905.

The petroleum production of Baku during the last 10 years, as given in the *Moniteur des Intérêts Matériels* (Russels), is as follows:—1901, 671,200,000 pounds; 1902, 686,500,000 pounds; 1903, 595,800,000 pounds; 1904, 614,700,000 pounds.

The output from springs showed a decrease during 1904, whilst the amount obtained by pumping reached the unprecedented figure of 593,200,000 pounds.

The above figures do not in all cases represent the total production of minerals during the year. Large quantities of several important minerals such as iron ore, limestone, sandstone, slate, clay, &c., are obtained from quarries under the Quarries Act, and from other open workings, the returns from which are not yet available. The totals for coal and the ores of copper, lead, and zinc may, however, be regarded as substantially complete.

THERMITE: U.S. CUSTOMS DECISION.

Jan. 18, 1905.

The decision of the Board of General Appraisers of October 26, 1904, holding that thermite, a mixture of powdered metallic aluminium and iron oxide was dutiable at 45 per cent. *ad valorem*, under paragraph 193 of the present tariff, as an "article composed wholly or in part of aluminium," was sustained by the United States Circuit Court.—R. W. M.

XII.—FATS, FATTY OILS, Etc.

SESAME PULP: U.S. CUSTOMS DECISION.

Feb. 2, 1905.

Ground sesame pulp, containing the oil natural to the seed, is not free of duty as "sesame oil," under paragraph 626 of the Tariff Act. The Board held it to be dutiable at 20 per cent. *ad valorem* as a "manufactured article unenumerated," under Section 6.—R. W. M.

XI.—MANURES, Etc.

PHOSPHATE DEPOSITS IN TUNIS.

Bd. of Trade J., Feb. 23, 1905.

The following particulars are given of the three deposits in Tunis acquired by the Sfax-Gafsa Phosphate Co., on Jan. 5 last:—

Redief.—The deposits are said to be rich, the "extracts" containing 63–64 per cent. of tribasic phosphates. The cost of export (including royalty and export duty) is 3s. 11d. per ton.

Ain-Moulars.—The "extracts" are reported to contain 65–70 per cent. of tribasic phosphate; total cost of export is estimated at 8s. 10d., the railway rates to Soussa (the port of outlet) being heavy.

Mellauai.—The extracts from this deposit contain 60 per cent. of tribasic phosphate; the cost of export is about 3s. 7d. per ton. About 400,000 tons of phosphate were extracted from this deposit in 1904, and shipped to Europe, chiefly to the United Kingdom, France and Italy.

XVI.—SUGAR, STARCH, Etc.

DEXTRIN; WHITE —. U.S. CUSTOMS DECISION.

Goods invoiced as soluble starch or soluble potato starch were assessed for duty at 2 cents per lb. as "dextrin," under paragraph 285 of the present tariff, on the ground that they were known to commerce as white dextrine. The importers claimed them to be dutiable at 1½ cents per lb., under paragraph 285, as "starch," on the ground that they were physiologically, chemically and microscopically starches slightly modified.

The analyses of the two samples submitted were as follows:—Moisture, 9.70 and 9.78 per cent.; soluble starch 52.22 and 51.84 per cent.; dextrin, 29.27 and 28.83 per cent.; dextrose, 5.56 and 5.56 per cent.; ash, 0.45 and 0.40 per cent.

The Board held that the commercial designation was controlling, and that the evidence showed that the goods were generally known to trade as white dextrine, and affirmed the assessment of duty.—R. W. M.

XVII.—BREWING, WINES, SPIRITS, Etc.

METHYL ALCOHOL; TAXATION OF — IN FRANCE.

J. Officiel de la République Franç., through *Chem. Ind.*, 1905, 28, 89.

In accordance with Article 5, Section I. of the Law

of Dec. 16, 1897, with regard to the taxation of denatured spirit, the President of the French Republic, in an Order dated Jan. 4, 1905, has given his assent to a resolution passed on March 14, 1900, by the "Comité Consultatif des Arts et Manufactures," according to which methyl alcohol is to be regarded as unfit for consumption, and therefore free from the costs of denaturing and of taxation, if it contain at least 5 per cent. of acetone and 1 per cent. of dry distillation residue, which impart to it an unpleasant, empyreumatic odour.—A. S.

ALCOHOL: EXPORT OF —, FROM THE GERMAN CUSTOMS AREA IN 1904.

M. Student. Z. Spiritusind., 1905, 27, 52.

The exports of spirits in cask was only 30,136 (Dz.=Doppeltcentner, or 100 kilos.), as compared 232,797 dz. in 1903, and 313,502 dz. in 1902; of quantity 15,883 dz. consisted of re-exported impr spirits, so that the net export of German spirits was 14,253 dz. In the other years mentioned the re-exports were insignificant (1 dz. and 54 dz. respectively). With exception of Portugal which took 5424 dz., against 228 in 1903, the export trade with all the principal countries shows a great falling off, Great Britain having taken 5587 dz. in place of 55,786 dz., Switzerland 2980 instead of 51,012 dz., Hamburg 2867 against 11,284 the Netherlands 261 dz. instead of 22,412 dz., 26 dz. in place of 15,134 dz., and Austria-Hungary against 14,323 dz. in 1903. The exports of bottled and bottled spirits also showed a considerable decrease being only 5307 dz., against 22,973 in 1903, and 2 dz. in 1902. On the other hand the imports increased largely, being 38,700 dz. (though 38,600 dz. were destined for re-export as improved spirits), in comparison 8095 dz. in 1903, and 3415 dz. in 1902. The bulk of these imports (30,843 dz.) came from Russia, and 331 from Belgium.—C. S.

ALCOHOL TAX; FRENCH CUSTOMS DECISION.

Bd. of Trade J., Feb. 16, 1905.

Manufacturing tax on alcohol.—In accordance with Decree of February 18, 1904, the manufacturing tax on products with a base of "industrial alcohol" (see *J.*, 1902, 202) has been increased from the 1st Jan. 1905, from 80 cts. to 1 fr. 37 cts. per hectol. or pure alcohol.

XIX.—PAPER, PASTEBOARD, Etc.

PULP, PULP WOOD, AND PAPER; CANADIAN EXPORTS OF —.

U.S. Cons. Rep. No. 2179, Feb. 9, 1905.

Wood pulp is being shipped at the rate of 1000 a day from points along the Canadian Atlantic Railway and the Great Northern Railway, a connecting line running through Quebec Province. All this is being forwarded to mills in the United States. It is affirmed over 50,000 tons of wood pulp have been contracted in Canada by American paper manufacturers. This pulp is sent forward from eastern Ontario, New Brunswick and Quebec. In some instances it will represent the output of the mills up to March 1 next. The mills in the St. John district, Quebec, are foremost on the list of those that are shipping wood pulp to American mills.

The statistics for the fiscal year 1904 show that the export of wood pulp from Canada decreased, the export of the raw material (pulp wood), all of which goes to the United States, increased. The value of the export of pulp wood in 1904 was 1,758,049 dols., an increase over 1903 of 229,489 dols. or 4½ per cent. The export of pulp decreased 23 per cent., the value 2,409,074 dols., against 3,150,943 dols. in the previous year. The falling off was chiefly in the export to Great Britain, namely, from 1,129,173 dols. in 1903 to 548,720 in 1904. The value of exports to other countries from 226,002 dols. to 52,912 dols. The value of Canadian total exports of paper, however, rose from 849,519 to 1,097,212 dols., an increase of 247,693 dols. or 29 per cent. This paper went to the following countries: Great Britain, 447,672 dols.; the United States, 160,000 dols.; other countries, 486,531 dols.

XX.—FINE CHEMICALS, Etc.

HEMETHYLENETETRAMINE; U.S. CUSTOMS DECISION.

Jan. 31, 1905.

Hemethylenetetramine is dutiable at 55 cents per lb. medicinal preparation in the preparation of which it is used," under paragraph 67 of the present tariff. Evidence did not show that no alcohol had been used in the preparation.—R. W. M.

OPHINE MECONATE; U.S. CUSTOMS DECISION.

Feb. 10, 1905.

Opium meconate is dutiable at 1 dol. per oz., under paragraph 43 of the present tariff, as a "salt of opium." The claims of the importers that it was dutiable at 25 per cent. *ad valorem*, either as a "chemical salt," or as a medicinal preparation," were overruled.—R. W. M.

QUININE PREPARATIONS AND SALTS; U.S. CUSTOMS DECISION. Feb. 10, 1905.

The following salts of quinine were held to be free of duty under paragraph 647 of the present tariff act as "salts of cinchona bark," and not at 25 per cent. *ad valorem*, under paragraphs 67 or 68 as "medicinal preparations":—

Quinine glycerinophosphate, quinine borate, quinine hydrochloride, quinine dihydrochloride, quinine hydrochloride carbanide, quinine tannate, quinine sulfate, quinine hydroferrocyanide, quinine salicylate, quinine carbolate.—R. W. M.

QUININE AND ARISTOCHININE; U.S. CUSTOMS DECISION.

Feb. 10, 1905.

Quinine is dutiable at 25 per cent. *ad valorem*, under paragraph 67 of the tariff act as a "medicinal preparation." The claims of the importer that it was free of duty as an "alcohol or salt of cinchona bark," under paragraph 647 at 1 dol. per lb., as an "ether, not specially provided for," under paragraph 21, were overruled. The decision was rendered in the case of aristochinine, a carbolic ester of quinine.—R. W. M.

ALDEHYDE; U.S. CUSTOMS DECISION.

Feb. 8, 1905.

The Board of General Appraisers overruled the assessment of duty on merchandise invoiced as "Aldehyde Concentrated Ethylic," as an "alcoholic compound," under paragraph 2 of the present tariff, holding it to be a "chemical compound" and not a "medicinal preparation." It is dutiable at 25 per cent. *ad valorem*, under paragraph 3.—R. W. M.

Patent List.

21.—In these lists, [A.] means "Application for Patent," and [C.S.] means "Complete Specification Accepted."

Where a Complete Specification accompanies an Application, an asterisk is affixed. The dates given are (i) in the case of Applications for Patents, the dates of application, and (ii) in the case of Complete Specifications Accepted, those of the Official Journals in which acceptances of the Complete Specifications are advertised. Complete Specifications thus advertised as accepted are open to opposition at the Patent Office immediately, and to opposition within two months of the said dates.

—PLANT, APPARATUS, AND MACHINERY.

- [A.] 3015. Suzuki. Furnaces.* Feb. 14.
- 3105. Ray. Vacuum evaporating apparatus. Feb. 15.

Publication Committee :

The President.

Julian L. Baker.	Charles A. Kohn, M.Sc., Ph.D.
G. Bellby.	Ivan Levinstein.
J. Carter Bell.	J. Lewkowsitch, Ph.D.
Joseph Bernays, M.I.C.E.	A. R. Ling.
H. Brunner.	W. Macnab.
Edw. Divers, M.D., D.Sc., F.R.S.	N. H. Martin.
Sir John Evans, K.C.B., F.R.S.	B. E. R. Newlands.
T. Fairley.	John Pattinson.
Prof. A. G. Green.	Prof. W. J. Pope, F.R.S.
Samuel Hall.	F. B. Power, Ph.D.
John Heron.	Prof. H. R. Procter.
D. B. Hewitt, M.D.	Sir Wm. Ramsay, K.C.B., F.R.S.
Prof. W. R. E. Hodgkinson, Ph.D.	Boverton Redwood, D.Sc.
E. Grant Hooper.	Walter F. Reid.
David Howard.	John Spiller.
Julius Hübner.	W. S. Squire, Ph.D.
Prof. A. K. Huntington.	L. T. Thorne, Ph.D.
Wm. Kellner, Ph.D.	Thomas Tyrer.

COUNCIL FOR YEAR ENDING JULY 1905.

President : Wm. H. Nichols, M.S., LL.D., D.Sc.

Vice-Presidents :

Phillips Bedson.	Ivan Levinstein.
Edi Coblenz.	Max Muspratt.
Edw. Divers, F.R.S.	T. J. Parker.
R. E. Hodgkinson.	Dr. F. B. Power.
Hooper.	Sir Wm. Ramsay, K.C.B., F.R.S.
Howard.	Thos. Tyrer.

Ordinary Members of Council :

Grossmann.	B. E. R. Newlands.
Mattmann.	Prof. W. J. Pope, F.R.S.
Langway.	Dr. Boverton Redwood.
R. Lang.	Walter F. Reid.
Lewkowsitch.	Frank Scudder.
Martin.	Dr. W. S. Squire.

Sectional Chairmen and Secretaries :

Smale.	CANADIAN.	Alfred Burton.
Carey.	LIVERPOOL.	W. R. Hardwick.
Salamon.	LONDON.	Julian L. Baker.
Bell.	MANCHESTER.	Julius Hübner.
Dunn.	NEWCASTLE.	F. C. Garrett.
W. Moore.	NEW YORK.	Dr. H. Schweitzer.
Wood.	NOTTINGHAM.	S. R. Trotman.
Tomson.	SCOTTISH.	Dr. Thos. Gray.
Liversidge, F.R.S.	SYDNEY, N.S.W.	T. U. Walton.
R. Procter.	YORKSHIRE.	Thos. Fairley.

Honorary Treasurer :

Samuel Hall, East London Soap Works, Bow, E.

Honorary Foreign Secretary :

Dr. Ludwig Mond, F.R.S.

General Secretary : Charles G. Cresswell.

Palace Chambers, 9, Bridge Street, Westminster, S.W.

Telegraphic Address : 59, Palatable, London.

Editor :

Watson Smith, 34, Upper Park Road, Haverstock Hill, N.W.

Assisted by the following Staff of Abstractors :

Official Notices.

COMMUNICATIONS.

Authors of communications read before the Society, or its Local Sections, are requested to take notice that Article 43 of the Bye-laws the Society has the right of publication for three months of all such papers. Payment of this Bye-law renders papers liable to be used by the Publication Committee, or ordered to be used for the Journal, in which case no reprints can be sent to the author.

ANNUAL GENERAL MEETING, 1905.

The Annual General Meeting will be held in London on the 10th of July next, and the proceedings will commence on the 10th of July 10th. Full particulars will appear later.

INTERNATIONAL CONGRESS OF APPLIED CHEMISTRY, ROME, 1906.

A meeting of the Organising Committee of the Sixth International Congress of Applied Chemistry, held in Rome on March 2 last, Prof. E. Paternò in the chair, decided to divide the Congress into the same number of sections as was the case at Berlin in 1903. The suggestion of the Presidents of foreign Committees, and the date of meeting was fixed for April, 1906, during the week.

All communications with respect to the Congress should be addressed to the President, Prof. E. Paternò, Casaperna 89, Rome.

List of Members Elected.

March 23rd, 1905.

Prof. W. B., 42, Morris Avenue, Athens, Ohio, U.S.A., Prof. of Chemistry (Ohio University).
 Lyman M., Revere Rubber Co., Chelsea, Mass., U.S.A., Chemist.
 George A., 503, Walnut Street, Newtonville, Mass., U.S.A., Chemist.
 Gerald F., Hunter's Hill, Sydney, N.S.W., Australia, Paint Manufacturer.
 Roscoe E., 17, South 13th Street, Newark, N.J., U.S.A., Chemist.
 Dr. K. N., The Indian Pharmacy, Girgaum, Bombay, India, Manager.
 Harold W., 153, West 121st Street, New York City, U.S.A., Chemist.
 Thomas J., c/o General Chemical Co., Hegeville, Ill., U.S.A., Chemist.
 Eric, 5, Oak Terrace, Beech Street, Liverpool, England, Chemist.
 John Michael, 39, Queen Street, Melbourne, Victoria, Australia, Metallurgist and Chemical Engineer.
 Percival G. W., c/o Mr. S. Trott, 6 G., Morgan Mansions, Highbury, N., Metallurgical Chemist.
 W. Ellis, 80, Arundel Avenue, Liverpool, Sugar Refiner.
 Arthur D., 93, Broad Street, Boston, Mass., U.S.A., Consulting Chemist.
 G. D., Perranuthnoe, Marazion, Cornwall, The Owner.
 Ernest, "Yerong," Glossop Street, Balmain, Sydney, N.S.W., Australia, Paint Works Manager.

Moignot, René, 51, Westbourne Grove, Bayswater, London, W., Chemical Engineer.
 Moody, Dr. Gerald T., Lorne House, North Dulwich, S.E., Lecturer on Chemistry.
 Neff, Robert W., 22, India Square, Boston, Mass., U.S.A., Chemical Manufacturer.
 Nichols, E. Remington, 25, Broad Street, New York City, U.S.A., Treasurer (Nichols Chemical Co.).
 Oakes, Francis J., 2, West 72nd Street, New York City, U.S.A., Dye and Chemical Manufacturer.
 Ogden, Alfred W., Room 1007, 641, Washington Street, New York City, U.S.A., Chemist.
 Ormandy, W. R., Bewsey Cottage, Warrington, Chemist.
 Osborne, Frank W., Herold's Institute, Drummond Road, Bermondsey, S.E., Chemist.
 Otsuki, Prof. Chiri, Am Kleinen Felde 321, Hanover, Germany; and Imperial University of Kioto, Japan, Prof. of Applied Chemistry.
 Patton, Walter D., United States Glue Co., Milwaukee, Wis., U.S.A., Chemist.
 Potter, Chas. Ed., c/o City Dairy Co., Ltd., Spadina Crescent, Toronto, Canada, General Manager.
 Sewell, B. F. Brooke, Eden Terrace, Catonsville, Baltimore, Md., U.S.A., Chemical Engineer.
 Shainwald, Ralph L., jun., 667, Madison Avenue, New York City, U.S.A., Chemical Student.
 Speight, W. E., Sewage Works, Deighton, Huddersfield, Chemist.
 Temperley, Joseph, 22, Down Street, Piccadilly, London, W., Shipowner.
 Tichenor, Henry D., 18, Exchange Place, New York City, U.S.A., Custom House Broker.
 Van Dyk, Dr. L. A., 317, West 93rd Street, New York City, U.S.A., Chemist.
 Waddell, Montgomery, 1, West 101st Street, New York City, U.S.A., Consulting Engineer.
 Weissmüller, Ernest Chas., 8, Stanley Villas, Runcorn, Cheshire, Research Chemist.
 Widen, Peter, Foxboro', Mass., U.S.A., Leather Chemist.
 Wyrall, Cyril de, Ridgefield Park, N.J., U.S.A., Chemist.

Changes of Address.

When notifying new addresses, members are requested to write them distinctly, and state whether they are temporary or permanent. Multiplication of addresses is also to be avoided as tending to create confusion. When sending subscriptions, the use of the form attached to the application helps in the verification of addresses, on which the safe delivery of the Journal depends.

Beasley, Jno. K.; Journals to c/o The Duff Development Co., Ltd., c/o Patterson and Simmonds, Singapore, S.S.
 Burnham, J. C.; all communications to Cordite Factory, Aruvankad, Nilgiris, India.
 Connah, J., 1/o Rudall Crescent; 12, Cecilia Road, Heath Drive, Hampstead, N.W.
 Crossley (not "Crosley" as in list) Watson, 1/o Nelson, B.C.; 15, Rosebery Street, Comholme, Todmorden, Lancashire.
 Dickenson-Gair, C. J., 1/o Clapham; 55, Lyham Road, Brixton, S.W.
 Dow, A. W., 1/o Hillyer Place; 1724, Q. Street N.W., Washington, D.C., U.S.A.
 Glegg, Robt., 1/o Liverpool; Agricultural Laboratory, Marischal College, Aberdeen.
 Grimwood, Robt. G., 1/o Stroud Green; 43, Leaside Avenue, Muswell Hill, N.
 Habirshaw, W. M.; Journals to 341, Madison Avenue, New York City, U.S.A.

- Hirst, H. R., 1/o Dewsbury: Bank House, Staincliffe, Batley, Yorks.
- Kittredge, H. G., 1/o Linden Avenue: 217, North Ludlow Street, Dayton, Ohio, U.S.A.
- Lange, Dr. M.: Journals to Malapani, bei Oppeln a. Schl., Germany (temp.)
- Loomis, H. M., 1/o Norristown: Box 301, West Chester, Pa., U.S.A.

- Perkins, T. S., 1/o Easton: Spring Garden Place, Brooklyn, N.Y., U.S.A.
- Pettit, Alf., 1/o Flatbush: 3421, Glenwood Road, Brooklyn, N.Y., U.S.A.
- Platts, J. C., 1/o Heaton Moor Lodge: 13, Howard Avenue North, Heaton Chapel.
- Proctor, W. W., 1/o The Side: 184, Portland Road, Newcastle-on-Tyne.
- Rawson, C.: Journals (temp.) to c/o Badische Anilin und Soda Fabrik, Ludwigshafen a. Rhein, Germany.
- Schoder, Dr. R., 1/o Berlin: 6, Brandreth Road, Balham, S.W.
- Scott, Walter, 1/o Manchester: c/o The Powell Duffryn Steam Coal Co., Ltd., Aberaman Offices, near Aberdare.
- Thomson, Allen B., 1/o Silvertown: Furzedown, Abbey Wood, Kent.
- Thorburn, Jas., 1/o Stevenston: c/o The British Explosives Syndicate, Pitsea, Essex, Manager.
- Thurlow, N., 1/o Union Place: 78, Warburton Avenue, Yonkers, N.Y., U.S.A.
- Timmans, W. G.: Journals to c/o The Basford Chemical Co., Basford, Nottingham.
- Vinecent, Jos. A., 1/o 421: 608, Chestnut Street, Philadelphia, Pa., U.S.A.
- Vogel, J. F. L., 1/o London: Messrs. Steinbart, Vogel, and Clouet, Highfield Works, Feltham, Middlesex.
- Waterhouse, Maj.-Gen. Jas., 1/o Court Road: Hurstmead, High Street, Eltham, Kent.
- Weems, Dr. J. B., 1/o Ames, Iowa: Aspen Hall, Crewe, Va., U.S.A.

Members Omitted from List.

- O.M. Ballard, Edw. G., 7, Godstall Chambers, Chester, Alkali Works Inspector.
1891. Fraser, L. McG., 98, Commercial Road East, London, E., Chemical Engineer.
1901. Humphrey, H. C., Edgewater, N.J., U.S.A., Chemist.
1901. Sawyer, Harris E., 163, C Street, South Boston, Mass., U.S.A., Chemist.
1892. Witthaus, Dr. R. A., Cornell Medical College, First Avenue and 28th Street, New York City, U.S.A., Professor of Chemistry.

Deaths.

- Foster, Jas., 42, Herriet Street, Pollokshields, Glasgow. March 10th.
- Prescott, Dr. Albert B., Ann Arbor, Mich., U.S.A. February 24th.

Changes of Address Required

- Gray, G. O., 1/o Iron Gate, Va., U.S.A.
- Grosvenor, Wm. M.: 1/o 25, Broad Street, New York City, U.S.A.
- North, Henry A.: 1/o 649, Green Avenue, Brooklyn, N.Y., U.S.A.
- Spieler, A. J.: 1/o 543, Gifford Street, Syracuse, N.Y., U.S.A.

London Section.

Meeting held at Burlington House, on Monday, February 6th, 1905.

MR. A. GORDON SALAMON IN THE CHAIR.

ON THE FADING OF INKS AND PIGMENTS

BY JOSEPH W. LOVIBOND.

Workers in colour have long felt the want of a method of recording the colour changes which take place in their wares under different physical conditions. The object of this paper is an attempt to fill this want by establishing a system of measuring and recording colour changes as they occur.

No attempt will be made in this preliminary paper to co-relate the colour changes with the chemical composition of the substances in which they occur, nor to deal with the chemical changes of the substances whose colour is altered, nor to trace any effect of the absorbed rays may have on the substances whose colour is unaltered.

The method of measuring a colour has already been submitted to this Society, and, therefore, need not be detailed: it will be sufficient to recall the fact that the most complex colour can be quantitatively determined by means of two colour terms and one light term, the terms themselves are associated with their mutual intensities.

The examples chosen for illustration are selected being types used for specific purposes; they were chosen in the open market, and are indicated by numbers.

In all twenty-six samples (some of which are recorded in this paper), comprising water colours, trichromatic printing inks, writing inks and dyes, submitted to three conditions of exposure—a North daylight, a South daylight, and a North day in a damp atmosphere.

The samples were placed near windows and the atmosphere was obtained by means of a wet sponge under a bell glass; no attention was paid to temperature variations in these experiments, but it is an active factor in some instances, and should not be neglected in a systematic estimation.

Measurements were made at stated intervals, the results tabulated, the details of the tables furnished for making comparisons and for charting the curves.

In the charts for plotting the fading curves, the curves were divided according to the unit values of the scales, and the abscissæ represent the time intervals in which the measurements were made. The change factor is represented by a separate curve.

The nature of the colour changes varies in the pigments, each having its own characteristics: there is an increase of colour for a time after exposure, others both colour factors fade, but at different rates, or one may fade and the other increase.

The transparencies are built up with glass end corresponding in value to those used in making measurements, and when viewed in a North daylight against a standard white background, they correspond to the pigments themselves.

already stated the nature of the colour changes vary different pigments, each having its own characteristics, no being exactly alike, but they are sufficiently diverse to admit of classification into the five following divisions; examples in each division have a wide range of detail changes with certain properties in common:—

Classification of Colour Changes by Exposure.

Colours which are stable.

Colours which increase in density for a time after exposure.

Colours in which one factor increases and the other

Colours in which all the factors fade.

Colours in which temporary changes occur with a return to their normal condition of stability or rate of change.

The object of this paper is not so much a comparison of pigments as the formulation of a system for measuring their changes; no useful purpose would be gained by going in detail with the mass of tables and curves which might be fitted to this classification; it will be sufficient for my purpose to illustrate each class by means of one example.

EXAMPLE OF CLASS 1.

Green Water Colour pigment exposed to a South Light.

is green is associated with a considerable proportion of blue, both colour factors are stable for fourteen days under the conditions named, but become brighter on the thirteenth day.

EXAMPLE OF CLASS 2.

A Blue Water Colour 5a in a South Light.

is blue is associated with a small proportion of green. The blue factor increases in intensity up to the fifth day, after which a slight decrease takes place; the green factor increases slightly up to the ninth day, after which it remains constant to the end of the period.

EXAMPLE OF CLASS 3.

A Red Water Colour 7a in a Damp Atmosphere and North Light.

This red is associated with a small proportion of orange. The red factor shows a rapid fading, whilst the orange increases at a lesser rate. The fluctuations in their rates may be influenced by variations of intensity in the impinging light from day to day.

This colour, when fresh, is a slightly saddened red violet with red preponderating, which, however, fades rapidly up to the eighteenth day of exposure, when it disappears, being replaced by blue, which increases up to the thirtieth day, when what little colour is left becomes almost indistinguishable by the increased proportion of the black factor.

EXAMPLE OF CLASS 5.

A Violet Water Colour 6b in a North Light.

This colour is a red violet, red slightly preponderating, and a small proportion of the black factor. The temporary intermittent change took place on the eighth day as indicated by the break in the curves. The increase in one colour factor is frequently associated with a decrease in the other. The interruption seldom occurs on two successive days, and in the above example only once in the fourteen days of exposure, and after the disturbance the stability, or rate of change returns to its normal condition. More frequent measurements, at intervals of one hour for example, would modify the abruptness of the curve and give some information as to the time of the day in which the disturbing energy was most active, also if the chemical composition of the pigments was known, it might be possible to identify the constituents which are sensitive to this energy, and which cause the colour fluctuations in some pigments, but not in others.

The term fading seldom expresses the full nature of the changes which take place by time and exposure; in most cases there is also a change of colour which is quantitatively defined by the unit values in the tables of measurements, when fading is unaccompanied by a change of colour, the colour lines of the charted values are parallel to each other.

DISCUSSION.

Mr. J. SPILLER said he would call the author's attention to the Government Report of Dr. Russell and Sir William Abney, in conjunction with the Presidents of the Royal Academy and of the Royal Institute of Painters, and others, who worked in much the same way as Mr. Lovibond had described; with this difference, however, that these gentlemen had been washing colours on paper of the kind here specified and exposing them, watching the changes not only from day to month but also from year to year. These experiments extended over two years.

The CHAIRMAN asked by what instrument those changes were recorded.

Mr. SPILLER said they were judged by the eye, by the curves which were plotted, and by the degrees of tint. There were other interesting statements in the report; for instance, in the case of Prussian blue, the fact that this pigment, after being bleached by light, might on putting by in the dark recover to some extent its original tint. This report showed for the 39 colours experimented upon, the relative degrees of permanence and the variation of tints by exposure; the curves indicating the changes undergone as compared with the solar spectrum which was of course an exact method of comparison.

The CHAIRMAN asked if Mr. Spiller could say whether the methods indicated in the report had been and were now employed in industry, as was suggested would be the case with this method which Mr. Lovibond had explained. He took it that that was the whole gist of Mr. Lovibond's communication, that he described a method which could be applied in industry, and pointed out that the instrument with which he worked could be applied with great advantage in connection with these particular industries, which had not probably employed the methods described in the report.

Mr. SPILLER said he supposed they could be so applied, for the tintometer was only a variation of comparison with the solar spectrum which was used by Dr. Russell and his colleagues.

Mr. E. GRANT HOOPER congratulated Mr. Lovibond on bringing forward another of his most useful applications of the tintometer. As the Chairman had already suggested, the essential point of this paper was the application of an instrument capable of the exact measurement of colour in connection with the question of fading tints. Without it one could only measure the degree of fading by standard colour solutions of different strength, but with Mr. Lovibond's colour scale this was more rapidly done and was capable of being recorded as a numerical expression.

Mr. CLAYTON BEADLE said he had consulted Mr. Lovibond with the object of ascertaining if the tintometer

could not be used for recording the various tints of the class note papers, and he was much struck by the accuracy and precision with which the colours could be recorded. He was interested in what Mr. Spiller had to say reference to the work of Dr. Russell, Sir William Abney and others with regard to the effect of light on pigments and so forth. He had read these reports they were very different from the work of Mr. Lovibond who had placed in their hands an instrument by which they could carefully and accurately record extraordinary small changes in colours, such as was not possible at the time when Dr. Russell and his colleagues were under their researches; otherwise he thought they would have had a far more useful and scientific report from gentlemen. With regard to the subject of inks, the United States had made great progress both with regard to standard required in inks and papers; many of the records had become obliterated, and it was very necessary that they should have some means by which they could record very minute changes in the fading of ink. They knew was this, that after 10, 20, or 30 years, inks had changed and had become more or less obliterated, but, by the aid of Mr. Lovibond's instrument, they have a means of recording these changes in a very short time of exposure. It seemed to him that the results would have been more valuable if the samples had been exposed to a perfectly constant light, because the condition of the atmosphere, temperature, humidity, had a great deal to do with the fading of water colours apart from the actual actinic rays. The ever-changing rays of the sun made these results much more complicated than they would have been if the various pigments had been exposed under uniform conditions for a given time.

Mr. A. S. D. ARUNDEL asked Mr. Lovibond whether trichromatic inks were laid on approximately in the way which they would be used in the trade on the printing machine, or whether they were laid on with the brush.

Mr. LOVIBOND said they were immersed in one colour and laid on with the brush in the other.

Mr. ARUNDEL said, when they were trying to reproduce objects in their true colours by three colours, it was important that the colours should not fade, or, if they faded, that they should all fade in the same ratio. Probably what Sir William Abney used was the colour apparatus or else Maxwell's colour box. They were indebted to Mr. Lovibond for a practical evaluation of the instrument.

The CHAIRMAN said the last speaker had very briefly described the purport of Mr. Lovibond's paper, and understood it: it was with a view to provide information to chemists and those concerned with the industries of pigments with an instrument whereby they could rapidly register these changes and so make their observations continuously in connection with their work, understood also, and it was only fair to state it, that Mr. Lovibond only gave this paper by way of a preliminary contribution with a view to encourage observation with this instrument in the direction indicated.

Mr. J. W. LOVIBOND, in reply, said when he commenced his work he went to the spectrum for the standard, and a very short investigation showed him that there was a sufficiently constant in the spectrum for the purpose to begin with, the idea that certain of the colour rays of the prismatic spectrum were pure was not borne out by his own work, which satisfied him that they were continuous and overlapping, so that the colour of a given line from part of the spectrum, except possibly the extreme violet, was a complex beam to which colour-character was given by one or two of the preponderating rays, and the theory which adopted red, green, and violet only simple colour, and excluded yellow because it could be produced by a mixture of red and green appeared to be inconclusive. The method of demonstration appeared to be this. A slit was taken from the green slit from the red, and the mixture produced was a yellow. He never himself saw a pure yellow so precise what he saw was a dingy colour which approximated to yellow. As far as he could judge by watching the exper-

obtained by opening the slit of the green towards the w and by opening the red towards the yellow, so that he time the mixture was obtained the overlapping w of the two became the predominating ray of the are. So far as that experiment was concerned, he d upon it as fatal as a proof. Also when it is remem- ber that the opening of this slit also lets in a number of rays, the beam which was supposed to be made up o pure colours was too complex for him to deal with. her difficulty he found was this. However much he spectrum was elongated, he could not obtain a workable which was monochromatic over the whole surface e smallest gradation gave no definite point for the n to rest on—thus making comparison impossible. f found that the only way to measure a colour was to perceptible differences, however small, between the lards. By means of the regular set of standards i he used he was able to differentiate out of a beam of ght of 20 units intensity—the average diffused day- —60 million colours. How was it possible to identify f those 60 million colours in a spectrum? He was not eating the work done with the spectrum, but he only ed how it was impossible for anyone who had to deal er colour quantitatively to take the spectrum as a lard. So that he was obliged to abandon it and ulti- ly fall back on glass standards which had been co- d to physical colour constants. The colour cons- he had relied upon up to now for co-relation to the lards had been 4 ft. of distilled water, containing u mate of potash, permanganate of potash, sulphate pper, and similarly simple chemical compounds in ion. With reference to the shortness of time, he m t say that these experiments had been all done n five weeks, but shortness of time did not detract as f as he could see from the value of the records; they e extended as long as was considered desirable, s having a colour constant to fall back upon for veying the unit. The remark about the ink experi- ns in the United States applied to all the experiments i had preceded, either for inks or for pigments; it mply a measure—simply the validity of the measure- nt that he was bringing forward. The Chairman, in his rks, gave the paper its true position. Concerning bstant light it had yet to be found. There were two tions in the light which were absolutely necessary; t st be sufficiently luminous to distinguish the colours, e found anything below 16 units of light of no value er for systematic colour work, and anything above hich was a bright summer day, was also useless. In e case there was insufficient light to distinguish the ors, and in the other the colours were more or less ed by excessive light. That had been one of the ulties in dealing with the arc lights and all such se lights, they simply masked the colour they were sed to develop.

r. GRANT HOOPER said he would like to ask a question eference to the provision of some standard light by h these colours were viewed. He had himself expe- ed the difficulty to which Mr. Lovibond had inci- ally referred of having to make comparisons with a light under which circumstances no such fine dis- tion of colour was possible, as was readily observed ur more favourable conditions. He should like to e if Mr. Lovibond had evolved any method by which e could work with light of the same colour and degree, t he was in the habit of using any lamp or other ing arrangement by which they could get a satis- ry illumination under all conditions. With this e eience of the tintometer in use would be much eased.

r. LOVIBOND said the desired light had yet to be ined. He was at work on a light, but was not very bful about it at present, but he thought there was a ee of it. This uniformity of light was very important, e had only to look at the curves to see. He had no t that the fluctuations in the curves were dependent o the nature of the light, and, if so, there were some ors or forces in the daylight which influenced certain ors in a hitherto unsuspected manner. In this pre- nary paper he had not attempted to associate these

fluctuations with any given property. He even thought it possible that it might have as much to do with the medium as with the colours themselves.

M^R. A. GORDON SALAMON IN THE CHAIR.

ESTIMATION OF ARSENIC IN FUELS—A SHORTENED METHOD.

BY GEORGE MCGOWAN, PH.D., F.I.C., AND R. B. FLORIS, A.I.C.

In the final report of the Royal Commission on Arsenical Poisoning, published in 1903 (Vol. II., p. 227, Appendix 23), full details are given of the method which we adopted in estimating the arsenic present in anthracite, &c., used for malting purposes. This method gave very concordant results, but because of the necessity for eliminating iron from the arsenical solution before the latter could be "marshed," it was rather long and troublesome.

Briefly, the method consisted in igniting the finely powdered fuel in a platinum basin, according to the method of Newlands and Ling (*J. Fed. Institutes of Brewing*, 1901, 7, 314), (a) with lime, for the total arsenic, and (b) alone, for the non-volatile arsenic, the difference between the two results representing the volatile arsenic. The ignited residue was in each case dissolved in dilute hydrochloric acid, the solution filtered, the filtrate reduced with aqueous sulphurous acid, saturated with sulphuretted hydrogen and allowed to stand in a small conical flask (which was filled nearly full and closed with a cork wrapped round with filter paper) for some days. The sulphide precipitate was then filtered off and extracted with a warm solution of dilute aqueous ammonia, the extract evaporated to dryness, and the residue oxidised by nitric acid and again evaporated. This last residue was dissolved in a solution of ammonium carbonate, the ammonia evaporated off, and the solution then reduced by a little aqueous sulphurous acid, any excess of the latter being expelled by gentle warming before the solution was made up to a given volume for "marshing."

Some time ago it occurred to us that the method of F. Platten (this J., 1894, p. 324) might be applicable, and that by making use of it the above process might be materially shortened and simplified. According to Platten, when a precipitate of arsenious sulphide is boiled with pure water, the sulphide is converted quantitatively into oxide, which remains in solution. We therefore applied this in the following way:—

(1) *Testing the method with a pure dilute solution of Arsenious Acid.*

Two separate quantities of a solution of arsenious acid, each containing 0.05413 mgrm. As_2O_3 , were acidified with 10 c.c. of arsenic-free hydrochloric acid (containing 20 per cent. HCl), diluted to 100 c.c., and precipitated with sulphuretted hydrogen, the liquids being re-saturated with the gas as required. The two precipitates, a and b, were then filtered through arsenic-free asbestos in separate Gooch crucibles.

Precipitate a was treated according to our old method and one-fifth of the final solution was "marshed." This gave a mirror equal to 0.0108 mgrm. As_4O_6 , which was used as the standard.

Precipitate b, together with the asbestos, was transferred to a flask of Jena glass and boiled for three hours with 150 to 200 c.c. of glass-distilled water, the latter being renewed from time to time as it evaporated. The additions of fresh water were so arranged that at the end of the three hours only about 30 c.c. of liquid remained in the flask, when it was again filtered through asbestos in a Gooch crucible. As it was not improbable that some of the arsenic might have become oxidised to the higher oxide in the course of the boiling, a few c.c. of aqueous sulphurous acid were added to the filtrate, and the excess of

sulphur dioxide expelled by gentle warming. One-fifth of the solution was then "marshed" and gave a mirror equal to 0.0110 mgrm. As_4O_6 , taking the mirror from a as 0.0108 grm. As_4O_6 . The arsenic from the above pure dilute solution was therefore all recovered by Platten's method. The second filtration through the Gooch crucible would of course have removed any unoxidised sulphide.

It was, however, necessary to ascertain whether an equally satisfactory result would be obtained when dealing with the sulphide precipitates from solutions of the residues from the ignition of (1) coal, and (2) coal and lime, by the method of Newlands and Ling. To test this, 2.8 grms. of an impure anthracite were ignited in a platinum basin with 3 grms. of arsenic-free lime for three to four hours, *i.e.*, until all the carbon was burnt off; the resulting ash was then treated with 2 or 3 c.c. of pure dilute nitric acid (1 in 10), to decompose any sulphides, dried, and again ignited for a short time. The residue was now dissolved in 25 c.c. of arsenic-free hydrochloric acid diluted to about 70 c.c., the solution filtered and reduced with aqueous sulphurous acid, and the excess of the latter expelled by warming. Three equal portions of the solution (each consisting of three-tenths of the whole: 0.84 grm. of the original coal) were then transferred to three conical Jena flasks of about 100 c.c. capacity, acidified further in each case with 10 c.c. hydrochloric acid, and saturated with sulphuretted hydrogen (the total volume of liquid in each flask was about 70 c.c.); the solutions were subsequently re-saturated. After standing in the corked flasks for three or four days, the mixtures were filtered through separate Gooch crucibles.

Precipitate (a) was treated by our old method and two portions, each consisting of one-fourth of the final solution (= 0.21 grm. coal), were "marshed." These gave mirrors equal to 0.012 and 0.011 mgrm. As_4O_6 .

Precipitate (b), including its asbestos, was boiled for three hours with excess of water, the extract filtered and reduced with sulphurous acid, the excess of the latter being then driven off. One-fourth of the final extract (= 0.21 grm. coal) gave a mirror equal to 0.011 mgrm. As_4O_6 .

Precipitate (c) was treated in the same way as (b), excepting that the reduction with sulphurous acid was omitted. The mirror from one-fourth of this final extract (= 0.21 grm. coal) was equal to 0.011 mgrm. As_4O_6 .

These results may be shortly summarised:—

		Mirror equal to,—
Sulphide precipitates <i>a</i> , <i>b</i> and <i>c</i> , each from 0.21 grm. coal.	(a) Treated by old method (<i>loc. cit.</i>)	0.011 mgrm. As_4O_6
	(b) Boiled with water and reduced by SO_2Aq	0.012 " "
	(c) Boiled with water and reduced by SO_2Aq	0.011 " "

A preliminary set of three estimations had already been done on the same lines as the above, but in this case the second precipitate was extracted with warm dilute ammonia previous to the reduction of the solution by sulphurous acid. The object of this was to get rid of the asbestos, which caused bumping when the flask was boiled over a small Bunsen flame. It was afterwards found, however, that with a rose burner no bumping took place; hence extraction with ammonia is unnecessary. The third precipitate was boiled up with water and the solution then reduced.

This first series of experiments did not give quite such concordant results as those which have just been quoted, but possibly this may have been due to the fact that different lots of zinc had to be used for "marshing" the first two solutions and the third one.

The results may, however, be given:—

		Mirror equal to:—
Sulphide precipitates (1), (2) and (3), each from 0.24 grm. coal.	(1) Treated by old method (<i>loc. cit.</i>)	0.012 mgrm. As_4O_6
	(2) Extracted with ammonia and the solution reduced by SO_2Aq	0.013 " "
	(3) Boiled with water and reduced by SO_2Aq	0.010 " "

We should have liked to have tested this short method further upon various other samples of fuel, but time has not so far allowed of our doing so. We think, however, that the results quoted above show that the method is reliable, and we shall be glad if any one is interested in the subject cares to put it to further proof, *e.g.*, in the direction of seeing whether the presence of much copper sulphide interferes.

In conclusion, this process for the estimation of arsenic in anthracites and other fuels may be shortly summarised as follows:—

1. Sampling and grinding of the fuel.
2. Ignition (*a*) with and (*b*) without lime, according to the method of Newlands and Ling.
3. Solution of the ash in dilute hydrochloric acid and reduction with sulphurous acid.
4. Precipitation of the arsenic as trisulphide.
5. Filtration of the precipitate through a Gooch crucible lined with asbestos, and subsequent boiling-out with water.
6. "Marshing" of the aqueous extract so obtained.

DR. RUSSELL W. MOORE IN THE CHAIR.

CHEMICAL COMBINATION OF OXYGEN AND HYDROGEN UNDER ACTION OF RADIUM RAYS.

BY BERGEN DAVIS AND C. W. EDWARDS.

This paper is a preliminary account of some experiments on the synthetic action of radium radiations, and the dissociative action of radium upon certain substances has been previously observed. When radium is dissolved in water, for example, hydrogen is continually liberated.

The authors have obtained the reverse effect, *i.e.*, the association of oxygen and hydrogen into water when those gases are exposed to the radiations of radium.

The apparatus consisted of two small bulbs of equal volume, which were connected together by a capillary tube. A drop of mercury was placed in this capillary as an indicator of the rate of the action. One of the bulbs was furnished with two electrodes for the purpose of measuring the amount of ionisation produced by the radium. About 4 mgrms. of pure radium bromide were placed on a piece of platinum foil in the bulb containing the electrodes.

The two bulbs were then filled with a mixture of oxygen and hydrogen, and phosphorus pentoxide was placed in both bulbs for the purpose of absorbing the water. The radium in the one bulb caused a combination of the gases into water. The decrease of pressure in the bulb was registered by the motion of the drop of mercury in the capillary tube toward the bulb containing the radium. The rate of motion of the drop of mercury indicated a disappearance of 36×10^{-7} c.c. of gas per second.

The amount of ionisation produced in the gas by the radium was measured by an electrometer. Care was taken to have a saturation current. The presence of an electromotive force on the electrodes did not alter the rate of the chemical action. All the ions formed were driven out by this electromotive force. This indicates that the chemical combination results from the action of ionisation, and not from ionic recombination.

The rate of leak of the electrometer showed that the electrostatic units of electricity were set free in the gas per second by the radium. If Q is the total set free

and N is the number of ions produced per second, e is the charge on one ion, then

$$Q = Ne.$$

Taking the charge on one ion as 3×10^{-10} E. S., we have $Q = 7.3 \times 10^9$ free ions produced in the gas per second.

The number of molecules of gas disappearing can be deduced from the change in volume, which was 36×10^{-7} c.c. per second. Taking the number of molecules of gas per cc as 4×10^{19} , we have the number of molecules of gas disappearing per second as $n = 144 \times 10^{12}$.

Let M equal the number of molecules of water formed per second.

$= 96 \times 10^{12}$. The ratio of M to N is $\frac{M}{N} = 13100$. That

each physical ion produced in the gas by the radium were 13100 molecules of water formed.

This ratio is surprisingly large. One of us (C. W. Richards) has since found that temperature has an effect on this ratio. The ratio increases with increase of temperature. The experiments will be continued for the attainment of more accurate results. The rate of chemical combination of other gases will also be studied in the way.

These experiments were conducted at the Physical Laboratory of Columbia University, and at Trinity College, North Carolina. The authors also wish to express thanks to Mr. H. Lieber, who has kindly furnished radium for this research.

Meeting held at Nottingham on Saturday, Feb. 25th, 1905.

MR. J. T. WOOD IN THE CHAIR.

DAMAGE CAUSED BY MAGNESIA SOAPS IN BLEACHING.

BY S. R. TROTMAN.

Among the difficulties with which bleachers of lace have to contend is that of the appearance of a yellowish or brown coloration in goods which leave the works in a perfect condition and apparently free from damage. The brown discolorations may be due to several causes, among which are:—(1) Iron. (2) Over-bleaching. (3) Mildew. (4) Grease stains. (5) The use of unsuitable soaps and water.

The present note is generally concerned with the last of these causes, which, in the experience of the author, is of a more common occurrence than is supposed. It is a very common thing to put down all discolorations to iron or over-bleaching, but in my experience the facts do often support this assumption. Over-bleaching and consequent discoloration by production of oxycellulose is comparatively rare. I have tested a large number of discoloured samples, and have rarely found more oxycellulose than can be detected in a normal piece of the goods. The method which is adopted in testing for oxycellulose is to remove all starch and soluble matters by washing with water and subsequent fermentation with yeast. The goods are then distilled with hydrochloric acid, and the distillate treated with phenylhydrazine, the resulting precipitate dried and weighed. The test is, of course, required to remove all soluble substances from the surface of the material, since a great many bodies other than oxycellulose produce furfural on distillation with acid. A number of experiments have been made with a view to determining the amount of furfural which is likely to be obtained from a normally bleached curtain, the results of which tend to show that, when proper proportions are taken to prevent over-

bleaching, the quantity found is rarely less than 0.2 per cent. On the other hand, in distinctly over-bleached samples it sometimes rises as high as 1 per cent. In certain text books much stress is laid upon the behaviour of oxycellulose towards certain basic dyes as a qualitative test for oxycellulose. That is, however, in my experience totally misleading. Perhaps the best test for oxycellulose is a careful measurement of the breaking strength of the fabric, for anything more than a trace of this body causes its equivalent of destruction of cellulose and marked tendering. These tests are, of course, made with a machine specially designed for the purpose.

The class of damage to which this note refers generally appears some considerable time after the goods have left the warehouse, and often at the end of a longish voyage to a hot country, and in several cases it has been conclusively traced to the presence of a resinate of lime or magnesia. A great many of the waters which are used in bleaching operations contain notable quantities of lime and magnesia, and are not softened, or, if so, are often softened by means of soap. Now a large quantity of the soaps used in the scouring operations contain notable quantities of resin. This resin is, of course, not to be regarded as an adulterant, for its presence is well known to both buyer and seller, and for certain scouring operations it is probable that a resin soap is preferable to one containing only fatty acids; but if it is necessary or desirable to use a soap containing resin, it is of the greatest importance that no water containing more than traces of lime and magnesia should be used with them. Both lime and magnesia resinates are insoluble in water, and, when dried, gradually become distinctly brown in colour, partly owing to dehydration and partly to dissociation. The magnesia soap is distinctly darker in colour than the corresponding lime soap. When lace goods are scoured with these resin soaps and subsequently washed with hard water, considerable quantities of calcium and magnesium resinates often become precipitated in the fibres, and, although these may not be visible at first, the characteristic brown coloration is gradually produced, this being especially the case in lightly-dressed goods. It is often possible to extract weighable quantities of fatty matter from these damaged goods and to qualitatively prove that it contains resin acid. The same remarks apply to any soap which is made from a dark oil, although not to so marked an extent, and it seems advisable that the nature of a soap used for certain scouring operations should be largely determined by the quality of the available water. The following examples will illustrate these points:—A piece of lace net was boiled with a solution of a resin soap, a portion was then scoured in soft water and was seen to be perfectly white. Further portions were scoured in water containing about 50 parts per 100,000 of magnesia and lime respectively, and subsequently dried; the discoloration was here quite apparent, being also more marked in the case of the magnesia than the lime. Another set of tests was made in the same way with a soap from a dark oil, and illustrated the same points. The suitability of a soap may readily be judged by the colour of its fatty acids, and this can be quantitatively determined by means of a Lovibond's tintometer.

Although the discolorations caused by a combination of unsuitable soaps and water is chiefly seen in cotton goods, yet the same thing is by no means infrequently met with in hosiery, where it makes its appearance chiefly in uneven dyeing. A common cause of this is the composition of the lather which is used in making up hosiery, which often contains notable quantities of magnesia and lime soaps which are extremely difficult to scour out, and almost invariably cause patchiness in subsequent dyeing operations.

DISCUSSION.

Mr. S. J. PENTECOST said the bleachers in his district found trouble with hard water. In the earlier stages of boiling with caustic soda, softened water was unnecessary; but after scouring lace goods with soap, the lime and magnesia soaps formed by hard water doubtless caused inferior whites, and, in the case of goods to be afterwards

died, uneven colours. The old method of softening by boiling the water with a little soap was most unsatisfactory, as, after skimming off the lime soap which rises to the surface, there remained a very large proportion disseminated in small particles throughout the liquor. He had come across very few of the stains caused by magnesium resinate in his own experience, as he avoided resin soap for economical reasons. Mineral oil and black-lead stains more frequently troubled the lace bleacher. The former because, when apparently cleared, it frequently developed a light yellow stain after three or four weeks; while the latter could only be removed by persistent dollying or rubbing, which often caused damage. A cheap chemical process for removing blacklead (which was used to lubricate the lace machine) would be of great assistance to the lace bleacher.

Mr. T. A. GERARD said it was an accepted rule to make scouring soaps with an excess of alkali, and this was due to the fact that few people took the trouble to soften the water. Would the soda in the soap soften the water before the hardness of the water had time to combine with the soap? Many bleachers apparently used any kind of soap, and did not get stained goods. A soap was made from locomotive grease, to which was added a quantity of resin, which was very highly coloured, and he knew of

some bleachers who claimed to obtain good results from its use; this, however, he somewhat doubted.

Mr. S. R. TROTMAN, in reply, said that an important point to be remembered was, that while sodium resin were soluble in hot water they were only very sparingly so in cold, and hence in the case of goods scoured with resin soap even in the absence of hardness, if the wash was not completed with hot water, there was always a resin soap left in the fibre, which would afterwards be transformed into calcium and magnesium resins. Addition of extra alkali to the soap was really of very little use, for firstly, unless a soap were made with particular reference to each water, there would be no guarantee the alkali would be in sufficient excess to soften; secondly, the free alkali in soap was always present as carbonates in which state it was of little use in removing hard due to magnesia, and the magnesium resins, as already shown, were more objectionable than the corresponding calcium compounds. The effect with hosiery goods was not so marked as in the case of cotton, since they retain much more water, and hence dehydration was not so rapid. The stains produced by resins were, of course, at once distinguished from those produced by acids, as they caused no tendering, which both acid and alkali bleaching invariably did.

*Copper; Use of—*in Pipes and Fittings for Superheated Steam. Mech. Eng., 1904, 14, 865–866. Science Abstracts, 1905, 8, B, 119.

A BOARD OF TRADE report dealing with the failure of a copper steam-pipe at the Edinburgh Tramway Co.'s power station is discussed, and it is pointed out that the softening of copper above 400° F. (204.5° C.), and, to some extent also of copper alloys, renders these materials unsuitable for pipes and fittings for superheated steam. The results of compression tests on two pieces of gun-metal cut from the same bar, one being tested at about 400° F. (204.5° C.), and the other in the cold state, are described, showing that the metal when heated is much less resistant to pressure than when in the cold state. Pipes for superheated steam should be of wrought iron or mild steel, and the valves should be made of special alloys, preferably those containing nickel.—A. S.

Filters; Impts. in—C. Sellenscheidt, Berlin. Pat. 11,979, May 26, 1904.

THE filtering material is contained between filter-formed of grids with conical perforations, the perforations being adjacent to the filtering medium, so that when the grids are pressed together the filtering medium enters into the perforations and into recessed portions of the frame. The object is to obtain a large filtering surface combined with a strong grid to withstand the pressure and to prevent leakage round the edges of the frame. The grids are held in position in the frame by means of adjustable wedges, in order to allow the layers of filtering medium to be

different thickness so that a uniform density of the film can be easily obtained.—W. H. C.

Temperature; Process and Apparatus for Automatically Indicating Changes in—. C. Cyon. Fr. Pat. 7,042, Aug. 6, 1904.

Two spaces, of which the change in temperature is to be indicated, is connected by a tube with another space at a different temperature. The current of air which is produced in the tube will vary in speed with the variation in the difference of temperature in the two spaces. The current of air acts on a balanced damper or on a wheel of vanes or wings. The movement produced is transmitted electrically or otherwise to some form of indicator in order.—W. H. C.

Evaporating or Drying; Apparatus for —. H. Tournour. Fr. Pat. 347,074, Oct. 13, 1904.

Two vessels, one the evaporator and the other the condenser, are connected by means of pipes and valves through two cylinders provided with pistons working jointly and acting as pumps. The pistons are actuated, either by the pressure produced in the evaporator by heating the liquid in it by a steam coil, or by some form of external power acting mechanically on the pistons.

One of the pumps withdraws air or gas laden with vapour, from the evaporator, which is at a high pressure, delivers it into the condenser which is at a lower pressure. The air expands and is consequently cooled and deposits the vapour. The cooled air is aspirated from the condenser by the other pump and is compressed and consequently heated, and is injected under the action of the liquid in the evaporator. As it is hot and dry it can take up more vapour, which is thus continually carried by the air or other inert gas from the evaporator to the condenser.—W. H. C.

II.—FUEL, GAS, LIGHT.

Peat [in Coal]; Determination of —, by Eschka's Method. C. Bender. XXIII., page 293.

ENGLISH PATENTS.

Peat and Analogous Substances; Carbonisation and Drying of —. X. M. Roux, Paris, and B. W. Gonin, London. Eng. Pat. 2578, Feb. 2, 1904.

The invention relates to a special form of drying apparatus for peat in combination with an auto-carbonising oven, wherein peat is carbonised "by the heat of fire supplied by itself." Air is dried by passing it through a chamber containing lime or other material capable of absorbing moisture, when it passes through a heating chamber into the drying chamber, through which waggons laden with raw peat travel in a direction opposed to the current of hot and dry air. Subsequently some of this dried peat is carbonised in the "auto-carbonising" oven, where it burns, and the gases evolved are collected, purified, and afterwards used for providing heat for further heating already dried peat. The gases evolved in carbonising are also used to drive a motor which moves the peat waggons.—L. F. G.

Peat; Process of Consolidating —. J. O. Green, Whitewater, Wisconsin, U.S.A., and H. T. Martin, Beloit, Wisconsin, U.S.A. Eng. Pat. 6314, Mar. 15, 1904.

Peat is ground to a fine powder till the fibre is destroyed, and is then pounded in a tube or die by a suitable hammering machine with sufficient rapidity, so that the heat generated in the hammering process releases peat-tar, which acts as a binder, so that a solid mass is forced out of the die.—L. F. G.

Gas Producers. I. W. Whitworth, Chorlton-cum-Hardy. Eng. Pat. 7079, Mar. 24, 1904.

For the purpose of preventing the excessive generation of steam in a suction gas-producer, the steam generator is arranged at one side, and projects for a short distance over the top of the fire-brick lining. A horizontal outlet channel for the hot producer-gas passes through the water in the generator, the latter being provided with an air passage above the water line, and a pipe for leading the mixture of air and steam generated down to the fire-grate, which is situated within an enclosed ashpit. The grate is hinged at one side, and supported at the other by a cam or eccentric, by means of which it can be tilted so as to facilitate the removal of clinker.—H. B.

Gas Producers. H. Gerdes, Berlin. Eng. Pat. 10,344, May 5, 1904. Under Internat. Conv., May 6, 1903.

A suction gas-producer, into which the mixture of steam and air is introduced by means of an injector beneath the fire-grate, is provided with an outlet, likewise beneath the grate, whereby any superfluous steam and air, and also any superfluous gas, may escape harmlessly, in the event of the suction periods becoming irregular or ceasing altogether.—H. B.

Gas Producers. L. Wilson, Glasgow. Eng. Pat. 20,845, Sept. 28, 1904.

The gas-producer is constructed of a number of units grouped together, each unit comprising a combustion chamber the walls of which are formed of plain or water-tube boilers, for the purpose of generating steam and so far moderating the temperature in the fuel chambers, as to prevent the adhesion of clinker and minimise the destruction of the ammonia yielded by the fuel. The boilers may be traversed by vertical fire-tube outlet passages for the hot gases, or may be enclosed in a series of fire-tubes or plain flues, the latter in turn being surrounded by a series of water-tubes for superheating the steam generated. The steam from all the boilers is collected in a common steam drum above the apparatus. The boilers are constructed of corrugated metal to allow of expansion and contraction.—H. B.

Gas; Apparatus for the Manufacture of Producer—. G. Viarmé, Paris. Eng. Pat. 27,519, Dec. 16, 1904. Under Internat. Conv., Dec. 19, 1903.

SEE Fr. Pat. 337,974 of 1903; this J., 1904, 540.—T. F. B.

Incandescence Mantles for Gas and like Illuminants and Process of Manufacturing same. H. Wien and R. Mintz, Vienna. Eng. Pat. 7668, Mar. 31, 1904.

Fused quartz is drawn into filaments from which a woven mantle is then constructed. The mantle is immersed for a long time in a strong solution of thorium and cerium salts, in order that the latter may adhere to or crystallise upon the quartz fabric, or the luminous earths may be cemented to the fabric by means of dextrin or a readily fusible salt such as an alkali carbonate. The mantle may also be woven from a mixture of quartz filaments and vegetable fibres, the whole being impregnated and burned off as usual.—H. B.

Electrodes for Arc Lamps. J. T. H. Dempster, Schenectady, U.S.A. Eng. Pat. 26,915, Dec. 9, 1904. Under Internat. Conv., Dec. 10, 1903.

The electrodes are composed principally of oxides of iron and titanium, the oxide of iron being preferably reduced more or less to the metallic state. For example, a powdered mixture of magnetic oxide of iron, 160 parts; red oxide of iron, 40 parts; rutile, 15 parts; and boric acid, 1 part, is mixed with a 5 per cent. solution of glycerin, ground up, dried to the consistency of hard putty, moulded into the desired shape, dried at 200° C. and baked at 1100°—1200° C. Part of the oxide of iron may be reduced to metallic iron, either by packing the electrodes in carbon during the baking operation, or by adding graphite to the mixture from which the electrodes are made.—H. B.

Electrodes; Arc Lamp—C. P. Steinmetz, Schenectady, U.S.A. Eng. Pat. 26,916, Dec. 9, 1904. Under Internat. Conv., Dec. 10, 1903.

A small quantity, say 2 or 3 per cent., of titanium, either in the pure state, or as a compound such as the carbide or oxide, is introduced into an ordinary carbon electrode, which is employed in conjunction with a similar electrode or with one to which no titanium has been added. The titanium volatilised into the arc imparts luminosity and a white colour to it.—H. B.

Arc Lamps and Electrodes therefor. J. Hardén, Schenectady, U.S.A. Eng. Pat. 26,918, Dec. 9, 1904. Under Internat. Conv., Dec. 10, 1903.

In alternating current arc-lamps, employing moderate voltages and current strengths, there are used, for the production of a flaming arc, two electrodes, one of which is composed principally of a titanium compound, and the other principally of carbon. For example, the one electrode is prepared from a mixture of titanium carbide, 90 parts, and carbon, 10 parts, which is mixed with a suitable binder such as tar, moulded to the desired shape, and then heated first at 900° C. and finally at 1800° C. The other electrode may consist of a shell of carbon, having a core composed of a mixture of carbon and titanium carbide, to which a suitable binder, such as water-glass, has been added.—H. B.

Electrodes; Arc Light—J. Hardén, Schenectady, Eng. Pat. 26,919, Dec. 9, 1904. Under Internat. Conv., Dec. 10, 1903.

The electrodes are composed either partially or wholly of ferromanganese, containing preferably 30 to 40 parts of manganese to 70–60 parts of iron. For example, a powdered mixture of titanium carbide, 40 parts; ferromanganese, 40 parts; and carbon, 20 parts, is moistened with water and oil, moulded into pencils or the like, baked at 200–300° C., and then fired at 1200–1300° C.—H. B.

UNITED STATES PATENTS.

Gas; Retort for the Manufacture of—G. Horn, Braunschweig, Germany. U.S. Pat. 783,435, Feb. 28, 1905.

"Smelting Refractory Ores" [Calcium Carbide]. E. F. Price, Assignor to Union Carbide Co. U.S. Pat. 782,922, Feb. 21, 1905. XI A., page 281.

FRENCH PATENTS.

Briquettes; Manufacture of Combustible—F. Chaillu, Second Addition, dated Aug. 2, 1904, to Fr. Pat. 312,276 of June 29, 1901.

The claim is for mixing the combustibles, such as coal, peat, wood shavings, vegetable matters, &c., with any kind of silicate or silicic acid, or with calcined compounds of silicic acid and bases. A certain proportion of blacklead or lampblack and sodium peroxide may also be added.

—L. F. G.

Briquettes; New [Agglomerant and] Process for Manufacturing—L. Marton. Fr. Pat. 347,092, Oct. 14, 1904.

A suitable agglomerant for briquetting coal, charcoal, coke, or mineral dust, is made by heating starch or starch residues with water in a closed vessel, till solution results. The liquid is then drawn off into another vessel and mixed with some crude petroleum if desired; it is then incorporated with the briquette material, pressed into moulds, and dried. Suitable materials for the agglomerant are: maize, potatoes, rye-grass, vetch, cheap flour, and starch waste.—L. F. G.

Peat; Process for Converting Crude—into a Solid Combustible. C. Schlickeysen. Fr. Pat. 347,106, Oct. 14, 1904.

SEE Eng. Pat. 4995 of 1904; this J., 1904, 1204.—T. F. B.

Burner for Heavy Oil; Vaporising—F. Dumontie, Mme. C. Chartier née Paysant, L. H. Ninin and Mm. M. Vénitien née Leroy. Addition dated Sept. 14, 1904 to Fr. Pat. 372,5 of Mar. 31, 1904. (See Eng. Pat. 8596 of 1904; this J., 1904, 815.)

THE joints of the apparatus described in the main patent are rendered tight, in the case of the annular apparatus by arranging the joints of the exterior and interior cylinder in the same plane; and in the case of the elongate apparatus by confining the movable cover to that part which is farthest removed from the furnace. The cleaning of the closed parts of the apparatus is effected through openings which are usually closed by screw plugs.

—W. H. C.

"Gas; Bituminous Mineral"—[Carburetted Air]. Perrier. First Addition, dated Aug. 23, 1904, to Fr. Pat. 327,461, Dec. 22, 1902.

MODIFICATIONS are described in the construction details of an apparatus in which, by means of a hot-air engine, warm air is passed over petrol for the production of carburetted air. The hot-air engine, the burner which is fed by the gas produced, drives the bellows which supply the air current, and actuates the pump which feeds the saturators with petrol. Air from the bellows first enters a small gas-holder, passes thence under pressure through a coiled pipe surrounding the burner, the engine, flows next through the saturators, and finally enters a small gas-holder from which it is led to the place of consumption.—H. B.

Light, Heat, and Power from Heavy Benzols; Process and Apparatus for the Production of—P. Léota and H. Digne. Fr. Pat. 347,080, Oct. 13, 1904.

THE process consists of carburetting air with heavy benzol of sp. gr. of about 0.910. The air is drawn from the atmosphere through a valved pipe into a gasholder, which is lifted by a piston worked by water under pressure. When full, the supply of water is cut off automatically and the holder descends by its own weight, driving the air in a second gasholder which serves as a pressure equaliser.

From this second gasholder the air is forced by the weight of the holder into the carburettors. The latter are in duplicate and worked alternately, in order that when one apparatus works badly, owing to the low temperature produced by the evaporation of the benzol, can be cut out and the other used. The carburettor is a vessel the lower part of which serves to hold the benzol whilst over the surface of the latter is a horizontal perforated partition. Tubes filled with broken pumice are fixed in these holes to dry the gaseous mixture. The air is introduced by a bell-mouthed pipe with the opening covered by gauze, under the surface of the benzol. It bubbles up, and after passing through the drying tubes it is further dried by broken pumice and "calcium" contained in the upper compartment of the carburettor. A screw-shaped fan or propeller is situated in the pipe conveying the gas from the carburettor to the pressure regulator and distributing main. It rotates the current of gas, and serves to complete the mixing of air and benzol vapour.—W. H. C.

Gas free from Tar; Producer for Weak—L. Boutillier et Cie. Fr. Pat. 347,044, Sept. 1, 1904.

BITUMINOUS fuel is fed upwards, by means of a screw conveyor, on to an inclined grate, the inner end of which rests upon a transverse wall which extends right across the fuel chamber, the top of the wall being inclined upwards as to form a prolongation of the slope of the grate. The fuel, pushed up beneath the superincumbent layer of incandescent coal, partly falls back upon itself and partly pushed over the transverse wall into a chamber formed by the transverse wall, the back wall of the producer, and the horizontal fire-grate. Air and steam are admitted beneath the inclined grate, and the gases produced are drawn off beneath the horizontal grate. The tarry vapours disengaged from the fresh fuel are deposited partly on rising through the covering layer of incandescent fuel, and partly on passing down through the reducing column collected behind the transverse wall.

rbides; Manufacture of Metallic—by means of the combined Heating Effects of the Arc and Resistance. E. Lanhoff and Comp. Continent. d'Electricité. Appl. Fr. Pat. 347,090, Oct. 14, 1904. XI A., page 281.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, PETROLEUM, AND MINERAL WAXES.

benzols; Sulphur Content of Pure—C. Schwalbe. Z. Farben- u. Textil-Ind., 1905, 4, 113—119.

The author has examined a number of specimens of benzol intended for the manufacture of aniline, and also one (p. 6 in table) marked "purissimum krist. thiophen pro analysi." The results are shown in the following table:—

	Total sulphur.	Sulphur as carbon bisulphide.	Thiophen by Dumas's method.	Thiophen by difference between total sulphur and sulphur of carbon bisulphide.
	Per cent.	Per cent.	Per cent.	Per cent.
o. 1	0.036	0.022	0.038	0.039
2	0.027	0.001	0.061	0.069
3	0.030	0.021	0.073	0.047
4	0.021	0.019	0.019	0.005
5	0.060	0.011	0.171	0.127
6	0.010	0.010	—	—

has been admitted recently by Liebermann and Fleus at the nitroso reaction will only detect thiophen with certainty within 20 minutes when at least 0.12 per cent. is present. As the average proportion of thiophen is 0.26 per cent. in commercial benzols, and 0.04 per cent. in pure benzols, it is preferable to use the isatin reaction for the detection of thiophen in the latter. A method for the determination of thiophen which is perfectly trustworthy, simple, and rapid has not yet been devised.

FRENCH PATENT.

Tar, Tar Oils, and Mineral Oils; Process of Distilling—Rütgerswerke-Aet.-Ges. First Addition, dated Sept. 24, 1904, to Fr. Pat. 329,574, Feb. 20, 1903. Under International Conv., Jan. 21, 1904. (See this J., 1903, 1041.)

Is tar and mineral oils heavier than water, the greater part of the contained water floats on the top of the liquid, the remainder being either mixed with the tar, or dissolved in it. In drying these oils to avoid frothing during distillation, it is proposed to heat the upper portion of the liquid first, to remove the supernatant water, and then to continue the heating downwards; in this way it is stated that the whole of the water can be conveniently removed from the tar. This process may be carried out by having two retorts in the same setting, one for drying and the other for distilling; the furnace is situated beneath the latter, and the flues are so arranged that a part of the furnace gases pass first to an annular space round the upper part of the drying retort, and thence round the lower part of it, and are finally carried up a chimney; the other portion of the furnace gases heats the distilling retort directly, and passes into the same chimney.—T. F. B.

IV.—COLOURING MATTERS AND DYESTUFFS.

o-Aminoazo Dyestuffs; Study of the—M. Busch and E. Bergmann. Z. Farben- u. Textil-Ind., 1905, 4, 105—113.

o-AMINOAZO dyestuffs differ from the corresponding para-compounds, in that almost invariably they behave as hydrazones of quinone-imines, $\text{NH.C}_6\text{H}_4\text{N.NHR}$, rather than as normal aminoazo compounds. (See Goldschmidt and Rosell, this J., 1890, 494.) The authors find that on benzylating aminoazotoluene with benzyl chloride and sodium carbonate in alcoholic solution, benzylaminoazotoluene is formed, but this is readily transformed in presence of glacial acetic acid into the quinonoid derivative, phenyltolylidihydrotolutriazine

Goldschmidt and Rosell obtained this latter compound directly by treating *o*-aminoazotoluene with excess of benzaldehyde, but this was probably owing to the presence in the benzaldehyde of benzoic acid, which favours the transformation of benzylaminoazotoluene into the triazine. *o*-aminoazotoluene also behaves as a primary amine when treated with benzene sulphochloride in pyridine solution, the corresponding benzene sulphamide being formed. The authors conclude that *o*-aminoazo dyestuffs have a normal constitution but are very readily transformed into quinone-imine derivatives. There is a marked difference between the normal aminoazo compounds and the tautomeric heterocyclic derivatives of *o*-quinone-imino-hydrazones; the former are real dyestuffs, whereas the latter although sometimes coloured, are more or less completely devoid of dyeing properties.—A. S.

Benzylethylaniline and Benzylidine-aniline; Determination of—W. Vaubel and O. Scheuer. XXIII., page 293.

V.—PREPARING, BLEACHING, DYEING, PRINTING, AND FINISHING TEXTILES. YARNS, AND FIBRES.

Cotton Yarn (Embroidery Yarn). Bleaching.
E. Harter. *Färber-Zeit.*, 1905, 16, 49-50.

AFTER boiling out, the yarn is well washed and entered at about 30° C. into the bleaching bath (2.5-3.0 kilos. of bleaching powder for 50 kilos. of yarn). The yarn is left in this solution for one hour, with occasional turning, taken out, and, after draining, passed through a cold acid-bath (2-2.5 litres of sulphuric acid at 168° T. for 800-1000 litres of water), and then well washed. It is then treated for some time in a boiling soap bath, washed, and again passed through the cold bleaching and acid baths. After a final washing, the yarn is ready for dyeing. —A. B. S.

Mercerised Cotton: Increased Affinity of — for Dye-stuffs and Mordants. W. Schaposchnikoff and W. Minajeff. *Z. Farb-u. Textil-Ind.*, 1905, 4, 81-84. (See also this J., 1903, 903, and 1904, 604).

PIECES of mercerised and unmercerised calico were mordanted with an alkaline solution of alum, and the amount of alumina absorbed determined. As in the case of the chrome mordant, the results were not consistent.

β -Naphthol was absorbed almost equally by both fabrics, but the dyeings of Paranitriline Red were considerably more intense and fuller on the mercerised than on the unmercerised material. In the case of Immedial Blue C, a sulphur determination showed that the mercerised fabric had absorbed about 40 per cent. more dyestuff than the unmercerised; this agrees with the result previously found in direct dyeing with dyes such as

perature. The mordants used were basic ferrous sulphate, basic chromium chloride, and aluminium acetate:—

Mordant.	Strength ° B.	Ratio of fibre to metal oxide after treatment to that of fibre to metal oxide after treatment number—									
		1	2	3	4	5	6	7	8	9	10
Iron ...	30	100	51	49	49	41	60*	40	38	30	30
Chrome	20	100	29	26	25	24	18	14	15	14	14
Alumina	7.5	100	Average 2.3								

* After the fifth mordanting with iron, the silk was heated in a soap bath.

Each treatment in the iron mordant occupied one hour, in the chrome and alumina mordants, 24 hours.—T. F.

Wool Oil: Preparation of Sulphonated —.
P. Pollatschek. *XII.*, page 282.

Bleaching and Cleansing of Vegetable Fibres.—L. 1 and F. Erban, Nachod, Bohemia. Eng. Pat. 31 Feb. 12, 1901.

VEGETABLE textiles are said to be thoroughly cleaned and bleached by immersion, at ordinary temperature, in a bath containing an alkali hypochlorite and a "clarifying body." For example, for 100 kilos. of dry cotton, the bath may consist of 500 litres of sodium hypochlorite solution (containing 0.3 per cent. of available chlorine) to which has been added 10 litres of Turpentine oil or castor oil soap (containing 75-80 per cent. fatty acid). The treatment is complete in two or three hours.—T. F. B.

Mercerising, and Apparatus therefor. W. Mather,

Indigo White and Diamine Blue 3B. With Aniline Black the unmercerised material absorbs a little more than the mercerised. If the cotton be mercerised after dyeing, it becomes darker in shade; this may be partly due to the contraction.—A. B. S.

Dyeing Processes [Mordanting]: Contribution to the Knowledge of —. VIII. Repeated Mordanting with Iron, Chrome, and Alumina. P. Heermann. *Färber-Zeit.*, 1905, 16, 66-70.

THE effect of repeatedly mordanting silk with tin has already been described by the author (this J., 1903, 1344). As the result of repeated passages of silk through iron and chrome mordants, fixing and washing between each treatment, it was found that the amount of mordant (calculated as oxide) taken up by the fibre, decreased with successive passages, the decrease in the case of the chrome mordant being much more rapid than when an iron mordant was employed. With alumina mordants, the increase in the ratio of alumina to fibre was very slight and irregular with successive treatments; in fact, for practical purposes it may be neglected. The following results were obtained, using boiled-off silk, and mordants of "normal" basicity, working at the ordinary tem-

Hübner and W. J. Pope, Manchester. Eng. Pat. 61 March 16, 1904.

IN the mercerisation of delicate fabrics unable to withstand tension, such as muslins, laces, as well as yarns, of unspun cotton, the material is held in a compressed condition between sheets of wire gauze during the operations of wetting out, treating with caustic soda lye, and washing. The pressure of the wire gauze suffices to prevent or minimise contraction of the cotton fibres during mercerisation. The invention is applied in two ways. In the one the material is rolled up with wire gauze, the whole then wetted out with steam or water, impregnated with caustic soda lye and subsequently washed; the operations may be carried out in a centrifugal machine. In the other method, which is a continuous one, the material is fed between two endless bands, *e* of wire gauze which travel horizontally, holding the material between them, under pipes from which steam, caustic soda lye and washing water are forced through the gauze and material at *a*, *b* and *c*. A preliminary wetting out with steam is performed at *a*. Squeezing rollers, *d*, are provided where needed, and suction bells are fitted underneath the supply pipes for steam, caustic soda and washing water in order to remove the excess of liquor retained by the material.—A. B. S.

Dyeing Warps for Weaving, and otherwise Treating them with Liquids; Apparatus for —. R. W. Goddard, Bedford. Eng. Pat. 5247, March 3, 1904.

der to maintain a uniform sheet of yarn during the treatment, the "yarn 2" is passed over a roller 17 and rollers 18 and 19 before it enters the liquid; the roller 19 is on the same level as the surface of the liquid. (See Eng. Pat. 15,038 of 1901; this J., 1132.)—T. F. B.

Production of Blue to Blue-black Shades on —. Y. Johnson, London. From Badische Anilin und Soda Fabrik, Ludwigshafen on Rhine, Germany. g. Pat. 8288, April 11, 1904.

Dyeing Raw Cotton, Loose Wool or Silk, Rags, Mungo, Straws, Slubbings and the like; Apparatus for —. W. Kemp, Blackpool. Partly from J. F. Morley, S. Hamilton, Canada. Eng. Pat. 13,895, June 20, 1904.

A TATABLE cage, composed of two perforated cylinders, one inside the other, around a central horizontal shaft, and provided with radial divisions, extending throughout the length of the cage, and with perforated doors and a movable cover, is mounted within a dye-vessel in such a manner as to be partially immersed in the dye-liquor contained in this. The materials to be dyed, if in the loose state, are packed in this condition in compartments formed by the radial divisions; if in the form of yarns, they are spread in hank-form upon the radial divisions, which are constructed so as to fit into the compartments, and are thus placed in the latter.—E. B.

Dyeing [Dyeing, &c.] Yarn; Machines for —. J. W. Hies, Winston-Salem, N. Carolina, U.S.A. Eng. Pat. 10,084, Nov. 30, 1904.

FIG. 1

FIG. 2

FIG. 3

A STATIONARY shaft G (see figures), fixed in bearings I within a dye-vessel A, carries upon it a number of wheels H, with oblique centres, upon which a series of larger wheels F with grooved rims is journaled. A metal roller B, suitably driven, is mounted above the vessel. Upon this rests a hollow, tubular, india-rubber roller J, internally unsupported, externally supported by the roller B and by two other rollers, one K of which is carried in fixed, the other L in movable bearings, to the end that the degree of squeezing-pressure to which the yarns are subjected by the rollers B and J may be adjusted as desired. The obliquity at which the wheels F are set, causes the yarns which pass alternately partly around them and partly around the roller B gradually to travel from one end of the apparatus to the other, the revolution of the wheels F being effected by the tension exerted upon them by the yarns.

The apparatus which, it is stated, is especially useful in dyeing yarns with Indigo, enables long lengths of these, while being repeatedly immersed in dye-liquors and squeezed, to be passed in the form of "webs," and in a continuous manner through it. If desired, one of the wheels F may be omitted from the shaft G, and its place taken by a division plate A¹, for the purpose of treating the yarns with two different dye-liquors during their passage through the machine.—E. B.

Silky Finish on Textile Fabrics or Paper; Engraved Bowls or Rollers for Producing an Improved —. W. J. Pope and J. Hübner, Manchester. Eng. Pat. 4907, Feb. 29, 1904.

THE ordinary engraved or "Schreinerised" finish on textiles is obtained by impressing the fabric with a metal cylinder engraved with some hundreds of straight lines to the inch; the full lustre of the finish thus obtained is only seen when the light falls on the fabric in a particular direction, and the finish is therefore termed non-homogeneous. The inventors obtain a homogeneous finish and a new technical effect by engraving the metal cylinder with sets of concentric circles (see figure) or similar closed figures arranged concentrically, each set of figures being so small as not to be distinguishable by the naked eye.

The finish obtained by impressing the fabric with such a cylinder presents the same appearance in whichever direction it is examined, and the lustre of the finish is further enhanced by the fact that the sets of concentric figures "shimmer," or appear to move. The lines on the engraved cylinder are from 1/100 in. to 1/500 in. apart.—A. B. S.

Designs upon Flexible Fabrics; Machine for Printing — G. A. Herzog, San Francisco. U.S. Pat. 783,580, Feb. 28, 1905.

THE machine consists of a framework supporting design and transfer rollers; the former rotates in a bearing, and the latter presses by means of gravity against the former, the transfer roller being mounted on roller bearings. The colour is applied to the transfer roller by a suitable device situated beneath it. The web of fabric is fed over the design roller, and is then returned to itself by means of a curved shield; its freshly coloured surface is then brushed with a rotating "blending brush" operated by a band from the design roller.—T. F. B.

FRENCH PATENT.

Dyeing with Oxidation [aged] Black on Animal or Vegetable Fibres and Fabrics therefrom; Process of — F. Könitzer, Fr. Pat. 347,067, Oct. 8, 1904.

SEE Eng. Pat. 21,634 of 1904; this J., 1905, 85.—T. F. B.

VI.—COLOURING WOOD, PAPER, LEATHER, &c.

ENGLISH PATENT.

Linoleum, Oilcloth, and the like Materials; Machinery for Printing the Pattern on — H. C. Shaw, Helens. Eng. Pat. 7256, March 26, 1904.

THIS invention relates to machinery for printing the pattern on linoleum or other material to which is to be applied

the pigment. The colours are applied by means of shaved flat square plates, 11, 11a, &c., mounted on pins which work in cylinders 9 which radiate from a central axis 3 thus forming a rotating plate-carrier, which is supported on a travelling frame 1a above the bed, over which the web of material (5) passes. Above the frame is situated an inking frame, consisting of a set of inking plates 21, 21a, &c., mounted on a shaft 4, which is connected by gearing to the shaft of the printing carrier, so that each printing plate may be brought into the corresponding inking plate. When a coloured fluid is introduced through the flexible tube 11 the pistons 9 are driven forward, thus causing the lowest plate (11) to press upon the material, and the next one (11c) to meet the corresponding inking plate. When the whole pattern is printed upon a square piece of material, the printing plate carrier is moved along the shaft (1a) to the desired position, and the operations are repeated, and so on until the whole width of material is printed. At this stage the material is advanced the same distance upon the bed by means of a roller 8 provided with teeth, and the process repeated.—T. F. B.

VII.—ACIDS, ALKALIS, AND SALTS.

Potassium Chloride, Bromide, and Iodide; Solubility in Water. A. Meusser. Z. anorg. Chem., 1905, 44, 79—80.

The author determined the solubility of potassium chloride, bromide and iodide in water at temperatures above and below 0° C. The results are shown in the following table:—

Potassium chloride.		Potassium bromide.		Potassium iodide.	
Temperature in °C.	Grms. of salt per 100 grms. of water.	Temperature in °C.	Grms. of salt per 100 grms. of water.	Temperature in °C.	Grms. of salt per 100 grms. of water.
+ 18.5	33.3	10.5	62.1	— 1.0	122.2
11.5	31.2	10.0	60.7	— 5.0	119.8
10.0	30.8	3.5	55.5	— 4.0	117.4

Carbonate; Action of Alkali Chlorides on — Passanik. Schweiz. Ver. anal. Chem., Jan. 17, 1905; Ann. Zeit. 1905, 29, 199.

Zinc carbonate is heated with solutions of alkali chlorides, partial formation of alkali carbonate and zinc chloride occurs, as in the reaction of alkaline earth carbonates upon ammonium chloride.—J. T. D.

Sodium Acetate; Manufacture of — from Pyroligneous Acid. C. Bauer. Chem.-Zeit., 1905, 29, 181.

Addition of 20 kilos. of caustic soda to 2000 kilos. of sodium acetate liquor of 27 B° light yellow crystals are obtained, which after recrystallisation give a white sodium acetate of good commercial value, the yield being 90 per cent.—R. L.

Potassium Permanganate and Hydrochloric Acid; Reaction between — in presence of Ferric Chloride. J. Brown. Anorg. Chem., 1905, 44, 144—153.

The author has repeated Wagner's experiments (this J., 1899, 527), heating N/10-potassium permanganate solution to 50° C., for some time with N/1-hydrochloric acid with and without the addition of N/10-ferric chloride solution, then adding oxalic acid equivalent to the permanganate originally taken, and titrating with permanganate. The results showed that in all cases per-

permanganate had been reduced during the digestion; but though on the average the amount reduced was greater when ferric chloride was present, as Wagner maintained, yet the results were widely divergent, and the amounts reduced greatly in excess of those found by Wagner. Further experiments showed that when the ferric chloride formed during the digestion was removed by bubbling carbon dioxide or air through the liquid during digestion, the amounts reduced were practically constant, were much greater than in the former set of experiments, and were alike whether ferric chloride was used or not. Moreover, the amount reduced was greatly increased, even up to 30 times the amount obtained by Wagner, by increasing the amount of original permanganate, keeping other factors unchanged. Wagner's results, then, do not prove the existence of any catalytic action of ferric chloride on the reaction between permanganate and hydrochloric acid, nor do they justify the assumption that a chloroformic acid (akin to chloroplatinic acid), is formed. If they indicate any action of ferric chloride at all, it is that it has possibly some effect on the oxidation of oxalic acid by free chlorine.—J. T. D.

Perborates. J. Bruhat and H. Dubois. Comptes rend., 1905, 140, 506—509.

The solutions of the perborates have an alkaline reaction and may be regarded as equivalent to mixtures of borates with hydrogen peroxide; the active oxygen is liberated by acidifying the solution, by heat, and by a large excess of water.

A solution of perborate in presence of excess of the salt, contains only the active oxygen corresponding to the dissolved portion. Manganese dioxide, however,

decomposes the whole of the perborate present, whether dissolved or not. The same total decomposition is also brought about by catalytic organic ferments, reductases or oxydases. The solution of hydrogen peroxide produced by the action of strong sulphuric acid on the perborates decomposes spontaneously with evolution of ozone. The alkalinity of solutions of perborates does not prevent them from liberating iodine from potassium iodide: the colour of the iodine soon disappears and oxygen is evolved. Perborates convert chromic acid and molybdic acid into perchromic acid and yellow permolybdates; they yield colour reactions with titanous and vanadous acids. They readily oxidise protoxides and their salts into higher oxides, but do not always form perborates with them. Ferrous, mercurous, manganous, and lead salts yield higher oxides without formation of perborates; the salts of other metals yield perborates of an indefinite or basic composition: uranyl perborate UO_4 is, however, a yellow compound of great stability. Perborates of the alkali metals may be obtained by precipitation of mixtures of alkali borates in presence of hydrogen peroxide. The authors describe potassium biperborate, $\text{K}_2\text{B}_2\text{O}_5 \cdot 2\text{H}_2\text{O}$, ammonium perborate $\text{NH}_4\text{BO}_3 \cdot \text{H}_2\text{O}$ and sodium perborate $\text{NaBO}_3 \cdot 4\text{H}_2\text{O}$. The latter when carefully dried, gradually loses water, forming the tri-, di- and monohydrated salts. The last is very stable and definite, containing 16 per cent. of

active oxygen; its solubility is increased in presence of feeble acids, and it is readily soluble in glycerine. J. E. B.

Boron Peroxides; Alkali Salts of — and their Reaction. O. Christensen. Oversigt over Videnskaberne. Skolebøger. Forhandlinger, 1904, 6, 397. Chem.-Zeit., 1905, 29, Rep., 43.

To prepare sodium perborate, 60 grms. of boric acid are added to a solution of 40 grms. of caustic soda in 200 c.c. of water, and when completely dissolved, 120 c.c. of 30 per cent. hydrogen peroxide are carefully introduced. When, after some time, a crystalline deposit has formed, 100 c.c. of water are added and the mixture allowed to stand for 2 days; 100 grms. of the crystallised salt are thereby obtained. Sodium perborate is a strong oxidising agent and readily oxidises chromic acid to the characteristic blue perchromic acid soluble in ether. With the exception of sodium and rubidium perborates, the salts of the alkali metals in general are fairly stable, but in solution there is always partial decomposition. The decomposed compounds can, however, be regenerated by addition of hydrogen peroxide, but the salts of the potassium group usually take up more than the theoretical quantity of oxygen. This fact, the author believes, points to the existence of higher unstable perborates of the type R_2BO_5 .—B. J. S.

Centrifugal Purification [Salts]; Efficiency of —. T. W. Richards. J. Amer. Chem. Soc., 1905, 27, 104–111.

A NUMBER of experiments are described, showing the extent of purification obtained by filtration and recrystallisation on the one hand, and centrifugal separation on the other hand. The experiments were all carried out on sodium nitrate which had been crystallised from a solution containing about 2 per cent. of nitric acid. By filtration only, crystals containing about 0.5 per cent. of nitric acid were obtained. A short treatment in a centrifugal separator reduced the amount to under 0.2 per cent., whilst by a further washing with water (1 c.c. to each 10 grms. of salt) the amount of nitric acid was reduced to 0.05 per cent. By recrystallising the product and repeating the treatment, sodium nitrate containing only 0.0001 per cent. of nitric acid was obtained; it required nine recrystallisations to produce so pure a product without using centrifugal separation. The most effective and rapid method of procedure was found to be to stop the centrifugal several times, and stir the crystals with a small quantity of the washing fluid; thus, after three such treatments with water (1 c.c. to 5 grms. of salt), sodium nitrate containing only very slight traces of nitric acid was obtained. Suitable apparatus is described for applying centrifugal methods to the purification of small quantities of substances.—T. F. B.

Phosphorus; Preparation of —. M. Neumann. Z. angew. Chem., 1905, 18, 289–292.

HEMPEL (this J., 1905, 195) was unable to obtain reduction of phosphorus from metaphosphoric acid. His yield of 92.5 per cent. gives no true criterion as to the efficiency of the method described, as the phosphorus obtained was impure. The reduction of monocalcium phosphate, $H_4Ca(PO_4)_2$ by means of carbon, can never yield a really good result, since part of the phosphorus must always remain in the residue, combined with the calcium. The author, however, in experiments without the use of electric heat, has obtained yields of 80 per cent. of pure yellow phosphorus by the reduction with carbon of metaphosphoric acid from crude Belgian calcium phosphate, at a price of 1.50 to 1.60 mark per kilo, for the finished product. The temperature of reduction (650° – 850° C.) is much lower than that required for the reduction of calcium monophosphate (1000° – 1200° C.), and the cost of heat in the latter case is thus much greater. To obtain thus practically all the phosphorus from metaphosphoric acid, it is essential that the acid employed shall be dry, for if it contain moisture much of the phosphorus will be converted into hydrogen phosphide. In the author's opinion the yields obtained by the electric method of heating do not justify the increased cost; and it is pointed out that

Hempel does not give the yields of pure phosphorus obtained. An advantage claimed by Neumann in his metaphosphoric acid method, is that cheap mineral phosphates can be used instead of the comparatively dear ash, but the extraction of the phosphoric acid should be carried out so that there is but little iron or alumina, since these bases retain phosphoric acid in the residue just as lime does. Notwithstanding this, the phosphoric acid extracted from a poor Belgian phosphate containing 50 per cent. of $Ca_3(PO_4)_2$ and 6 or 7 per cent. of $FeAl_2O_4$ yielded as much as 80 per cent. of pure phosphorus. In addition, 6 to 8 per cent. of amorphous phosphorus could be recovered from the condensed water, and 3 per cent. or 4 per cent. were present as phosphoric acid. About 5 per cent. remained in the residual silico-phosphate, leaving a final deficiency of 5 per cent. lost as phosphoretted hydrogen, &c. Little diffusible phosphorus seemed to occur through the walls of the retort, but any such loss was minimised by working under a vacuum.—C. A. M.

ENGLISH PATENTS.

Nitric Oxide and Nitric Acid; Production of — from Air or other Mixture of Oxygen and Nitrogen. H. Pauling, Bismarck, Germany. Eng. Pat. 41,800, March 7, 1904.

THE essential feature of the invention consists in heating air to a very high temperature to induce the formation of nitric oxide, and then suddenly cooling the heated air to prevent loss of the nitric oxide by reversal of the reaction. In one apparatus for carrying out the reaction, air is forced through a highly-heated chamber, leaving the latter through a small outlet meets a jet of cold atomised water. Or, air heated over an electric resistance is suddenly cooled at the place of maximum heating by water-cooled tubes; or by a water-spray.—E. S.

Nitrate, Nitrite, or Sulpho-Nitrate or Nitrite of Soda, or Potash; Processes for Manufacturing —. J. Price, London. Eng. Pat. 24,297, Nov. 9, 1900.

OXYGEN and nitrogen, obtained as described in Eng. Pat. 14,213, 1903 (this J., 1904, 787), or by fractional distillation of liquid air, are stored in separate gaseous cylinders and are discharged thence under pressure, in convenient proportions, into the lower part of a series of communicating vessels, charged with solution of a basic substance, or with such substances in a dry or deliquescent condition, through or over which the gases pass. "Carrying" or "converting" agents, among which gypsum, carbon, spongy platinum, sodium sulphate and sodium bichromate, are specified, are dissolved or suspended in the solution; or, in the case of the use of carbon or the like, may form a diaphragm packing through which the gases pass upwards. The chemical combinations may be assisted by the introduction of ozone. The solutions when saturated, are drawn off and concentrated for crystallisation, or are dried, to give the different products. The nitrates obtained, particularly calcium nitrate, may be compounded with gypsum or sodium sulphate for manurial application.—E. S.

Hydrate of Aluminium; Simultaneous Preparation and Purification of —. A. J. Boulton, London. Eng. Pat. Società Romana Solfati, Rome. Eng. Pat. 3776, Feb. 1904.

ALUMINOUS minerals containing potassium, such as

te, are attacked by sulphuric acid, and the alum obtained in crystalline form. From the hot solution the alum, aluminium hydroxide is precipitated by sodium carbonate, in a condition stated to be easily filtered, and free from iron and silica, which remain in solution. From the resulting solution of potassium and sodium sulphates, the two salts may be separated by successive crystallisations. The ammonium sulphate may be decomposed by lime, for instance, to recover the ammonia for continued use. (See also Fr. Pat. 330,280 of March 16, 1903; this J., 1903, 1086.)—E. S.

Volatile Acids; Apparatus for the Recovery of — from Solutions. E. R. Hewitt, Garden City, N.Y. U.S. Pat. 3,783, Feb. 28, 1905.

An apparatus is intended for the recovery of volatile from solutions containing soluble salts. Live steam is introduced into the receptacle containing the solution, through a pipe entering the side near the bottom. The open end of the pipe is surrounded by a curved condensing chamber, whereby condensation of the steam is induced, and a rising motion is imparted to the solution. Fresh steam is introduced through an opening in the top of the receptacle rising from the upper portion of the receptacle. A spray-plate is arranged immediately below the solution, and a side tube is provided, below the spray-plate, for the exit of the volatile products.—A. S.

Process of Treating —. C. Ellis, Boston, and B. Chalmers, Dedham, Mass. U.S. Pat. 783,750, Feb. 28, 1905.

A completely hydrated lime, containing an insoluble iron oxychloride, is produced by completely hydrating lime with a dilute solution of a metallic salt capable of forming an insoluble oxychloride with the lime.—T. F. B.

Oxides; Electrolytic Production of — in Alkaline Solutions. H. Rodman, Assignor to Electric Storage Battery Co. U.S. Pat. 782,989, Feb. 21, 1905. XI A., page 281.

Gas-Separating Process. J. E. Johnson, jun., Longdale, Va. U.S. Pat. 783,045, Feb. 21, 1905.

A body of liquid air is heated to the boiling point of oxygen, and the evaporated nitrogen is withdrawn, simultaneously with rotation of the body of liquid, whereby centrifugally removing from the source of heat residual liquid rich in oxygen, cooling another portion of it, and rotating the cooled air in proximity to the rotating body of liquid air, thereby compressing, cooling, and liquefying it.—E. S.

FRENCH PATENT.

Sulphuric Anhydride; Apparatus for the Manufacture of — [by the Contact Process]. Soc. de la Fabr. de ac. Chim. de Tentelewa. First Addition, dated Oct. 4, 1904, to Fr. Pat. 321,275, of May 20, 1902. (this J., 1903, 212.)

A chamber containing the vertical contact tubes is surrounded by a chamber of greater diameter, from which is isolated by a perforated cast-iron plate, on which is placed the greater part of the contact material, immediately above which is placed a thermometer, from the readings of which the temperature is controlled. The upper part of the larger chamber is provided with a perforated plate which serves to scatter and distribute the gases which arrive, in part from an adjoining reheater,

and in part from an external source. The process, which is surrounded by a non-conducting material, is heated initially by passing through it heated air, to which the required temperature is maintained by regulation of the admission of gas and air. The sulphuric anhydride formed flows down from the contact tubes into the lower cylinder, below which it is collected.—E. S.

VIII.—GLASS, POTTERY, AND ENAMELS.

UNITED STATES PATENT.

Glass [Sheet]; Process of Making —. W. E. Heil, Marion, Ind. U.S. Pat. 782,394, Feb. 14, 1905.

MOLTEN glass is drawn through an endless elongated slot so as to form a vertical tube having flat faces limited by convex faces. To resist the inward pressure on these convex faces during the cooling, endless cords disposed longitudinally are advanced against the tube, being protected by a ribbon of non-combustible material. The tube is then cut into lengths, which are annealed, after which the convex faces are severed from the flat faces so as to leave flat sheets.—A. G. L.

FRENCH PATENTS.

Crucible for Glass for Continuous Working. F. Lang. First Addition, of Oct. 5, 1904, to Fr. Pat. 343,309, of May 19, 1904 (this J., 1904, 1090).

To the crucible previously described is added a so-called

“boot,” a cone-shaped vessel (see figure) in which the necks of the bottles made are annealed in the main furnace itself. The “boot” is supported by projections on a platform beside the vessel in which the ladle is worked. The necks of the bottles are thrust through the holes (10), (11), of the lid, whilst hot gases enter through the opening (12) at the rear.—A. G. L.

Glass in Sheets; Manufacture of — and Apparatus therefor. Window Glass Machine Co. Fr. Pat. 347,079, Oct. 13, 1904.

SEE Eng. Pat. 22,065, of 1904; this J., 1905, 29.—T. F. B.

Glass-Furnace for Gaseous Firing for the Continuous Working of Uncovered Pots and the simultaneous production of Different Kinds of Glass. A. A. Marchand. Fr. Pat. 347,122, Oct. 15, 1904.

THE invention consists essentially in combining with each furnace one or several groups of gas-producers, each group consisting of two producers worked at different rates, the pots being strongly fired during the fusion of the raw materials, and gently heated during the succeeding period of working the glass. In the furnace the pots also are divided into two groups, each of which can be connected with each producer, the heating of each being independent of that of the other. Suitable regenerators are also provided.—A. G. L.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

Portland Cement; Materials which retard the Setting of —. R. C. Carpenter. Eng. Record, 1904 50, 769—770. Science Abstracts, 1905, S. B, 132.

KNISKERN and Glass have recently investigated the

retarding action of gypsum and calcium chloride on the setting of Portland cement. In the case of gypsum the maximum retarding effect was produced by an addition of 1.5 per cent. The retarding effect disappeared when the mixture of cement and gypsum was exposed to the air, but was restored by the addition of 2.4 per cent. of slaked lime on gauging. Small additions of gypsum for the purpose of retarding setting did not diminish the ultimate strength of the cement, except when the latter was exposed to sea water. The maximum retarding effect of calcium chloride was produced by an addition of about 0.5 per cent. (rather less than 2 lb. per barrel of cement); this addition had no injurious action on the ultimate strength of the cement. It is preferable to add the calcium chloride in the form of a solution when gauging, rather than to add the dry salt during the grinding of the cement clinker. (See also *Candl.*, this J., 1889, 543; 1890, 738; 1891, 140.)—A. S.

Powdered Substances especially Sand: Evolution of Heat on Moistening — with Water, and Experiments on the Behaviour of Water below 4° C. in this respect. G. Schwalbe. *Ann. der Physik.*, 1905, 16, 32–45. *Chem. Centr.*, 1905, 1, 580–581.

THE fact that absorption of heat takes place when porous stones are moistened with water below 4° C., has been observed by many investigators, but the statements on the subject are conflicting. The cause of the alteration of temperature is the compression of the water at the surface of the solid body. At 4° C., the effect of change of temperature on the volume of water is reversed, therefore the converse should also hold good, i.e., the change of temperature due to alteration of pressure should also be reversed. Experiments were tried with silicic acid, with various kinds of sand, and with glass powder. With the last-named, no alteration of temperature was observed on moistening. In the case of silicic acid and sand, in accordance with theory, absorption of heat was observed with water below 4° C., evolution of heat with water above 4° C., and no change at all with water at 4° C. As the temperature of the water rose, the evolution of heat increased. The amount of water, which with a given quantity of a solid substance causes a maximum evolution of heat, is different for each substance. The numbers found by experiment appear to bear some relation to the fineness of grain of the material. The very fine-grained silicic acid needed the greatest quantity of water, and gave the greatest evolution of heat; the smallest numbers were obtained with sea-sand.—A. S.

ENGLISH PATENTS.

Stone; Manufacture of Artificial —. W. Glossop, Halifax, Yorks. Eng. Pat. 8504, April 13, 1904.

To give disinfecting or hygienic properties to artificial stone, concrete, cement, mortar, or other manufactured building or paving materials, a suitable disinfectant or antiseptic substance is incorporated with the ingredients at any convenient stage of the manufacture.—W. C. H.

UNITED STATES PATENT.

Bricks, Tiles, &c.; Composition for —. W. Maguire, Toronto, Canada. U.S. Pat. 782,916, Feb. 21, 1905.

THE material consists of a mixture of 25 to 40 per cent.

of magnesium chloride, 10 to 25 per cent. of calcined magnesite, about 25 per cent. each of glass and of sand. The ingredients are mixed together in a liquid or pasty state, and are allowed to harden.—R. S. H.

FRENCH PATENT.

[*Wood, Stone, &c.; Method of Impregnating.* Hüls and Co. First Addition, of Sept. 27, 1904, to Fr. Pat. 319,758, of March 19, 1902.

WOOD or other material is treated with the impregnating liquid in a closed chamber under a pressure of several atmospheres. The excess of the liquid is then drawn out and the chamber exhausted, when the expansion of air in the pores of the material drives most of the liquid out of the interior, so as to leave only the pores nearest the surface filled with the liquid. The preliminary treatment of the material with compressed air or gas, as described in the main patent, is omitted. (See Eng. Pat. 10,102 of 1902; this J., 1902, 1028).—A. G. L.

X.—METALLURGY.

Fine Ore, Flue-Dust, Downcomer-Dust, and Stores; Utilisation of — in the Blast Furnace. J. C. J. Amer. Chem. Soc., 1905, 27, 142–144.

IT is proposed to agglomerate the fine ore, &c., which accumulates at metallurgical works, by coking with bituminous coal. The process may be conveniently carried out in a "bee-hive" oven, and the product is said to be well suited for reduction, containing more than sufficient carbon for the purpose. Agglomerates made from fine ore containing 51 per cent. of iron, and times its weight of coal were found to contain iron, 60 per cent.; lime, 2.35 per cent.; magnesia, 0.30 per cent.; alumina, 2.00 per cent.; fixed carbon, 61.2 per cent.; volatile matter, 10.56 per cent.—T. F. B.

Metallic Silver; Preparation of — in Small Quantities. J. Thallwitz. *Z. physik. u. chem. Unterr.*, 1904, 224. *Chem.-Zeit.*, 1905, 29, Rep., 45.

A MIXTURE of silver chloride, charcoal, and sodium peroxide spontaneously decomposes with formation of metallic silver according to the equation:—

IN practice the theoretical quantities of charcoal and sodium peroxide are thoroughly mixed and placed in a small crucible. Finely-powdered silver chloride is sprinkled on the surface and carefully stirred in. After a few minutes, the mixture inflames, and the metallic silver is left in shining globules.—B. J. S.

Barium; Preparation of —. M. Guntz. *Ann. Chem. Phys.*, 1905, 8, 5. *Chem.-Zeit.*, 1905, 29, Rep., 45.

THE author has succeeded in obtaining pure metallic barium. A quantity of barium amalgam (3 per cent. of mercury) is heated electrically in an atmosphere of hydrogen at 40 cm. pressure, till it contains 10 per cent. of barium. The resulting product is placed in an iron vessel and gradually heated to 950° C. *in vacuo* over a mercury pump. A residue is thereby obtained containing 98 per cent. of barium, and 2 per cent. of iron and mercury. Great care must be exercised in manipulating the temperature, constant observation of the pyrometer being essential.

Metallic barium has a greyish colour somewhat like that of lead; it melts at 850° C. and boils at 1150° C. In the molten state it dissolves most metals easily, on being one of the most refractory. It is readily attacked by water and alcohol. At 600° C. it combines with hydrogen, forming a stable hydride BaH_2 , which reacts with nitrogen to form a nitride Ba_3N_2 .

On adding barium to barium chloride a monochloride BaCl is obtained, the formation of which probably explains the difficulty of electrolyzing this salt. Sodium acts in a similar manner, except that a double chloride $\text{NaCl} \cdot \text{BaCl}$ is formed. The corresponding iodine compound $\text{NaI} \cdot \text{BaI}$ yields barium amalgam when treated with mercury.—B. J. S.

Aluminium-Bronze; Special Constituent obtained on quenching — P. Breuil. *Comptes rend.*, 1905, 1, 587—590.

The author has examined a copper-aluminium alloy "Fortior," which melts at about 1010°C .— 1030°C . as a transformation point between 690°C . and 730°C . The metal was examined as cast, and also after quenching in water from temperatures of 550°C ., 650°C ., 750°C ., and 950°C . The metal as cast showed large white in a black eutectic; when chilled from 550°C . it was nearly homogeneous and granular, and the black eutectic had almost disappeared. On chilling from 750°C . a new constituent appeared in the form of tilted needles resembling martensite in character; as the temperature from which quenching took place is further raised, this martensitic constituent became predominant and ultimately the sole constituent. It increases the elastic limit, the tensile and compressive strength increased, and the elongation diminished; phenomena are closely analogous to those in the treatment of steel. The martensitic constituent being noticed by Campbell (this J., 1904, 937), who, however, has not described its cause nor its effect on the mechanical properties of the metal. It is produced by the quenching; bars of the same alloy heated then allowed to cool in air showed no sign of it. In the case of steels, many authors have shown that there is an analogy between the effects of quenching and of hammering; and in all probability this may be the case with these aluminium-copper alloys. No doubt the slow cooling prevents the change from the martensitic constituent (formed at the high temperature) at the transformation temperature, as Osmond thinks is the case with steels.—J. T. D.

Aluminium-Lead Alloys. G. Grube. *Z. anorg. Chem.*, 1905, 44, 117—130.

Aluminium and lead in various proportions were melted in a stream of hydrogen. They were found to be completely miscible in all proportions, but the melted alloy had to be continuously stirred to prevent segregation. Study of the cooling curves of these melted alloys indicated the existence of only one compound of the two, PbMg_2 . An alloy of the two metals in these proportions (80.9 per cent. of lead) crystallises as a whole. An alloy containing less lead deposits crystals of the compound or of magnesium, according as it contains more or less than 67 per cent. of lead, and ultimately as the latter composition, when it solidifies as a eutectic mixture ($2\text{Mg} + \text{PbMg}_2$ nearly). An alloy containing more than 80.9 per cent. of lead deposits the compound or lead as it contains less or more than 97 per cent. of lead, at which composition it solidifies as a eutectic ($\text{Pb}_2 + 7\text{Pb}$ nearly). The formation of the compound occurs with slight evolution of heat. The compound is brittle, with a bright steel-blue crystalline surface; a polished surface is of a glistening grey colour. It is stable in dry air, but in moist air rapidly oxidises and decomposes to a black powder. It decomposes water in the cold. The product of its reaction on moist air is a hydroxide of the formula $\text{PbO} \cdot 2\text{MgO} \cdot 3\text{H}_2\text{O}$.—J. T. D.

Ores; Process of Smelting —, in Blast Furnaces. J. E. Johnson, jun., Longdale, Va. U.S. Pat. 783,044, Feb. 21, 1905.

The fuel is fed into the top of the furnace, and falls by gravity, in the form of a solid column having fluted portions extending laterally into a surrounding body of ore, supplied from a separate channel, intimate contact between the ore and fuel being effected, so that the gases distilled from the fuel traverse the ore and assist in its reduction. A blast, containing an excess of oxygen, and approximately free from water, is supplied to the charge in regulated proportion. The heat of the furnace is utilised by passing the escaping gases through the body of the incoming ore, and maintaining them out of contact with the incoming fuel, the waste gases having a high proportion of carbon dioxide relatively to the carbon monoxide and nitrogen. The surface of the column of fuel is cooled to prevent its adhesion to the walls of the conduit.—E. S.

CORRECTION is made of two misprints in the main patent. —E. S.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

(I.)—ELECTRO-CHEMISTRY.

Ammonia; Electrolytic Oxidation of —, to Nitrite. E. Müller and F. Spitzer. *Ber.*, 1905, 38, 778—782.

In the course of work on the electrolytic reduction of nitrates to nitrites in presence of copper, the authors found themselves obliged to repeat the experiments of Traube and Biltz (this J., 1904, 987), and have obtained results differing from those recorded by the latter authors. They consider that the apparent cessation of the reaction, $\text{NH}_3 \rightarrow \text{NO}_2$, and substitution for it of the reaction $\text{NO}_2 \rightarrow \text{NO}_3$, described by Traube and Biltz, arises from the diminution of fixed alkali round the anode, for direct experiment shows that the amount of nitrate formed decreases, other things being alike, as the concentration of fixed alkali at the anode increases, and also that the

yield of nitrite under given conditions is practically independent of the concentration of the nitrite already present in the solution. The impossibility of obtaining a higher nitrite concentration than 9 per cent., and the diminution, on further electrolysis, of the nitrite, and increase of the nitrate-concentration, mentioned by Traube and Biltz, are to be ascribed solely to the change in reaction resulting from diminution of the anodic fixed alkali; by keeping up the amount of the latter, higher yields of nitrite are obtainable. Under any circumstances, however, the cost of nitrite thus prepared will probably be too great to allow of the process being used industrially.

In the authors' experiments the gases evolved during the electrolysis consisted almost entirely of nitrogen, with a little oxygen when the nitrate-concentration was high; no nitrogen oxides were observed. In neutral or very slightly alkaline solutions a certain amount of nitrogen was evolved as the result of non-electrolytic decomposition of ammonium nitrite.—J. T. D.

Ammonia. Electrolytic Oxidation of —, W. Traube. *Ber.*, 1905, 38, 828-831.

MÜLLER and Spitzer (see preceding abstract) have overlooked the fact that the paper of Biltz and the author (this J., 1904, 987) was a preliminary notice, and that the authors expressly stated that by appropriate alteration of the composition of the anode liquid at the beginning of the operation, or by addition of ammonia or fixed alkali during the process, it was to be expected that nitrite solutions would be obtainable, of higher concentration than those obtained under the conditions of the experiments described. Experiments by Schönwald under the author's direction (still in progress) have already shown that (a) an ammoniacal copper solution containing fixed alkali absorbs atmospheric oxygen much more rapidly than one without it; (b) by increasing the initial concentrations of fixed alkali and of ammonia, more concentrated solutions of nitrite can be obtained before the formation of nitrate from the nitrite begins to occur. By the electrolysis of a solution of ammonia and fixed alkali in presence of copper, containing to start with 11 per cent. of sodium nitrite, the nitrite concentration has been increased to 17 per cent.—J. T. D.

Organic Acids. Electrolysis of —, by means of Alternating Currents. A. Brochet and J. Petit. *Comptes rend.*, 1905, 140, 442-444.

The authors have electrolysed some organic acids and their salts, using alternating currents at densities up to 1 ampère per sq. cm. (At the high densities the cell was cooled by immersion in flowing water.)

Formic Acid—Solutions of the acid, 250 grms. and 10 c.c. of sulphuric acid per litre, of potassium formate 336 grms. per litre, and of barium formate, saturated,

were used. The principal reactions were the same as in the continuous current:—

The percentage yields, calculated from the hydrogen evolved, were as follows:—

Current-Density (amp. p. sq. cm.)	Temperature °C.	Formic Acid.	Potassium Formate.	Barium Formate.
1.0	70—80	46	80—90	—
0.5	50—60	10—12	30—40	—
0.25	15—20	5	10—15	—

With formic acid, a certain quantity of oxygen is formed by simultaneous decomposition of the water present. After some time the electrodes are dulled and the yield diminishes. With potassium formate, the electrodes become covered with a deposit of loosely-adhering carbonate which rapidly lessens the current. With barium formate a similar deposit forms, mixed, however, with barium carbonate. With the formates there is only an insignificant amount of oxygen evolved; and in no case any carbon monoxide observed.

Oxalic Acid.—250 grms. and 10 c.c. of sulphuric acid per litre. The reaction $\text{H}_2\text{C}_2\text{O}_4 = \text{H}_2 + 2\text{CO}_2$ occurs. The yield was about 80 per cent. of the theoretical.

Acetic Acid.—A 40 per cent. solution containing 10 per cent. of sulphuric acid. Only a slight evolution of hydrogen occurred, for the most part oxy-hydrogen mixture, the electrodes rapidly dulled, and the gas evolution ceased.—J. T.

Aldehydes; Electrolytic Oxidation of Aliphatic —

H. D. Law. *Chem. Soc. Trans.*, 1905, 87, 198—202.

The author studied the electrolytic oxidation of formic aldehyde, acetaldehyde, propaldehyde and *iso*-butaldehyde in sulphuric acid solution with platinum electrodes. The chief products were the corresponding acids, together with smaller quantities of carbon dioxide and carbon monoxide; in the cases of acetaldehyde and propaldehyde, small amounts of the corresponding saturated hydrocarbons (methane and ethane) were also produced. The different products are probably formed according to the following equations:—

The yields of acid obtained in some of the experiments are shown in the following table:—

Electrolyte.	Current in amperes.	E.M.F. in volts.	Ampère- hours.	Acid calculated in c.c. of oxygen.	Total oxygen liberated, in
370 c.c. containing 30 grms. of formaldehyde and 37 grms. of sulphuric acid	2.0	3—4	10	1579	2085
370 c.c. containing 30 grms. of acetaldehyde and 37 grms. of sulphuric acid	5.0	7.0	12.0	2308	2690
350 c.c. containing 14 grms. of propaldehyde and 35 grms. of sulphuric acid	2.0	3.5	10	1540	2085
370 c.c. of a 2 per cent. solution of <i>iso</i> -butaldehyde, containing 37 grms. of sulphuric acid	2.0	2.5	10	177	2085

ENGLISH PATENTS.

Batteries; Storage —, B. J. B. Mills, London. From T. A. Edison, Llewellyn Park, Orange, N.J. *Eng. Pat.* 25,948, Dec. 10, 1904.

The receptacle, of nickel-plated steel, is made with welded seams, and is "practically homogeneous," and there is no possibility of leakage taking place at the joints. Within this receptacle are mounted the electrodes. The positive electrodes consist of nickel hydroxide mixed with 6 to 9 per cent. of bimuth hydroxide and the negative electrodes of finely-divided iron, or an oxygen compound

of iron. The electrodes are formed of pockets of same capacity, but the nickel electrodes are arranged in pairs so that the mass of the nickel will be approximately twice that of the iron. Diamond-shaped pieces, cut from a layer of insulating material, separate the adjacent positive and negative electrodes which are placed in alkaline electrolyte. A hollow glass valve is provided for separating mechanically entrained globules from escaping gases, and the valve floats and remains as long as any liquid remains in the valve casing cover on the valve casing prevents the entrance of air and dirt, but opens to permit of the escape of gases

side. Several batteries are supported in a crate or insulated plugs on the crate engaging with integral formed on the sides of the batteries. It is advanced to pass a discharging current through the battery, electrodes being used as cathodes with the nickel receptacle as anode. Heat is developed, and the hydrogen gas, generated within the active masses of the plates, drives out the soluble impurities [referred to as "insoluble"] into the solution (electrolyte) may then be poured off, and fresh solution introduced.—B. N.

Method of Treating or Non-Conducting Materials for Electrical Purposes; Impts. in and in the Manufacture of —. Electricite, Ltd., Manchester, and S. de Pont, Levenshulme, Lancs. Eng. Pat. 3826, Feb. 16, 1904.

A mixture is prepared of cellulose, horn or bone (10 per cent.), calcium sulphate or like material (4 per cent.), copal, sandarac or similar substances (20 per cent.) dissolved in spirit, together with mica, slate, marble or other non-conducting material (17 per cent.), aniline (1 per cent.), castor oil (6 per cent.), and cellulose or collodion-cotton (20 per cent.) dissolved in a suitable solvent such as ether alcohol. The mixture is dried at 100°–120° F., powdered, heated to a temperature (240°–250° F.) sufficient to melt the lac or agglutinant material, and subjected while being heated to a pressure of 4–5 tons per cubic inch in a die mould.—A. S.

Method of Treating or Other Liquid; Extraction of —, from Mineral Substances. O. Imray, London. In Farbwerke vormals Meister, Lucius und Brüning, Höchst a/ Maine, Germany. Eng. Pat. 3795, Feb. 15, 1904.

An electro-osmotic process for the extraction of water or liquid from substances, described in Eng. Pat. of 1900 (this J., 1901, 726), is improved by allowing electric current to act at temperatures above the boiling point. Claim is made for:—Heating the substance to be treated; heating one or both the electrodes in which the substance is placed; arranging either the electrodes as one side of a space through which the liquid medium is passed; and arranging two like or unlike electrodes as sides of the space through which the heating medium is passed.—W. H. C.

Apparatus for the Purification of —, and the Generation of Ozone. J. Harris, London. Eng. Pat. 144, Aug. 22, 1904.

An apparatus for the generation of ozone consists of a set of ozonising elements formed of plates arranged in series. One plate of each pair is made of material such as asbestos, &c., of high insulating properties, and is perforated, tufts or small coils of metal gauze or the like are inserted in the perforations and connected together in a series. The other plate may be an enamelled metal sheet and act as a dielectric and pole, or may be of glass, when it acts as a dielectric only. The apparatus is arranged in one compartment of a portable casing, the latter is provided with a fan, and with a filtering chamber, through which the air is forced either before or after being ozonised.—E. S.

[Electrically] Refining and Purifying —. N. J. H. Itzmann. Eng. Pat. 26,905, Dec. 9, 1904. III A., page 288.

UNITED STATES PATENTS.

Method of Treating or Other Liquid; Extraction of —, from Mineral Substances. O. Imray, London. In Farbwerke vormals Meister, Lucius und Brüning, Höchst a/ Maine, Germany. Eng. Pat. 3795, Feb. 15, 1904.

The upper part of the furnace, which in the example is of the drum form, is practically closed by a hood which dips into the material forming the charge. The electrodes pass through the top of the hood which is water-

cooled and provided with shafts for the exit of the gases and for introducing the charge into the furnace chamber.

—R. S. H.

Furnace; Electric —. G. O. Seward, Holcombs Rock, Va., Assignor to Willson Aluminium Co., New York. U.S. Pat. 783,736, Feb. 28, 1905.

In combination with the cover of an electric furnace, having an aperture through which an electrode passes, claim is made for a separate lid fitting within the aperture and having a flange which rests on the cover, this lid forming a complete ring around the electrode and holding it in position. The lid may be provided with a passage for the circulation of cooling water.—A. S.

Ores; Smelting Refractory —. [Calcium Carbide]. E. F. Price, Niagara Falls, Assignor to Union Carbide Co., Niagara Falls. U.S. Pat. 782,922, Feb. 21, 1905.

A charge of carbon with some calcium compound is interposed as a "resistance-conductor" between superposed electrodes. The lower electrode, forming the hearth of the furnace and near which is the zone of maximum temperature, is constructed of iron. Water cooling is adopted to cool the lower electrode and retain part in the solid form, despite the intense heat near to it. Means are provided for tapping the carbide and introducing fresh raw material.—R. S. H.

Superoxides; Electrolytic Production of — in Alkaline Solutions. H. Rodman, Assignor to Electric Storage Battery Co., Philadelphia. U.S. Pat. 782,989, Feb. 21, 1905.

"SUPEROXIDES" are produced direct from metals by utilising the metal, of which the oxide is required, as anode, in an electrolytic apparatus; the metal is enclosed in a "diaphragm." The electrolyte consists of a "dilute alkaline solution containing an acid radical." The production of a superoxide of nickel by this method is especially claimed.—T. F. B.

Separating Oily Impurities from Water; [Electrical] Apparatus for —. H. T. Davis and E. Perrott, London. U.S. Pat. 783,107, Feb. 21, 1905.

An automatic arrangement is described for opening and closing the valves for supplying the oily water and a conducting fluid, to the treatment tanks. The valves are opened by electric means when the current is turned on to the tanks.—R. S. H.

FRENCH PATENTS.

Carbides; Manufacture of Metallic —, by means of the Combined Heating Effect of the Arc and Resistance. E. Lanhoffer, and Comp. Continentale d'Electricité Appliquée. Fr. Pat. 347,090, Oct. 14, 1904.

Two furnaces are used and the electrodes are connected in series, an electric arc being produced in one furnace,

and the upper electrode is slowly raised as the material becomes filled with the sticky mass of carbide. When filled, the upper electrode is slowly lowered so that its lower surface is beneath, and constantly in intimate contact with, the carbide, and the heat produced by the resistance of the carbide melts the latter, which flows out through a suitable opening near the base of the carbide. The two furnaces are engaged simultaneously, one being employed in the production of carbide by means of the arc whilst the second is melting the product previously formed. Alternative methods are described for fusing the material by a current produced from a second source; for fusing the material by the combined effect of the two sources of current; and for simultaneously producing and partially melting the carbide. —B. N.

Ozone : Apparatus for the Industrial Manufacture of
by means of Liquid Air. P. M. Ondin. Fr. Pat.
347,118, Oct. 17, 1904.

A closed cylinder (of glass or the like) narrowed to a neck above, is surmounted by a vessel containing liquid air, the bottom opening of which is plugged with, for instance, asbestos fibres, which fibres descend some distance centrally into the cylinder, and enclose the upper portion of a vertical metal rod, descending to near the bottom of the cylinder. A helix of metal wire encircles the vertical rod, the outermost portions of the turns of the helix being only a short distance from the walls of the cylinder. The wire is connected to one pole of a condenser communicating preferably with an electrical machine, giving alternating currents of high frequency. The other pole is connected to the central rod. The liquid air flows slowly down the asbestos fibres, and volatilises into the body of the cylinder, where it is acted on by the electric discharge induced within the apparatus. The cylinder is provided near its bottom with an outlet for the ozonised air produced. —E. S.

ENGLISH PATENTS.

Electrostatic Separation [Ores] ; Method and Apparatus for —. W. Fairweather, London. From C. H. Huff, Boston, Mass. Eng. Pat. 27,449, Dec. 16, 1904.

This invention relates to the method of separating or concentrating heterogeneous mixtures, such as metal-bearing ore, by the action of rapidly varied static charges

between two terminal electrodes. The material is fed from a hopper H, with the assistance of an agitator through an adjustable slit H¹ on to a rotary repelling electrode E having a conducting surface, the latter cleaned by a rotary brush C. E¹ is an oppositely charged electrode, relatively smaller than the repelling electrode, surrounded by an insulating envelope E², and mounted on blocks which are adjustable in slots E³ formed in an adjustable arm E². A divider D of insulating material, adjustable vertically and horizontally, is placed between E and E¹ so as to act as an obstruction in the trajectory of the less susceptible particles, but so that the highly susceptible particles pass in their trajectory over the divider. Rapid variations in potential may be obtained by connecting E and E¹ with the terminals of a transformer, the latter "stepping" the potential from a high-potential alternating dynamo. Several pulsations are thus given during the time required for a particle of the material to pass through the field. An alternative method is described for subjecting the material to rapid "potential variations," so as to produce shocks or electrical impacts, "between relatively long time intervals intervene." In the case of the secondary of the transformer and the electrodes E and E¹ are placed a resistance to damp oscillatory currents, a rectifier if the shocks are to be of positive or negative polarity only and a spark gap. In parallel with the electrostatic condenser and a non-inductive resistant shunt, when the potential rises, the condenser is charged until the spark gap breaks, when the electrodes E and E¹ are energised, and a field potential equal to the breakdown potential of the spark gap is created. The non-inductive resistance shunts the electrodes, and the potential of the electrodes is rapidly reduced to zero. This device excludes from the separator electrodes all potential created by the source, except a selected portion which is represented by an included fraction of the area of the normal curve. —B. N.

UNITED STATES PATENTS.

Alkali Metal Amalgam ; Method of Treating — recover the Alkali Metal. C. E. Baker and A. W. Burwell, Cleveland, Ohio. U.S. Pat. 782,893, Feb. 1905.

The alkali metal amalgam is heated in presence of hydrogen, to form an alkali metal hydride; the mercury is then distilled off, and the temperature raised sufficiently to decompose the hydride. Further claims cover the application of this process to the electrolytic production of alkali metal, by electrolyzing an alkali salt with a mercury cathode, and treating the amalgam as described. —T. B.

Metallic Sulphides ; Electrolytic Process of Reducing —. C. E. Baker and A. W. Burwell, Cleveland, Ohio. U.S. Pat. 782,894, Feb. 21, 1905.

The metallic sulphide is supported in contact with an anode in a suitable electrolytic apparatus; the sulphide is immersed in the electrolyte, which consists of an alkali chloride. The chlorine produced by the electrolysis converts the sulphide into chloride. The resulting chloride may then be melted and electrolysed in the same apparatus. —T. B.

XII.—FATTY OILS, FATS, WAXES, AND SOAP.

Wool Oil ; Preparation of Sulphonated —. P. Latschek. Chem. Rev. Fett- u. Harz-Ind., 1904, 12, 48—49.

ONE of the earliest substitutes for oleic acid as a lubricant

l was Turkey red oil, and eventually, as this was too dear by itself, it was used in admixture with linseed oil. In order to increase the emulsifying power of the product, these oils are now also sulphonated, usually with the addition of a definite proportion of sulphuric acid, some of which is subsequently neutralised. According to the author's experiments, however, it is essential to add the necessary amount of sulphuric acid in each separate case, since otherwise the sulphonated products become too sticky. Thus assuming that castor oil, for example, required 20 per cent. of sulphuric acid, just should be added in separate portions and the mixture tested with water after each addition. As soon as an emulsion is produced, no further addition should be made, but the oil shaken and allowed to stand for 24 hours when it is again tested. If an emulsion is not still formed the sulphonation is repeated with an additional amount of acid. Finally, the product is washed with a solution of sodium chloride, and a final test is made of its emulsifying power. In this way it was found that different samples of castor oil required from 15 to 25 per cent. of sulphuric acid, whilst with cotton-seed oil the amount was smaller, and with other oils such as olive oil, the amount was still smaller. The production of stickiness in the wool was found to be greatest with those sulphonated products which were made from distilled olein, and this the author attributed to the presence of unsaponifiable matter.—C. (1.)—PIGMENTS, PAINTS.

ENGLISH PATENT.

"Vegetable Black"; *Manufacture of* —, C. H. Davey, Woodford, Essex. Eng. Pat., 29,441, Dec. 30, 1904.

CRESOTE or other oil is burned in an ignition chamber furnished with a water-jacket, and the fumes are passed into a settling chamber, formed of a number of superposed floors communicating with each other at one end, each floor being divided by a partition into two lateral compartments which communicate at the end away from that at which the different floors are connected. The water-jacket serves to regulate the temperature of the ignition chamber, and to prevent "overburning"; the steam produced can be utilised for driving machinery.

Rosin; Producing — [from Pine Wood]. G. P. Craig-hill, Assignor to C. E. Heald and E. Williams, Lynchburg, Va. U.S. Pat. 783,367, Feb. 21, 1905.

PINE wood is immersed in hot or cold alcohol, and the solution is distilled to remove the alcohol and turpentine. The residue is stated to consist of "commercially pure rosin."—T. F. B.

Varnish; Process of Making — G. Tüschel, Odessa, Russia. U.S. Pat. 783,393, Feb. 21, 1905.

"RED aceroide resin" is boiled with water, and the residue melted with gum mastic, sandarac, Manila copal, and Venice turpentine; the product is dissolved in methylated spirit and mixed with a small quantity of ether.

—T. F. B.

(C.)—INDIA-RUBBER, &c.

Caoutchouc; *Chemistry of* ——. R. Ditmar. Chem.-Zeit, 1905, 29, 175.

SOME time ago (see this J., 1904, 794) the author drew attention to the red coloration produced by the action of concentrated sulphuric acid upon caoutchouc and the different fractions obtained by the destructive distillation of caoutchouc. He has since applied Riban's terpene reaction with an antimony trichloride bead (*Ann. chim. phys.* 1875, 6, 38) to caoutchouc and caoutchouc distillates. Isoprene, the fraction distilling between 70° C. and 150° C., and the dipentene, heptene, diterpene and poly-

terpene fractions give instantaneously the typical red coloration. With a solution of polyprene in chloroform the bead remains colourless until it is heated, when it also turns red. The author explains this by a transformation into terpenes, and concludes that caoutchouc is an intermediate product between aliphatic and aromatic terpenes.

The author tried also to settle the dispute regarding the solubility of caoutchouc in ether (this J., 1901, 1103). He extracted finely divided Para rubber in consecutive operations with acetone, ethyl acetate, and ether. From the last extract he was able to isolate some pure caoutchouc which he identified as such by analysis, by the formation of Harries' "nitrosite" (this J., 1902, 1404, and 1903, 875), and of the dinitro acid (this J., 1904, 794), and by the reactions with antimony trichloride and sulphuric acid. Besides, rubber is precipitated from the ethyl acetate solution by alcohol, but not by ether. Caoutchouc is thus, at least, partially soluble in ether. The insolubility of caoutchouc in ether cannot be taken as a proof for the pre-existence of caoutchouc in latex, and it is not permissible to assume similar chemical composition in different latices.—R. L.

Rubber Waste: Process for Regenerating Vulcanised —. A. Kittel, Vienna. Eng. Pat. 15,436, July 11, 1904.

SEE FR. Pat. 344,731 of 1904; this J., 1904, 1126.—T. F. B.

XIV.—TANNING, LEATHER, GLUE, SIZE.

Tanning by means of Hydrodynamic Pressure: Possibility of —. E. Nihoul. Chem. Zeit., 1905, 29, 219.

REFERENCE is made to a recent article by de Marneffe, in which a method of tanning by the aid of hydraulic pressure is compared with the usual process (compare Fr. Pat. 339,428 of 1904, next column). The author has examined specimens of leather tanned by the pressure process. A strip taken from the back portion of an ox-hide, which had been tanned in 60 hours with a very weak oak extract ("1" on the barkometer," sp. gr. 1.001), showed a tensile breaking stress of 500 kilos. per sq. cm. Two strips from the same specimen of leather gave the following results when subjected to chemical analysis (see this J., 1898, 164; 1901, 1223):—

	Shoulder Piece.	Back Piece.
	Per Cent.	Per Cent.
Water	12.50	—
Ash	0.93	—
Fatty matter	0.09	—
Total soluble matter	9.68	—
Leather substance	78.20	78.21
Nitrogen	9.09	9.19
Hide substance	51.08	51.64
Combined tannin	27.89	26.89
Yield of leather	195.7	193.7
Index of tannage	53.05	51.5
Sp. gr.	0.841	—
Absorbed water (percentage on normal leather)	49.54	—

Tests upon specimens of leather prepared by the pressure process in a primitive laboratory apparatus, and in a tannery with oak, pine, quebracho, valonia and myrabolans extracts, also gave satisfactory results, and the author concludes that so far as the quality of the leather produced is concerned, the pressure process is worthy of consideration.—A. S.

Glue: Method of Treating Bones for the Production of —. E. R. Hewitt, Garden City, N.Y. U.S. Pat. 783,781, Feb. 28, 1905.

THE bones are treated with successive quantities of combined sulphurous acid and water, from which the combination has previously been dissipated," the acid being removed after each treatment, before the bone dissolved therein precipitate, and before the temperature rises above 74° F.—A. S.

FRENCH PATENTS.

Tannage of Skins; Process and Apparatus for Rapid —. H. de Marneffe. Fr. Pat. 342, Jan. 8, 1904. Under Internat. Conv., Nov. 2, Dec. 7, 1903 (see first abstract under XIV.).

THE skins are stretched on frames so as to form box-like vessels, which are disposed inside a closed chamber containing the tanning or other liquor. The liquor is then forced by pressure or by aspiration through the stretched skins, whereby a rapid tannage is effected. In the apparatus shown, the interior of the box-like vessels formed by the skins, are in communication with the outer air, whilst the tanning liquor closed chamber is maintained under any desired pressure.—A. S.

Vegetable Tanning; Process of Rapid —. M. Bonnet. First Addition, dated Sept. 10, 1904, to Fr. Pat. 342, April 25, 1904. (See this J., 1904, 943.)

THE common salt recommended in the main patent is replaced by potassium nitrate (20 kilos.) and the inorganic acid by a volatile organic acid, formic or chloroacetic acid (2 kilos.) in 100 litres water.—M. C. L.

Hides and Skins; Process of Tanning —. C. Aubert and J. Aubert. Fr. Pat. 347,097, Oct. 14, 1904.

THE prepared pelts are submitted to a three to four hours immersion in a solution of rosin soap, containing 5 to 10 per cent. of rosin with 1 to 3 per cent. of "soda"; they are afterwards placed in a 6 to 12 per cent. solution of chromic acid, iron, copper, zinc, or aluminium (preferably aluminium sulphate) for three to four hours.—M. C. L.

XV.—MANURES, Etc.

Copper Solutions; Absorption of Dilute — by C. Yokote. Bied. Centr., 1905, 34, 103—106; Arch. Hyg., 50, 193.

WHEN copper solutions are filtered through soil, the absorption is more or less completely absorbed, unless the soil is acid. Absorption also takes place in pure quartz sand, being slight at first, but increasing as the surface of sand grains becomes covered with copper oxide. The absorption in quartz sand amounted to "39.8 kilos of copper per cubic meter" without the full limit of absorption power being reached. The presence of small amounts of alkaline earthy carbonates renders the absorptive power of sand and soil very complete.

The results show that there is no danger of wells contaminated with copper when the latter is present in the water of a river in the neighbourhood. On the other hand, irrigation of fields and gardens with water containing copper is to be avoided.—N. H. J. M.

VI.—SUGAR, STARCH, GUM, Etc.

Transformation of Amylocellulose into ——. E. Loux. *Comptes rend.*, 1905, 140, 440–442.

Transformation of amylocellulose from starch-paste is a reversible reaction between 0° C. and 150° C. At lower temperature, in presence of excess of water, amylocellulose liquefies, then undergoes a degradation, successive steps of which result in a more simple form, coloured blue by iodine. The various products of the reaction, provided it has not gone too far, are obtained by a reversal of the process, of reproducing amylocellulose. The ultimate products, not capable of further action, are amyloextrin, amorphous dextrin, binary dextrose.

Complete degradation of amylocellulose the author has produced artificial starches, showing, under the microscopical structures similar to those of natural starch, giving a blue colour with iodine, but not gelling with hot water, and dissolving without residue in water. These artificial starches must themselves be regarded as complex mixtures, still containing amylocellulose. They are identical with the starches obtained from binary cereals under similar conditions of temperature; and all of them, natural and artificial, as well as amylocellulose, differ chemically only by being more or less condensed forms of the same fundamental nucleus. —J., 1904, 124, 197, 261.—J. T. D.

Works; Purification of Waste Waters of ——. A. Heide. *Z. Ver. Deutsch. Zucker Ind.* 1905, 55, 173.

Recognised that the Proskowetz system of purification of the waste waters from sugar works, except in so far as it depends on mere earth filtration, owes its efficacy to the decomposition of organic matters by fermentation whereby they are rendered precipitable. Laboratory experiments were carried out by Hermann and Ahlers on waters artificially prepared by addition of beetroot press juice to water which was subjected to fermentation with yeast at 27° C., to fermentation at 32° C., and to butyric fermentation at 40° C., with or without the addition of chalk. Purification with lime the purification effected was very near the estimation of the oxygen absorption and the amount of nitrogen. The results encourage a continuance of the process; the conditions to be observed are that the temperature should be maintained as long as possible at a temperature sufficiently high to favour fermentation should not be allowed to proceed in an acid solution, the presence of an excess of calcium carbonate in the form of powdered chalk or "separation lime."

Cleansing Composition and Process of Making ——. C. A. Spreekels and C. A. Kern, New York,

Assignors to Federal Sugar Refining Co., Jersey City, U.S. Pat. 783,150, Feb. 21, 1905.

SACCHARINE solutions are cleansed and refined by treatment with a mixture of kerosene oil with a sulphonated derivative of a fatty body. The latter is obtained by the action of concentrated sulphuric acid upon cotton-seed oil at a low temperature. (See also this J., 1902, 715 and 784.)—J. F. B.

FRENCH PATENT.

Massécuite; Continuous Apparatus for Filtering and Washing ——. H. Roy. First Addition, dated Oct. 12, 1904, to Fr. Pat. 343,194, May 16, 1904.

THE apparatus described in the original patent (this J., 1904, 1037) can be adapted for re-melting the washed sugar contained in each of the separate compartments by admitting hot water or clarifying syrup to the top one and maintaining the temperature by means of steam coils; syrups will thus be obtained from each of the other compartments in a decreasing order of purity. —J. F. B.

XVII.—BREWING, WINES, SPIRITS, Etc.

Barley; Causes of Improvement of Germinative Capacity of — by Drying or Storing. W. Windisch. *Woch. f. Brau.* 1905, 22, 89–92.

THE author has sought for an explanation of the fact that freshly harvested barley, especially if ripened and harvested in wet weather, is much inferior in germinative capacity to the same barley after kiln-drying or storage for a few weeks. Hotter has attributed the improvement which is effected by drying or storing the barley to the formation of diastatic enzymes, which he regards as essential to germination and which he thought were deficient in the fresh grain. But the author, although he has observed a distinct increase in the diastatic and proteolytic powers of the barley during after-maturation or drying, has also found that in most cases there is quite a distinct quantity of enzymes in the freshly harvested barley. Experiments are described, which were carried out upon a barley which showed a germinative energy of 33 per cent. in the fresh state and 95 per cent. after kiln-drying. In these experiments the embryos together with the scutella were separated from the endosperms and were tested as to germinative power upon artificial media composed of starch-gelatin. From determinations made with fresh and dried embryos and by re-combining fresh embryos with dried endosperms and *vice-versa*, the author concludes that the improvement effected by drying the barley is mainly or exclusively due to modifications effected, not in the endosperm, but in the embryo or the adjacent scutellum and perhaps the epithelial layer. The primary condition for germination, in the author's view, is that the cell membranes and protoplasmic layers surrounding the embryo be in such a state that the pre-formed sugars can readily penetrate by osmosis. In freshly harvested barley the membranes are either not at all or only partially permeable; they are possibly not in the state of true celluloses or are still clogged with colloidal gelatinous albumin. Drying would then condense and dehydrate the celluloses and albumins and make the walls permeable to the nutrients of the grain.—J. F. B.

Maize Malt. W. Christek. *Z. Spiritusind.* 1905, 28, 80.

MALTED maize, though very rarely used in distillery practice, is still employed to some extent in pressed yeast factories. The maize is steeped in water at 22° C. for three days, with daily changes and aeration. It remains 7–8 days on the floor at a temperature between 22° C. and 30° C. with moderate sprinkling. The rootlets are grown to 5–8 times the diameter of the corn, the acrospires to three-quarters the diameter. The fresh green malt has a bad odour, due probably to the decomposition of the maize oil. The malt kilns very easily, it requires 12 hours' withering and 10 hours' kilning

at 56°—62°. The dressing is preferably completed immediately after kilning and the total loss of weight in the malting process is 15–18 per cent.; the malt loses the unpleasant odour on kilning and acquires a sweet smell. Unlike other malts, maize malt need not be stored for more than two or three weeks after kilning before it is fit for use.

The author employed mashies prepared from barley malt (20 per cent.), maize malt (20 per cent.), wheat (30 per cent.), and maize (30 per cent.). The effect of the maize malt was to increase the quantity of froth and to intensify the "working" of the yeast, giving a strong after-fermentation, the attenuation being increased by 0.5 Bg. The yield from such a mash was 14.5 kilos. of pressed yeast and "30.3 litres per cent." of alcohol per 100 kilos. of grain. The quality of the yeast produced was very satisfactory, but copious washing was necessary to eliminate the sweetish aroma of the malted maize.—J. F. B.

Malt, Red Uncured — H. Will. Z. ges. Brauw., 1905, 28, 128—131.

A SAMPLE of injured malt, from Bohemian barley, was found to be spotted with reddish patches on the husk and rootlets, the contents of the corns being soft and milky. The cause was traced to an infection by budding fungi of the red yeast type derived from the brewery reservoir, accompanied by a cessation of the germinating process the bacterial flora of the yeast and water having prepared the way for the action of the red yeast. The cured malt exhibited numerous instances of burst and peeled husk, causing the sprouts to drop off; this was also traced to the action of bacteria softening the contents of the corns and enabling them to retain an unusual amount of moisture which, converted into steam on the kiln, caused the bursting of the husks. The cured malt was very aromatic and tender, but poor in active diastase.—C. S.

Malt: Absolute Yield of Extract and Fine Grist Analysis of — C. Bleisch and P. Regensburger. Z. ges. Brauw., 1905, 28, 124—126.

TO DETERMINE the percentage of extract left behind in the grains by the ordinary laboratory method of mashing fine grist, the grains were carefully washed until the washing ceased to give any reaction with Fehling solution, and were then dried and ground, 10 grms. of the fine meal being taken for analysis. This quantity was mashed with 100 c.c. of water, boiled for 15 minutes, cooled to 45° C., and treated with 25 grms. of a freshly prepared green malt extract (about 4 per cent. Ball's); this being found more active than commercial diastase. The further treatment was of the usual kind. The results obtained from 15 samples of malt by this method showed a fluctuation of 0.54—1.16 per cent. of unrecovered extract, the loss being apparently independent of the fineness of the original grist, which contained 81.0—82.1 per cent. of fine meal. This seems to be confirmed by the circumstance that in one case observed in practice, the proportion of unrecovered extract in the grains was less with a grist containing only 40 per cent. of fine meal than with a laboratory grist containing about 85 per cent., the more efficient extraction in the former case being possibly due to the influence of the time factor and the sparging heat.

TWO of the extreme samples were tested for their pentosan content, in order to ascertain whether the unrecovered extract in the husks was capable of unfavourably affecting the flavour of the beer. Weight for weight of extract, that from the husks contains about six times as much pentosan as that from the malt; but in practice this excess is distributed through a large volume of wort, and therefore corresponds to only a small percentage. With regard to the recovery of extract from the grains, it was found in one brewery that no improvement in this respect could be effected by increasing the proportion of fine meal in the grist from 35 to 75 per cent. Possibly, better results could be obtained by separating the hard tips of the malt corns from the husks and treating them apart.—C. S.

Malts: Albumin and Extract Percentages of this — O. Neumann. Woch. f. Brau., 1905, 2

AT THE beginning of the malting season 1904—stated that the new malts yielded on an average 0.5 to 1 per cent. less extract than those of the season, in spite of the fact that the 1904 barleys distinctly better quality than those of the previous year, being extremely pale in colour, and having very germinative power, low moisture, and on the lower percentage of albumin. Later results have confirmed the impression as to the inferiority of the new and the averages of over 100 analyses to date show according to the percentages of albumin, the 1904 extract are fully up to the values for the previous year. The earlier inferiority is attributable to the different weather experienced in the summers of 1903 and 1904. The malting of 1904 barley was begun with grain containing 3—5 per cent. less moisture than the previous crop, the time of steeping was therefore prolonged, and this, combined with a much higher temperature, led to oversteeping. The grain thus remained wet on the couches before raking over, got hot and continued to germinate. The consequent early appearance of the green mould also caused the premature removal of the grain from the floor in many cases. When these faults were recognized, however, the malts subsequently prepared have been extremely good.—J. F. B.

Top-fermentation Beer Worts [German]; Boiling under Pressure. Mumme. Woch. f. Brau., 1905, 28, 98—99. (Compare this J., 1905, 145.)

BEERS from worts boiled under pressure differ in flavour and aroma from those brewed in the ordinary manner; the pressure-boil appears to eliminate the "top-fermentation" aroma, and provided the beer is too sparingly hopped, it is comparable with a full dark lager beer. The procedure adopted by the author for top-fermentation worts brewed from cool-growing barley at 87–50° C., is as follows: The main wort is brewed under pressure for one hour, reckoning from the time when a pressure of 15 lb. per sq. in. is reached; the pressure is then allowed to rise up to 30 lb. per sq. in. at which it is maintained for 10 minutes and is then lowered to 22 lb. per sq. in. at which it is maintained constant. For the remainder of the two hours' total time of boiling, the copper is open, without pressure. The after-runnings and the main wort are boiled for two hours in an open copper, but the results would probably follow from boiling the main wort under pressure. The lower the curing temperature of the malt, the higher the pressure which can be used; higher pressures are allowed for soft brewing water than for hard waters. The author prefers to boil the main wort under pressure from the beginning, rather than to boil the open first and subsequently under pressure (compare Gribat, *loc. cit.*); the coagulated albumin is thus separated at an early stage and is mostly thrown up against the copper, on which it collects as a coherent layer. When the copper is opened for the latter part of the boiling process, the foam is found to be almost perfectly clear and without "top-fermentation" aroma. For mild ales it is better to add the hops after the pressure-boil, since the pressure increases the extraction of the bitter; for bitter ales, on the other hand, and where the hops are scarce, this increased extraction, obtainable by boiling under pressure, may be advantageous, and if the colour will not admit of the wort being brewed under pressure, a portion of the hops may be thus extracted with water.—J. F. B.

Wine Brandies: Composition of — X. Roux. Comptes rend., 1905, 140, 511—512.

THE author has studied the relative proportions of the various volatile matters existing in the wines of the Charentes district and in the brandies prepared there. It was found that the brandies contained only a very small proportion of the acids of the wines, the greater proportion being of the aldehydes, a very large proportion of the esters, and nearly the whole of the higher alcohols (the furfural, of which only traces are present in the wine, is produced to a greater or less extent according to the manner of heating during distillation. The ethyl and higher alcohols are the most important constituents).

both as regards quantity and effect on the The relative proportions of these bodies in end on the conditions under which fermentation carried out. The author has noticed that when- as or brandies are poor in ethers, they are cor- sely richer in higher alcohols.

Following table shows the range of results obtained analysis of 22 samples of brandies distilled from isse wines of the 1901 vintage, expressed in grms. of absolute alcohol:—

	Maximum.	Minimum.	Mean.
.....	37.7	10.0	18.6
.....	33.5	3.8	14.6
.....	213.0	65.9	121.0
.....	292.4	115.0	211.4
.....	4.4	0.2	2.4
of total impurities	475.6	280.1	367.5
higher alcohols and	420.0	235.2	333.9
ether alcohols	4.4	0.7	1.9
ethers			

w of the fact that the proportions of higher and ethers vary very largely and in an inverse the author suggests that a more valuable of purity might be found in the sum of the two, ows less tendency to variation than the ratio.

—J. F. B.

rom Pears ("Brantwein"): Manufacture of K. Windisch. Z. Spiritusind. 1905, 28, 87—88.

le only the small, unripe pears, unsuitable for perry, are converted into spirit, but it is more o to use sound, ripe pears. The pears must be to a pulp, and the thick mash requires to be with water before it can be worked properly. great mistake to ferment the must at too low a ure; the diluting water should be warmed to a ure not exceeding 40° C., and the fermentation uld stand in a warmed room. A wild yeast, *lutus*, which has a low fermentative power and tendency to produce acetic acid, is very prevalent a. It is therefore advisable to pitch the pear- h a prepared yeast, at a temperature of at least r preferably at 20° C. Beer yeast is generally d, but it is not very suitable and is apt to injure a of the spirit. It is far better to use wine yeast, ay be cultivated in the pure state or else obtained sediments in the fermentation casks after racking wine. The best way of pitching the pear-musts l 2—3 per cent. of grape must in active fermenta- f cask-deposits be employed, the yeast should re- vivified. The ferment should be well mixed : diluted pear-pulp immediately after grinding. musts show an exceptional tendency to acetifi- because the mares rise and form a crust on the he liquid, in which the aerobic bacteria develop. ause the must is deficient in natural acid. Fer- on should, therefore, be conducted in closed casks pped bung-holes, or else the mares should be kept y by a perforated plate. Fermentation is complete weeks, but acetified musts do not attenuate ely. Full attenuation is reached with 0.2—0.25 of residual sugar. The liquid should be distilled as fermentation is finished, otherwise acetification be avoided. Distillation is generally carried out stills; with direct firing the danger of scorching great, owing to the tendency of the mares to settle bottom; this may be obviated to some extent by eal stirrers, or by placing blocks of wood at the of the still. Small pears, poor in sugar, yield only res of absolute alcohol per 100 kilos. of fruit, fully as yield 3—3.5 litres; under very good conditions s of pear-pulp yield 6 litres of alcohol. The spirit led in an alcoholic strength of 45—50 per cent. by —J. F. B.

Denaturing of —: Criticisms on Lindet's rt to the French Government. R. Duchemin.

Bull. Assoc. Chim. Sucr. Dist., 1905, 22, 668—682. (See this J., 1905, 146).

The author enumerates several reasons for the rejection of the denaturing agent proposed by Lindet and shows that the only security lies in the maintenance at the high proportion of wood spirit at present employed by the French Excise.

Wood spirit is the only practicable denaturing agent which cannot be eliminated from the alcohol, and the proposed reduction in its proportion would make fraudulent blending (after redistillation) five times more profitable than it is at present. The other denaturing agents proposed are both objectionable and capable of elimination. The author contends that it is quite possible to convert formaldehyde into formic acid by the action of peroxides, and even if traces were still present, as stated by Lindet, the quantities detected by the latter are so minute that no legal action could be taken, in view of the fact that formaldehyde occurs in nature. Moreover, the irritant action of formaldehyde would prevent the use of the spirit in closed rooms and the production of formic acid under the influence of heat and oxygen would render it unfit for motor purposes. Pyridine is unsuitable because of its disgusting odour, its limited supply, and rising price. The recognition of the occurrence of methyl alcohol and formaldehyde in natural products has led to the conclusion that Trillat's test is too delicate for Excise purposes, and that some less sensitive reaction should be employed; this again, is an additional reason for maintaining the high proportion of methyl alcohol added for the purpose of identifying denatured alcohol in blended spirits.—J. F. B.

Wines, Wash or Beer; Fermentation of —, and Making of Yeast for Distillers. E. Vignier, London. Eng. Pat. 3196, Feb. 9, 1904.

THE must or wort is fed from a containing vessel automatically at regular intervals in fractional portions into the fermentation tun, in which "about a foot of yeast" in active fermentation is first introduced. The fermentation tun is preferably closed and provided with means for supplying hot and cold air to the interior, and for withdrawing the air and fermentation gases through filtering and washing vessels, so as to retain the alcohol and ether vapours. The fermentation of successive fractions of the must separately enables a product of higher alcoholic strength to be obtained than in the ordinary manner.

Separating Oily Impurities from Water; [Electrical] Apparatus for —, H. T. Davis and E. Perrett. U.S. Pat. 783,107, Feb. 21, 1905. XI A., page 281.

XIX.—PAPER, PASTEBOARD, Etc.

Waste Paper; Removal of the Printers' Ink from —, C. Wurster. Papier-Zeit. 1905, 30, 611.

WASTE printed papers can be worked up very advantageously in the pulping engine without boiling, provided that the pulp is afterwards sufficiently washed in the washing hollander. The printed paper is fed in the dry state into the pulping engine together with a

stream of warm water and a regulated proportion of caustic soda solution. The soda dissolves the ink in the paper size and in the printers' ink, and the soda forms an emulsion with the carbon. In the case of papers a proportion of soap may be added. The effect of the resulting stock depends on the thoroughness of the washing process; with sufficient washing in the hollander a dull white is obtainable. It is desirable to make the washing waters faintly alkaline to facilitate the emulsification of the carbon. When mechanical pulp is present, the action of the alkali produces a tint, which, however, is discharged by alum. Long loading and short fibres are lost in the washing. Bleaching of the pulp is unnecessary, since the pulp is coloured as it would be if the paper were boiled with sodium carbonate.—J. F. B.

Silky Finish on Textile Fabrics or Paper; Employing Bowls or Rollers for Producing an improved —, J. Pope and J. Hübmner. Eng. Pat. 4907, Feb. 25, 1905, page 273.

Cotton Seed Hulls; Treatment of —, to Obtain Products therefrom [Cellulose, Sugar and Fuels] —, C. F. Cross, London. Eng. Pat. 8545, April 13, 1905.

COTTON-SEED hulls are heated with twice their weight of an alkali solution (e.g., a 3–5 per cent. solution of soda) for 6–8 hours, at a pressure of 20–40 lb. The solution thus obtained is suitable for use as a size in the manufacture of paper and boards. The fibrous product is washed and treated with chlorine until the colour is uniform. The mass is then washed and digested, at 80°–100° C., with an alkaline solution (preferably six parts of sodium carbonate and three parts of sodium silicate dissolved in 300 parts of water, and 100 parts of the chlorinated product). The product thus obtained consists mainly of a mixture of two forms of cellulose differing in length of the individual fibres. These may be separated either by suspending in water and passing through a series of tanks, when the shorter cellulose settles first; or they may be separated by washing on a sieve of suitable mesh (e.g., 40 to the inch). The longer form of cellulose may be used for many of the purposes to which cotton cellulose is applied; the shorter form is characterised by the fact that, on hydrolysis, it yields a considerable quantity of an easily crystallisable furfural may be obtained from the syrup residue after the crystallisation of the sugar, by distilling with 30 per cent. sulphuric acid.—T. F. B.

UNITED STATES PATENT.

Paper Pulp; Process of Manufacturing Chemicals from —, R. Roe, jun., Amberg, Wis., Assignor to R. Roe & Co., Providence, R.I. U.S. Pat. 783,137, Feb. 21, 1905.

THE raw material ("natural vegetable substance") is introduced in small fragments into the digester. A suitable quantity of the chemical liquor at an exact strength is then introduced at or near the top of the digester. The contents of the digester are then stirred to the proper concentration by the introduction of steam near the bottom, at which place also steam is passed.—J. B.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES, AND EXTRACTS.

Ether; Oxidising Action of Impure —, A. J. Limco. Ber. 1905, 38, 774–775.

ETHER which is not specially purified is liable to contain in addition to water, alcohol and free acid, traces of hydrogen peroxide, ozone, aldehyde and ethyl peroxide. The action of these oxidising agents is not often apparent, but the author quotes a case in which, during the extraction of a substance, the ether was found to be

alkyl iodide from an aqueous solution, the portion acquired a yellow colour and a copious sation of insoluble periodides took place. Direct ents showed that ether to which hydrogen peroxide added, possessed this property of oxidising the lide to a slight extent, but the oxidising power of roxide would appear to be a much greater one, since vely small quantity of the ether in question was of decomposing the alkyl iodide completely with on of periodides. This ether had been taken from of perfectly pure ether, but it had remained in a ttle exposed to the action of the air for about three during which period evaporation had been ing slowly.—J. F. B.

[Formaldehyde]; Commercial Preparation of —. Morel. J. Pharm. Chim., 1905, 21, 177—183.

Formol is obtained by passing the vapour of spirit, in the presence of air, over copper heated 288.

figure illustrates the plant used in the French works of the Côte d'Or, in which wood spirit d from the destructive distillation of wood in rundry and Champagne districts, is used as the of the formaldehyde.

essential part of the apparatus is the metal chamber which the feed-tube *m* enters, and from which four copper tubes or oxidisers *B* discharge by a exit tube. This chamber is fitted with inspection es, through which the course of the process may ched and controlled. The wood spirit, stored in ervoir *R*, falls into the mixer *M*, where it is vola- and intimately mixed with air from the chamber *A*, is connected with a force-pump. The gases after ing the oxidiser are led into the condensing coil *D*; c crude formol is discharged into the receiver i. The small amount of uncondensed gas is then ough a series of two washers *L*. The "formol" tained is a mixture of water, methyl alcohol and 0 per cent. of formaldehyde. It is rectified in the ll by which the free methyl alcohol is removed and mol obtained, containing 40 per cent. of formal- y, chiefly in the form of the acetal. Rectification ot be pushed too far, otherwise the formaldehyde come polymerised into trioxymethylene. n once oxidation starts, the heat generated is nt to keep the oxidisers red-hot, so that the process automatically.—J. O. B.

; Metallic —. Maystre. Schweiz. Ver. anal. a., Jan. 17, 1905; Chem.-Zeit., 1905, 29, 199.

trates of barium, strontium, calcium, lead, man- and zinc were examined. All contain water of lisation. The solubilities in water of the calcium, nd zinc salts diminish with rise of temperature, at of the barium salt increases, while those of the um and manganese salts first, increase and then sh. For the quantitative determination of the acid rium and lead salts are best suited; the latter is nsoluble in presence of alcohol.—J. T. D.

Endimino-triazoles. M. Busch. Ber., 1905, 38, 856—860. SYMMETRICAL trialkyl derivatives of aminoguanidines react with carboxylic acids to form heterocyclic compound—endiminotriazoles. The compound obtained from triphenylaminoguanidine and formic acid according to the equation:

is characterised by forming a nitrate almost insoluble in water, and well suited for the detection and determination of nitric acid (see page 291). It can be prepared in the following manner:—Twenty grms. of thiocarbamide are heated with about 0.5 litre of dry benzene under a reflux condenser, and dry mercuric or lead oxide is added in small portions, so long as a black precipitate is produced. The metallic sulphide is filtered off, the hot solution treated with the calculated quantity (10 grms.) of phenylhydrazine, and concentrated to 50 c.c. On cooling, if necessary with addition of some gasoline (petroleum spirit), the liquid solidifies to a crystalline mass of triphenylamino-guanidine. This is drained, washed with ether, dried, and then heated for two hours in a sealed tube at 175 C. with twice its weight of 90 per cent. formic acid. The product is treated with 10 times its volume of water, filtered, and the new base, 1,4-diphenyl-3,5-endanilodihydrotriazole, precipitated by ammonia, and extracted with chloroform. The chloroform solution is dried with potassium carbonate, concentrated to one fourth, and after addition of a few drops of petroleum ether, allowed to crystallise.—A. S.

Calycanthus Glaucus; Crystalline Alkaloid of —. H. M. Gordin. J. Amer. Chem. Soc., 1905, 27, 144—155.

CALYCANTHINE was obtained from the seeds of *Calycanthus glaucus* (which contain about 2 per cent.) by extraction with hot alcohol, converting into the sulphate, washing with acetone (in which it is insoluble) and liberating from the aqueous sulphate solution by means of potassium hydroxide. Calycanthine crystallises from a mixture of acetone and water in colourless crystals containing half a mol. of water of crystallisation; m. pt., 216°—218° C. By heating for three or four hours at 120° C., it loses its water of crystallisation, the anhydrous alkaloid melting at 243°—244° C. Its composition is represented by the formula $\text{C}_{11}\text{H}_{11}\text{N}_2$; it is monobasic, and the solutions of its normal sulphate and hydrochloride are strongly acid to litmus. The hydrochloride, hydrobromide, hydriodide, chloroplatinate, acetate, and sulphates are described, and also some reactions of the alkaloid; these include the rapid reduction of gold salts in alkaline solution (with a 1/1,000,000 solution of alkaloid, a purple coloration is produced); the production of a pink colour with sulphuric acid and sugar, and of a green colour with nitric acid. Physiologically, the alkaloid produces depression of the heart and stimulation of the spinal cord, the symptoms being very similar to those associated with strychnine.—T. F. B.

Organic Acids; Electrolysis of —, by means of Alternating Currents. A. Brochet and J. Petit. XI A., page 280.

Barbituric Acid; Manufacture of Derivatives of — [Dialkylbarbituric Acids]. C. D. Abel, London. From Act.-Ges. f. Anilinfabr., Berlin. Eng. Pat. 8302, April 11, 1904.

DIALKYL-BARBITURIC acids are prepared by the condensation of the corresponding dialkylmalonic acid diamide with a dialkylcarbonate in presence of an alkali alcoholate, with

or without the use of a suitable solvent. The reaction takes place according to the equation—

when diethyl carbonate has been employed. The sodium salt of the dialkylbarbituric acid is decomposed by the addition of mineral acid to its aqueous solution. (T. F. B.)

Cresote: Process of Treating —, and Product of same [for Medicinal Purposes]. A. G. Meyer, San Francisco, U.S.A. Eng. Pat. 28,997, Dec. 30, 1904.

Nitric acid is added to a mixture of beech-wood cresote, acetanilide, and ammonium carbonate, and the product crystallised from dilute alcohol. The solution of the resulting crystals in a mixture of water, alcohol and ether is intended for use in the treatment of diphtheria, tuberculosis, &c., and also as a local antiseptic. (T. F. B.)

UNITED STATES PATENTS.

Pseudo-cyclohexalidene Acetone and Process of Making same. G. Morling, Frankfurt, and R. Welde, Assignors to Farbwerke vorm. Meister, Lucius und Brünig, Höchst on the Main, Germany. U.S. Pat. 782,689, Feb. 14, 1905.

PSEUDO-CYCLOHEXALIDENE acetone is obtained by condensing with acetone the mixture of aldehydes produced by distilling the calcium salt of trimethylcyclohexenecarboxylic acid with calcium formate. (See Eng. Pat. 3173 of 1903; this J., 1904, 204.) It is a colourless oil, b. pt. 133° C. = 135° C. (8 mm. pressure), soluble in alcohol, ether and benzene, and possesses the odour of violets. Its homologues are similar in character, all possessing floral odours, and being suitable for the preparation of perfumes. (T. F. B.)

Cream of Tartar: Process of Making —. G. W. Hooven, Englewood, N.J., and S. T. H. K. Endemann, Brooklyn, Assignors to California Products Co., Jersey City. U.S. Pat. 783,524, Feb. 28, 1905.

ONE ton of pomace is extracted with a solution of 36 lb. of oxalic acid in 1200 gallons of water and the solution is evaporated to produce cream of tartar. The residual pomace is extracted with hot water, and a further quantity of oxalic acid is added to the resulting liquor, which may then be used again for the extraction of a fresh quantity of pomace. A potassium salt may, if desired, be added to the oxalic acid solution used for the extraction. The method of converting calcium tartrate into potassium bitartrate by boiling with a solution of oxalic acid and a potassium salt is also claimed. (T. F. B.)

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Photographic Impressions produced by Field Illuminations; Intensity of —. C. Gutton, Comptes rend. 1905, 140, 573–575.

PHOTOGRAPHIC plates, half of each being protected by an opaque screen, were exposed for one minute in an otherwise dark room to the light from an electric lamp, at different distances, starting from the greatest distance at which any effect was produced. The plates were developed, and the density of the photographic impression was measured by photometric comparison of the exposed and unexposed halves of the plates. The results show that for very low illuminations the density of the impression increases very rapidly with increase in the illumination, but that this rate of increase diminishes very much at higher illuminations; contrasts of light and shade are thus exaggerated in a negative. When, however, a positive is printed from a negative, the same process is

effective, so that the exaggeration is reduced, the densities of impression are proportional to the illuminations, and the differences of illumination are faithfully reproduced. (J. T. D.)

Hydrogen Peroxide: "Radiation" of —. J. Graetz and C. Otsuki, Verhandl. der Deutsch. Physik. 1905, 7, 53–56.

GRAETZ (this J., 1905, 43) has recently explained the action of hydrogen peroxide on a photographic plate as being due to a kind of radiation. The authors' experiments on the subject showed that in all the cases examined where photographic action took place, the presence of hydrogen peroxide could be detected on the film in reaction with titanium-sulphuric acid. They concluded that the action on the photographic plate is caused by hydrogen peroxide which has condensed thereon. (See also Russell, this J., 1899, 516.)—A. S.

Ozone: Photographic Activity of —. K. S. Russell, Physik. Zeits., 1905, 6, 73–74. (Chem. Centr., 1905, 586.)

OZONE acts on photographic plates even when no other substances are present, and therefore when no hydrogen peroxide can form. The reason why Graetz (this J., 1905, 43) did not observe any action is probably the remarkable differences in sensitiveness to the different kinds of plates on the market. Agfa plates when subjected to a current of ozonised oxygen for a few minutes were strongly acted upon, whilst reversal image began after 8 minutes. The different behaviour of the plates is due to the gelatin used in preparing the films.—A. S.

Metals: Spontaneous Action of — on Photographic Plates without Direct Contact. G. W. A. Kay and M. Steffens, Physik. Zeits., 1905, 6, 19. (Chem. Centr., 1905, 1, 579.)

IN the earlier experiments (this J., 1905, 104) the action of the photographic plate had been observed on metals which had been frequently exposed to light, and it was thought that a concentration of radio-activities at the surface of the metal might have taken place. However, further experiments have shown that plates which have not been exposed to radium rays or other radioactive substances behave exactly like those which have been so exposed. Also, plates of aluminium and zinc which had originally produced images on a film placed above them, when placed property after exposure to X-rays, but still acting as a film placed below them. The authors state that none of their results is opposed to the view previously put forward that the effects produced ("actinography") are due to an emanation which is subject to the law of gravity. Occasionally a light image on a dark background was produced. Zinc, aluminium and uranium "actinographs" on plates placed both above and below the other metals only on the lower plates.—A. S.

ENGLISH PATENTS.

Photographs; Impts. Relating to —. O. Fulton, Chesham, and W. M. Gillard, Twickenham. Eng. Pat. 1018, March 11, 1904.

THIS specification relates to the production of "dual" photographs (see Eng. Pat. 11,219 of 1903; this J., 1904, 622) upon paper or similar material. The treatment of a celluloid solution, which is employed for "dual" photographs on woven fabrics (*loc. cit.*), is not applied to paper, since it makes it too transparent. The paper may be impregnated with a solution of gum or gelatin and then hardened with chrome alum or formaldehyde, but it is preferable to use a solution of cellulose (*e.g.*, a solution of cellulose in cuprammonium). The paper on which the photograph is to be produced is preferably of the "parchment paper" type; it should be more transparent than ordinary paper, and more opaque than a waxed or varnished paper. The paper is first

l with a solution of cellulose, as defined above, then dried, calendered, and coated on both sides with a sensitive gelatin emulsion. The subsequent operation of the duplex photographs, and the results obtained are similar to those described in the above-mentioned specification.—T. F. B.

or other Material for Photographic Purposes; Making or Preparation of ——. J. H. P. Gillard, R.; and H. H. Molyneux, Hampstead. Eng. Pat. 27, Nov. 28, 1904.

ture of starch and agar-agar is employed in place of gelatin, &c., as an emulsifier for the sensitising salts in photographic paper, &c. A solution of 36 grs. of agar in 5 oz. of water may be added to a solution of 1 oz. of starch in 8 oz. of water; if a somewhat softer gelatin is desired, sugar, glycerin, &c. (e.g., 60 grs.) may be added to the above mixture. The preparation may be applied to the paper, and the whole sensitised by immersion in a suitable solution, or the sensitising agents may be incorporated with the mixture, and the product applied to paper. (Compare Eng. Pat. 26,247 of 1904; 1905, 152).—T. F. B.

VII.—EXPLOSIVES, MATCHES, Etc.

Explosives; Preparation of ——. M. Neumann. Eng. Pat. VII., page 276.

ENGLISH PATENTS.

Explosives; Manufacture of —, and of Caps for use with. R. A. Hadfield, Sheffield, Yorks. Eng. Pat. 7882, April 5, 1904.

A projectile is preferably made of nickel-chromium containing carbon (0.6 per cent.), nickel (2 per cent.), and manganese as low as possible. For the purpose of hardening it is heated to 720° C., and is then dipped, point downwards, to "zone" into oil or water, the remainder of the projectile being out of the cooling medium. By this means the portion which has been dipped in the cooling medium is hardened, and the projectile gradually becomes harder towards the base. Caps for projectiles are hardened by heating them to between 950° C. and 1100° C., and quenching in water, re-heating between 600° C. and 700° C., and cooling slowly.—G. W. McD.

Explosives; Sulphur Compounds and Priming or Igniting Compositions suitable for the Manufacture of ——. J. Vetter, London. From the Firm of J. D. Riedel, Berlin. Eng. Pat. 7893, April 12, 1904.

Eng. Pat. 342,040 of 1904; this J., 1904, 911.—T. F. B.

XXIII.—ANALYTICAL CHEMISTRY.

APPARATUS, Etc.

Apparatus for Determination of — Loss of Weight. L. L. Kreider. Z. anal. g. Chem. 15, 44, 154—157.

The apparatus consists of the test-tube A (see figure), which fits as closely as possible the second test-tube B, and has a small hole blown in the bottom, and

in which slides loosely the third test-tube C, drawn out to a capillary, and provided with a tight cork and glass tube, the latter furnished with a rubber tube and glass-rod stopper. The hole in B is loosely plugged with cotton-wool, the capillary passed through it and calcium chloride packed in B to a convenient height. A tube very slightly smaller than B is placed in A, and a good paraffin joint made between them; the joint is then warmed and the inner tube withdrawn, leaving the paraffin on the walls of A. The weighed substance for analysis is placed in A, and the reacting liquid sucked into C, and retained by closing the stopper. The apparatus is put together, the paraffin joint made good by a hot wire, and the whole weighed. The liquid is gradually run in, and after reaction is over, a current of air is passed through till the gaseous product of reaction is expelled, when the final weighing is made. Results of decomposition of carbonates by acids, of acids by magnesium and zinc, and of urea and ammonium salts by hypobromite, are given, and show that a high degree of accuracy is attainable.—J. T. D.

INORGANIC—QUANTITATIVE.

Benzene as an Indicator in Iodine Titrations. B. Schwezwow. Z. anal. Chem., 1905, 44, 85—88.

If a few cubic centimetres of pure benzene be added to a solution containing free iodine, and the latter then titrated in the usual way, the end point is shown by the disappearance of the last trace of violet-red coloration from the benzene. The colour change is stated to be more easily observed than is the case when starch solution is employed. Benzene is also the more sensitive indicator, 1 c.c. of N/10000 iodine solution giving a distinct coloration in 5 c.c. of benzene, whilst 5 c.c. of starch solution required 2.5 c.c. of the iodine solution, both experiments being performed at a temperature of 15° C. The objection to this indicator is that the titration must be carried out in a stoppered vessel, so that the solutions can be well shaken to remove the last traces of iodine dissolved in the benzene.—W. P. S.

Persulphate; Quantitative Separations by means of —. G. v. Knorre. Z. anal. Chem., 1905, 44, 88—96 (See this J., 1904, 133.)

FURTHER experiments are described which were carried out for the purpose of ascertaining whether the author was justified in his previous statement that the precipitated manganese peroxide always carried down with it traces of other metals present in the solutions employed. It was found that copper oxide was always precipitated together with manganese peroxide from solutions containing manganese and copper salts, and that it was not possible to free the precipitate from copper by boiling with 2 per cent. nitric acid. The author, therefore, considers his former statement confirmed.—W. P. S.

Nitric Acid; Gravimetric Determination of —. M. Busch. Ber., 1905, 38, 861—866.

THE author finds that diphenylendianilodihydrotriazole (for its preparation see page 289) is a very suitable reagent for the detection and gravimetric determination of nitric acid. For ordinary use, the name "Nitron" is proposed for the new base.

Detection of Nitric Acid, free and combined.—Five to six c.c. of the solution under examination are acidulated with 1 drop of dilute sulphuric acid, and 5—6 drops of a 10 per cent. solution of "Nitron" in 5 per cent. acetic acid are added. If nitric acid be present, a voluminous white precipitate is produced, or if the quantity be very small, fine needles separate after some time. One part of nitric acid in 60,000 can be detected at the ordinary temperature, and 1 in 80,000 at 6° C. The addition of sulphuric acid favours the reaction, but may be omitted if necessary.

Some other acids also give precipitates, but these can in most cases be easily removed before making the test, namely, hydrobromic acid by means of chlorine, hydroiodic acid by oxidation with iodate and separation of the iodine, and nitrous and chromic acids by treatment with hydrazine sulphate. Chloric (1:10,000), perchloric (1:50,000), thiocyanic (1:15,000), ferrocyanic, ferricyanic and picric acids also interfere.

Determination of Nitric Acid.—The substance containing about 0.1 gm. of nitric acid is dissolved in 80–100 c.c. of water, 10 drops of dilute sulphuric acid are added, the liquid is heated nearly to boiling and treated with 10–12 c.c. of the solution of nitron in acetic acid. The mixture is allowed to stand for 1½–2 hours in ice water, the precipitate collected in a Nørbauer crucible (Z. angew. Chem., 1901, 923), washed with the filtrate, and then with 10–12 c.c. of ice-water in small portions. The precipitate is dried at 110° C., and weighed, the weight multiplied by $\frac{97}{100}$, giving the amount of nitric acid. The nitron may be regenerated from the precipitate by shaking with ammonia and extracting with chloroform.

Detection and Determination of Nitrate in presence of Nitrite.—The substance is dissolved in a small quantity of water, and the solution allowed to drop gradually on to finely-powdered hydrazine sulphate contained in a beaker cooled externally with flowing water. When the evolution of nitrogen, due to the decomposition of nitrite, has ceased, the solution is made up to 100 c.c., and treated with nitron in the manner described above.—A. S.

Bismuth Ammonium Molybdate; Application of — to Gravimetric Analysis (Determination of Bismuth). E. H. Miller and F. V. D. Cruser. J. Amer. Chem. Soc., 1905, 27, 116–121.

THE precipitate of bismuth ammonium molybdate obtained by precipitating acidified bismuth solutions with excess of ammonium molybdate, may be utilised for the gravimetric determination of bismuth, since it is converted on ignition into a mixture of bismuth and molybdenum oxides of the composition $\text{Bi}_2\text{O}_3 + 4\text{MoO}_3$. By washing the molybdate precipitate with ammonium nitrate solution, drying at 160° C., and igniting at a dull red heat, results were obtained which showed that this process was capable of as great accuracy as the volumetric method of Miller and Frank (this J., 1903, 1149). In the course of preliminary experiments, it was found preferable to carry out the ignition of bismuth nitrate in a porcelain crucible, the results obtained when a platinum vessel was used, being somewhat low. In the precipitation of bismuth ammonium molybdate, Congo Red is preferable to Methyl Orange as an indicator, and washing the precipitate with ammonium nitrate solution gives more accurate results than when ammonium sulphate solution is used.—T. F. B.

Phosphorus [in Iron and Steel]; Colorimetric Determination of —. T. E. Hewitt. J. Amer. Chem. Soc., 1905, 27, 121–124.

IT is proposed to determine phosphorus by comparing the colours produced by passing sulphuretted hydrogen in excess into solutions of sodium phosphomolybdate in alkali hydroxide. The standard phosphomolybdate solution is of such a strength that 10 c.c. contains 0.000009122 gm. of phosphorus; 10 c.c. of this are diluted to 25 c.c., saturated with sulphuretted hydrogen, and made up to 50 c.c. For the determination of phosphorus in iron or steel, 2 grms. of the latter are dissolved, and the phosphorus obtained as phosphomolybdate; this is dissolved in decinormal sodium hydroxide solution, and the volume made up to 100 c.c. Portions of this solution are saturated with sulphuretted hydrogen, made up to 50 c.c., and compared with the standard.—T. F. B.

Tungsten [in Tungsten Steels, &c.]; New Method of Determining —. G. v. Knorre. Ber., 1905, 38, 783–789.

BENZIDINE hydrochloride precipitates not only sulphuric acid, but also tungstic acid, from its solutions. The benzidine tungstate so obtained is insoluble in cold, but slightly soluble in hot water. When precipitated in the cold

it readily passes through the filter; it must, therefore, be precipitated from a boiling solution, which is allowed to cool completely before filtration, or a little sulphuric acid may be added to the cold solution before precipitation in which case the mixed benzidine sulphate and tungstate settle rapidly and filter clear. The benzidine solution is made according to Raschig's directions (this J., 1906, 1066), but using half the quantities there given, so that 1 litre contains 20 grms. of benzidine; 1 c.c. is equivalent to about 0.025 gm. of tungstic acid, or about 0.01 of sulphuric acid. The precipitate is washed with solution diluted with 30–40 times its volume of water as pure water carries some of the precipitate through. To the solution (of sodium tungstate, for example) containing about 0.5 gm. of tungsten, 10 c.c. of N/10 sulphuric acid are added, and an excess of the benzidine solution; after 5 minutes the liquid is filtered, the precipitate washed with the weak benzidine solution, moist filter and precipitate placed direct into a porcelain crucible, ignited, and the resulting tungstic anhydride weighed.

In the case of tungsten compounds which have been fused with sodium carbonate, the aqueous solution of fusion is neutralised with hydrochloric acid, using Methyl Orange as an indicator, 10 c.c. of N/10 sulphuric acid are added, and the precipitation and further operation carried out as above. Practically all the color matter goes down with the precipitate, but is, of course, burnt off during the ignition.

Tungsten steels are dissolved (5 grms.) without loss of air in dilute hydrochloric or sulphuric acid, the residue of the tungsten remaining undissolved. The solution filtered, the residue washed on the filter with the benzidine solution, ignited, fused with sodium carbonate, the fusion extracted with water, filtered, and the soot treated as above. Results in a sample of tungsten steel

Solution by hydrochloric acid:—	Tungsten Per cent.
Crude residue calculated as WO_3	1.45
Tungsten by benzidine process	1.25
Solution by sulphuric acid:—	
Crude residue calculated as WO_3	1.31
Tungsten by benzidine process	1.20
Tungsten by method hitherto used	1.11

The precipitation of benzidine tungstate is interfered with by ferric salts, but not by ferrous salts. In presence of tartaric or citric acid added to prevent the oxidation of ferrous salts, the results are always too low, considerable quantities of free acid also interfere with the precipitation of benzidine tungstate. (Compare this J., 1905, 106.)—J. T. D.

Copper Sulphide; Solubility of — in Solutions of Polysulphides. V. Hassreider. Z. angew. Chem., 1905, 18, 292.

COPPER sulphide is soluble in solutions of yellow polysulphide, particularly so in the presence of polysulphides such as are formed on fusing metallic oxides with sodium hydroxide and sulphur. Thus, in determining copper in, e.g., tin, by fusing the oxides with equal parts of sodium and sodium hydroxide and extraction of the mass with water, from 3 to 64 per cent. of the total copper may pass into solution (Prost and van de Casteele). Rönne has shown that nearly all the sulphide remains in the residue if the fused mass be extracted with cold water whilst a current of hydrogen is simultaneously introduced. The author recommends the simpler method of treating the solution of the polysulphides with repeated addition of sodium sulphite until the liquid becomes colorless, sodium thiosulphate and monosulphide being formed.

This method is stated to have given quantitative results in the separation of copper from antimony and lead. A similar treatment with sodium sulphite has been recommended by Leerenier to convert polysulphides into monosulphides so as to obtain solutions suitable for electrolytic determination of antimony.—C. A. M.

Assay of —. E. Victor. Chem.-Zeit., 1905, 29, 179.

ample, if not in the form of borings or filings, is cut into a thin sheet and cut into small pieces. 5 grms. are heated with 100 c.c. of hydrochloric acid (124) to a moderate temperature until the decomposition is complete. After cooling, potassium chlorate is added in small portions until the black residue consisting of antimony and arsenic is dissolved, and the clear solution is boiled until the chlorine is completely off. After cooling, a solution of ammonium and ammonia in slight excess, is added; the solution should then be blue, or, if iron be present, greenish-yellow. Copper, lead, iron, and bismuth are precipitated by unfiltered hydrogen water. Lead and copper may be removed electrolytically, bismuth and iron, gravimetrically. For the determination of antimony, the blue solution sample is reduced with "ferrii reductum"; metallic antimony is precipitated. This is filtered off, together with the iron, and dissolved in hydrochloric acid with the aid of potassium chlorate. The solution is then made alkaline, the ferric hydroxide is filtered off by filtration through asbestos, the other metals in the filtrate are determined as follows:—The solution of sodium sulphide and a little potassium is added. In the remaining solution the antimony is determined electrolytically.

Amplified containing less than 96 per cent. of tin, is determined volumetrically. The sample is dissolved as described above, and the solution reduced by aluminium powder in a current of hydrogen. Hydrochloric acid is added to dissolve the residue which is titrated by ferric chloride and iodine. The solution is used as an indicator.—R. L.

Phosphates: Technical Method for the Determination of Phosphoric Acid in —. Gerhardt. Chem.-Zeit., 1905, 29, 178.

Stomachary titration of the aqueous or alcoholic solution from superphosphates is not very accurate. The author recommends adding a certain quantity of the phosphate solution to a weighed excess of calcium carbonate:

For determining the unattacked calcium carbonate, the solution is left undissolved, is filtered off, introduced into a 200 c.c. flask together with the filter paper, and 10 N/1 hydrochloric acid added, the solution made clear, filtered through a dry filter, and an equal part of the filtrate titrated with N/2 sodium hydroxide solution with methyl orange as indicator. The use of iron and alumina does not affect the accuracy of the result.—R. L.

Ammonia in Milk: Determination of —. W. N. Berg and I. C. Sherman. J. Amer. Chem. Soc., 1905, 27, 136.

For determining ammonia in milk by distillation, the use of calcium carbonate at atmospheric pressure invariably gives false results, even when very small amounts of alkali are used; the use of corrections deduced from the amounts of ammonia given off on further distillation gave little result. The most accurate method was found to be the modification of the Boussingault-Schaeffer method, carried out as follows:—A mixture of 50 c.c. each of 10 N/1 and methyl alcohol, with 10 grms. of sodium carbonate and 0.5 gm. of sodium carbonate, is distilled under a pressure of about 50 mm. (56°–62° C.) for about 15 minutes, the distillate being collected in standard sulphuric acid. The total volume of the distillate should be noted. A correction for methyl alcohol is necessary (0.5 c.c. N/1 alkali for 40–50 c.c. of distillate). The use of sodium chloride is not necessary in the case of fresh milk, but in old milk considerably less ammonia was generally obtained when sodium chloride was present. In the latter case the difference in the amounts of ammonia obtained with and without sodium chloride is considered

to be of value as an indication of the condition of the proteid matter. The presence of formaldehyde in the milk had no effect on the results. T. E. B.

ORGANIC QUALITATIVE.

Sugar in Water of Condensation: Test for —. H. and L. Pellet. Bull. Assoc. Chim. Sac. Dist., 1905, 22, 582–584.

The maximum of coloration in applying the α-naphthol test for sugar is obtained at a certain temperature; the best conditions are attained by measuring 5 c.c. of sulphuric acid into a test-tube, running 2 c.c. of the water to be tested, cautiously down the side of the tube, adding two or three drops of the reagent and shaking the mixture. It is easy to detect 2 to 3 mgrms. of sugar per litre. As Bronckmann has shown, the presence of 150 mgrms. of nitric acid per litre obscures the reaction. Ammoniacal waters do not interfere. By comparison of weak sugar solutions made up with distilled water and with the water of condensation, it may be determined whether the water obscures the test or not. Suspended matters should be removed by filtration through paper and washed with distilled water. Grease should be removed with petroleum ether. If the organic matter present in the sulphuric acid itself gives the sugar reaction even with distilled water, it suffices to heat such acid until white fumes are evolved. After cooling it gives no colour reaction unless sugar be present.—L. J. DE W.

ORGANIC QUANTITATIVE.

Sulphur [in Coal]: Determination of —. by Eschka's Method. C. Bender. Z. angew. Chem., 1905, 18, 293.

The author has obtained completely concordant results by Sauer's and by Eschka's methods of determining sulphur in coal. In the former method the combustion in oxygen was accelerated by placing a roll of platinum foil in the constricted portion of the tube. A modification of Eschka's method is used in Westphalia to prevent contact of the products of combustion with Eschka's mixture. The mixed coal and soda-magnesia are ignited in a tube of hard glass, about 18 cm. long and 2.8 to 3 cm. in diameter, which is closed at one end. The mixture is placed near the closed end of the tube, which is held horizontally. It is then heated gradually from behind forwards until the combustion is complete, after which the determination is completed in the usual manner. The tube should be heated in an air-bath before the introduction of the mixture.—C. A. M.

Benzylethylaniline and Benzyldine-aniline: Determination of —. W. Vaubel and O. Schener. Z. Färb.-u. Textil-Ind., 1905, 4, 88–89.

BENZYLETHYLANILINE and benzyldine-aniline can be quantitatively determined by the bromination method. In the case of the former, the benzyl group is split off and tribromomethylaniline formed, whilst with the latter, the benzyldine group is removed and tribromaniline produced.

The bromination is performed in the usual manner, the bases being dissolved in glacial acetic acid, hydrochloric acid and potassium iodide added, and the mixture titrated with a standard solution of potassium bromate, the end point being determined by spotting on starch-iodide paper. Benzylethylaniline and benzyldine-aniline have very weak basic properties and cannot be approximately determined by titrating with hydrochloric acid with the use of Congo Red paper, as is possible in the case of mono- and di-methylaniline and of mono-ethylaniline.—A. B. S.

Acetyl Groups: Determination of —. A. G. Perkin. Chem. Soc. Trans., 1905, 87, 107–110.

The method is recommended more particularly for acetyl

derivatives of phenolic compounds. About 0.5 gms. of the substance is treated with 30 c.c. of alcohol and 2 c.c. of sulphuric acid, and the mixture gently distilled for about three-quarters of an hour, a little fresh alcohol being added from time to time. The ethyl acetate which distils over is collected in 20 c.c. of standard alcoholic potash solution, which at the end of the distillation, is boiled for a few minutes under a reflux condenser, the excess of alkali being finally titrated with standard sulphuric acid. When the method is applied to acetylamino compounds, 4 c.c. of sulphuric acid are used, and the mixture is distilled for a longer time.—A. S.

Fats; Bromine Absorption Value of — [New Method for the Determination of]. F. Telle, J. Pharm. Chim., 1905, 21, 111—117, 183—187.

THE following method obviates the disadvantages which pertain to the customary processes, due to the volatility of the bromine, and the unstable titre of its solutions. At the same time only the total additive bromine is determined, and errors due to more or less complete substitution are avoided.

The requisite solutions are:—*Solution of arsenic trioxide*.—4.95 grms. of pure dry arsenic trioxide are dissolved in 10 c.c. of caustic soda solution, rendered acid by the addition of 100 c.c. of hydrochloric acid, and made up to 1 litre with distilled water. This is equivalent to N/10 bromine solution.

Solution of sodium hypochlorite, prepared by diluting 35 or 40 c.c. of the commercial solution to 1 litre. This is then titrated against the standard arsenical solution as follows:—Five c.c. of 10 per cent. potassium bromide solution are added to 20 c.c. of the solution of arsenic trioxide; the liberated bromine is then titrated with the hypochlorite solution until only a feeble yellow tint remains.

To determine the bromine absorption of a fat.—1.25 grms. of oil (or 0.025 gm. of a drying oil) are dissolved in chloroform, or preferably carbon tetrachloride, and the solution is made up to exactly 50 c.c. Ten c.c. of this solution are mixed in a stoppered flask with 5 c.c. of 10 per cent. potassium bromide solution, 1 c.c. of pure hydrochloric acid, and then slowly and with constant agitation with a known volume of the sodium hypochlorite solution. In order to avoid too great excess of free bromine, the amount of hypochlorite should not be excessive. For cod-liver and sweet almond oils 30 c.c. will be sufficient; for ordinary oils, 25 c.c.; for lard and margarins, 20 c.c.; for butters and tallows, 15 c.c.; for cocoa-nut fat, 10 c.c. The mixture is set aside in a dark place for about 20 minutes, then 20 c.c. of the standard arsenic solution are run in, and the whole well shaken. Finally, standard hypochlorite solution is run in until the aqueous solution assumes a yellow tint, which passes into the chloroform or carbon tetrachloride on agitation. The total number of c.c. consumed, minus the amount equivalent to the 20 c.c. of arsenical solution added, will be the equivalent of the bromine absorbed by the oil. This is then expressed in terms of bromine for 100 grms. of oil, in the usual manner.

Bromine absorption values by the above method.—Sweet almond oil, No. 1, 69.87, No. 2, 74.37; arachis oil, first pressing, 53.24; cotton-seed oil, 64.52; poppy-seed oil, No. 1, 76.28, No. 2, 78.69; olive oil, No. 1, 51.20, No. 2, 52.24, No. 3, 54.00; sesame oil, No. 1, 66.00, No. 2, 65.70; lard, No. 1, 35.52, No. 2, 38.3, No. 3, 40.30; butters from Rheims, 21.38; from Aisne, 23.23, from Ardennes, 25.23; oleomargarin, 28.96; cocoa-nut fat (vegetaline), 5.13; castor oil, cold drawn, 52.24; cod-liver oil, pale, 83.44, brown, 83.1; cacao-butter, 23.69; linseed oil, No. 1, 96.15, No. 2, 95.07; colza oil, 64.32; neat-foot oil, 56.03; tallow, No. 1, 25.41, No. 2, 23.86.—J. O. B.

Glycerol; Direct Method of Determining — A. A. Shukoff and P. J. Schestakoff. Z. angew. Chem., 1905, 18, 294—295.

THE method is based upon the fact that on mixing the glycerol solution with sodium sulphate dehydrated by ignition, and extracting the mass with anhydrous acetone,

the whole of the glycerol passes into solution. The liquid to be analysed is concentrated to a syrup (or to a paste in the case of soap-lyes) at a temperature not exceeding 80° C., care being also taken that the evaporation does not last too long. The amount of material taken should yield not more than 1 gm. of pure glycerol. The concentrated liquid is mixed with the ignited powdered sodium sulphate (about 20 grms.) and the nearly dry powder placed in the paper cartridge of a Soxhlet extractor, arranged as shown in the figure, and fitted together by ground glass connections. The extraction with anhydrous acetone is continued for about four hours, after which the acetone is distilled off, and any particles of fat, &c., seen on the surface of the glycerol washed off by means of petroleum spirit of low boiling point. The residue is then dried in the extraction flask, which is placed in an air-bath maintained at a temperature of 75° to 80° C., until practically constant in weight (four to five hours). The flask should be closed with a ground-in glass stopper before the final weighing. As thus obtained the glycerol is absolutely free from ash and shows over 99 per cent. of pure glycerol when analysed by Hehner's method. If the original solution contain more than 40 per cent. glycerol the preliminary concentration can be omitted and the liquid treated directly with the sodium sulphate. The method is shown to give results in close agreement with those obtained by Hehner's method, or (in the case of pure glycerol) calculated from the sp. gr. For instance, in the case of an impure soap lye, the results were 2.19 and 12.19 per cent. respectively.—C. A. M.

Tanning Materials; Analysis of —, by method of "Spongy" Alumina. H. Wislicenus. Z. anal. Chem., 1905, 44, 96—106.

THE "spongy" aluminium oxide may be obtained by strongly igniting aluminium sulphate, nitrate or carbonate, but its absorptive power is too small for the purpose. The most absorbent material is obtained by the oxidation of aluminium powder in the presence of a trace of mercury. The resulting hydroxide is washed with ether and ignited. It can be used as a hide-powder in determining the tannin substance in ordinary tanning materials, such as oak and quercus extracts. The results obtained, agree closely with those obtained by the hide powder method, but themselves for the same extract, but as a rule are higher than those obtained by the hide powder method. The tannin and colouring substances are so firmly combined with the alumina that nothing is extracted from the precipitate by treating it with hot water, or with alcohol. The precipitate of tannin and alumina may be ignited to obtain the latter again in a fit state for subsequent analyses.—W. P. S.

Pentoses; Tollens' Phloroglucinol-Hydrochloric Acid Reaction for —. E. Pinoff. Ber., 1905, 38, 76—77.

THE author recommends the following modification of Tollens' reaction for pentoses:—1.5 grms. of pentose are boiled for a quarter of an hour under a reflux condenser with 75 c.c. of absolute alcohol and a sufficient quantity of a solution of phloroglucinol in concentrated hydrochloric acid (sp. gr. 1.19). When the product is washed with alcohol and subsequently with ether, it gives a permanent solution, the colour of which is permanent for weeks. A study of the absorption spectra of the colorations showed that, according to the various proportions effected in the relative proportions of the three reagents: pentose, phloroglucinol and hydrochloric acid, solutions showing one, two or three absorption bands simultaneously could be obtained. The three absorption bands correspond to three different compounds. Under suitable conditions, solutions each showing

the three bands were obtained. The band in the portion of the spectrum, which is the characteristic pentose coloration in aqueous media, belongs to the most stable of the three compounds. The bands in the blue portions have only been observed in solutions produced in alcoholic solutions as above; and belong to labile compounds, which are converted into the more stable compound by heating with hydrochloric acid.—J. F. B.

Dextrose and Levulose: Simultaneous Determination of —. L. Lindet. Bull. Assoc. Chim. Dist., 1905, 22, 574–577.

When the rotation of levulose is increased in the case of strong acids, the influence on the results from Clerget's formula is insignificant and within limits of errors of analysis. The author prefers to use reactions before and after inversion, and the polarization before inversion as data for the calculation of the age of sucrose, dextrose and levulose.—L. J. DE W.

Potatoes: Determination of Moisture in —. Hoffmann's Method. E. Parow and G. Ellrodt. Intusind, 1905, 28, 80.

A procedure originally proposed by Hoffmann for the determination of moisture in grain (this J., 1902, 1088) is given correct results in the case of desiccated slices. The following modification, however, gives numbers which agree sufficiently closely with those obtained by direct drying:—400 c.c. of oil of turpentine used in the Hoffmann apparatus and 50 grms. of powdered potatoes are thoroughly mixed therein. The contents of the distilling vessel are rapidly heated to 158° C., the temperature is then slowly raised in 20 to 158° C., care being taken to see that not much turpentine distills over with the water. If this be done, the rise of temperature must be effected more slowly. After a temperature of 158° C. has been reached, the steam is conducted rapidly with a large flame until a shaped portion of the apparatus is three-fourths full of distillate. The flame is then removed and the water is read off after a short time, 0.2 c.c. being added to allow for the emulsified portion.

The authors have not been able to obtain satisfactory results in the case of potato starch by the method described by Hoffmann and Schulze (this J., 1903, 655).—J. F. B.

Freezing Point in Aqueous Solutions: Determination of —, by the aid of the Freezing Point. R. Gaunt. Z. anal. Chem., 1905, 44, 106–108.

The following results were obtained in a number of determinations of the freezing point of dilute solutions of —:

Alcohol grms. of solution.	Decrease of Freezing Point in Relation to that of Water.		Calculated Decrease for each 1 per cent. of Alcohol.	
	I.	II.	I.	II.
1.00	0.428 °C.	0.420 °C.	0.428 °C.	0.420 °C.
2.00	0.853 "	0.845 "	0.426 "	0.422 "
3.00	1.271 "	1.267 "	0.424 "	0.422 "
4.00	1.692 "	1.690 "	0.423 "	0.422 "
5.00	2.120 "	2.135 "	0.424 "	0.427 "
6.00	2.554 "	2.570 "	0.425 "	0.428 "
7.00	3.010 "	3.020 "	0.430 "	0.431 "
8.00	3.510 "	3.520 "	0.439 "	0.440 "
9.00	4.525 "	4.530 "	0.452 "	0.453 "
20.00	5.590 "	5.600 "	0.466 "	0.467 "

It is seen that, for solutions containing from 1 to 7 per cent. of alcohol, the decrease is proportional to the amount of alcohol present, but that for more concentrated solutions the proportion is greater. An ordinary Beckmann's thermometer was used in the determinations, and the freezing point consisted of ice, salt and water, with a temperature about –8° C.—W. P. S.

Metals: Metallic —. Maystrse. XX., page 289.

XXIV.—SCIENTIFIC & TECHNICAL NOTES.

"Bologna Phosphorus" [Phosphorescent Sulphides]. L. Vanino and J. Gans. J. prakt. Chem., 1905, 71, 196–200.

The luminosity of the phosphorescent masses, obtained by heating strontium thiosulphate or barium thiosulphate at about 1300° C. for three-quarters of an hour, is greatly increased by the addition, before heating, of small quantities of nitrate of uranium, bismuth, or thorium. If these nitrates be added to calcium thiosulphate, however, no useful result ensues. Strontium thiosulphate yields more luminescent products than barium thiosulphate. Of the many phosphorescent preparations known, the following are found to be the finest:—

1. *Lennard's Mass.*—Strontium carbonate, 100 grms.; sulphur, 100 grms.; potassium chloride, 0.5 gm.; sodium chloride, 0.5 gm.; manganous chloride, 0.4 gm. By heating the mixture for three-quarters of an hour at about 1300° C., a product is obtained which emits a fine golden yellow light.

2. *Mourel's Mass.*—Strontium carbonate, 100 grms.; sulphur, 30 grms.; sodium carbonate, 2 grms.; sodium chloride, 0.5 gm.; manganous sulphate, 0.2 gm. This mass emits a bright yellow light.

3. *Vanino's Mass.*—Strontium thiosulphate, 60 grms.; bismuth nitrate, 12 c.c. of a 0.5 per cent. solution in acidified alcohol; uranium nitrate, 6 c.c. of a 0.5 per cent. alcoholic solution. By heating the mass for three-quarters of an hour at about 1300° C., a product is obtained which emits an emerald-green light.

4. *Balmain's Mass.*—Calcium oxide (iron-free) 20 grms.; sulphur 6 grms.; starch, 2 grms.; bismuth nitrate, 1 c.c. of a 0.5 per cent. solution; potassium chloride, 0.15 gm.; sodium chloride, 0.15 gm. The mass after being heated emits a violet light.

For exciting the luminescence of these preparations, the best source of light, in absence of sunlight, is the Heraeus mercury lamp, a few minutes' exposure to its light being sufficient. Strong incandescent gas light is practicable, but is slower in its action.—H. B.

Mercury Compounds; Photographic Radiation of some —. R. de Jersey Fleming-Struthers and J. E. Marsh. Chem. Soc. Proc., 1905, 21, 67.

The authors found that the double compound of mercuric cyanide and phenylhydrazine acted upon a photographic plate without being in contact with the same, and even through a layer of paper or aluminium foil; on developing the exposed plate, a deep black patch appeared. The action of phenylhydrazine was slower and more diffused than that of the mercury compound. Of different specimens of mercuric cyanide, some were active and others inactive; the active specimens were rendered inactive by heating them. Inactive specimens became active when slightly moistened with water, but remained inactive when covered with water. Mercuric cyanide prepared from inactive mercuric oxide and hydrocyanic acid was active. Of other mercury salts, mercuric chloride was active and remained so when distilled; mercuric bromide and mercuric and mercurous nitrates were also active. Mercuric iodide, sulphate, acetate, sulphide and oxide, and mercuric ammonium chloride were inactive, or only very slightly active; as also were mercurous chloride, sulphate, acetate and oxide. Redistilled metallic mercury and cuprous, silver and potassium cyanides were quite inactive.—A. S.

Acids; Detection of the Formation of Complexes in Mixtures of — by the aid of Isohydric Solutions. R. Hofmann. Z. physik. Chem., 1905, 51, 59–64.

The author has previously shown by the aid of the law of isohydric solutions that a complex is formed in a mixture of hydrochloric and chromic acids (Z. physik. Chem., 1903, 45, 584). Further experiments along similar lines show that sulphuric acid (4.49-N) and iodic acid (2.72-N) are isohydric (*i.e.*, the electric conductivity of a mixture of equal volumes of the two acids is the arithmetical mean of the conductivities of the individual acids), and therefore do not form a complex. With iodic and

chromic acids, on the other hand, a complex is formed, since solutions of these acids which are isolytic with 4-49-N-sulphuric acid are not isohydric with each other. Complexes are probably formed also in mixtures of phosphoric acid with sulphuric acid and with hydrobromic acid, since all attempts to prepare isohydric solutions of the two pairs of acids failed.—A. S.

Salt Formation in Solutions, especially of Indis-soluble Compounds. (*Pseudo Acids, Pseudo Bases.*) H. J. W. Brühl and H. Schroeder. *Z. physik. Chem.*, 1905, 51, 1—18. (See this J., 1904, 1242).

The authors show that as in the case of the alkyl esters of camphocarboxylic acid (*loc. cit.*), the formation of the sodium salt of acetoacetic ester from the ester itself, is associated with a transformation of the ketonic ester, $\text{CH}_3\text{CO}\cdot\text{CH}_2\cdot\text{COOC}_2\text{H}_5$, into the enolic oxygen salt, $\text{CH}_3\text{C}(\text{ONa})\cdot\text{CH}\cdot\text{COOC}_2\text{H}_5$. It is also shown that no formation of an addition compound of sodium acetoacetic ester with sodium ethylate takes place. A. S.

Educational.

LIVERPOOL UNIVERSITY.

Mr. E. K. Muspratt, President of the Council of Liverpool University, has offered to provide for an extension of the chemical laboratories, at an estimated cost, including equipment, of £10,500.

New Books.

REPORT OF THE DEPARTMENTAL COMMITTEE APPOINTED BY THE BOARD OF AGRICULTURE AND FISHERIES TO INQUIRE INTO AND REPORT UPON THE WORKING IN GREAT BRITAIN OF THE FERTILISERS AND FEEDING STUFFS ACT, 1893, WITH COPY OF MINUTES APPOINTING THE COMMITTEE. 1905. Price 4½d.

This Report contains Copy of Minutes appointing the Committee, with names of members, and it fills 38 pages, and is subdivided as follows:—Analysis of the Evidence, (i) Administration of the Act. (ii) Causes of Inefficiency of Act. (iii) Deficiencies in Safeguards to Purchaser. (iv) Deficiencies in Safeguards to Seller. (v) Miscellaneous.

MINUTES OF EVIDENCE TAKEN BEFORE THE DEPARTMENTAL COMMITTEE APPOINTED BY THE BOARD OF AGRICULTURE AND FISHERIES TO INQUIRE INTO AND REPORT UPON THE WORKING IN GREAT BRITAIN OF THE FERTILISERS AND FEEDING STUFFS ACT, 1893, WITH APPENDICES AND INDEX. Wyman and Sons, Ltd., Fetter Lane, London, E.C. 1905. Price 2s. Purchasable through any bookseller, or from Wyman and Sons, Ltd., Fetter Lane, E.C., and 32, Abingdon Street, Westminster, S.W., or of Oliver and Boyd, Edinburgh, or E. Ponsonby, 119, Grafton Street, Dublin.

GOVERNMENT blue-book, containing 167 pages of evidence, &c., and a series of 36 Appendices, filling 63 pages.

TABELLARIISCHE ÜBERSICHT ÜBER DIE KUNSTLICHEN ORGANISCHEN FARBSTOFFE UND IHRE ANWENDUNG IN FÄRBEREI UND ZEUGDRUCK. VON DR. ADOLF LEHN. Zweiter Ergänzungsband, Erste Lieferung. Julius Springer's Verlag, Berlin. 1905. Price M.6.

This Part I. of the supplementary volume of Dr. Lehn's work, the first edition of which received full notice in this J., 1903, 284, has just appeared. It is of quarto size, and contains a brief preface, table of contents, and illustrated tables filling 16 pages. There follows a column for testing

the colours for fastness on the fibre, and another for testing and discriminating the colours themselves on the and finally one of methods for systematically applying the colours with or without mordants to the fibre I. Wool; II. Silk; III. Cotton and Linen; and IV. An additional scheme is added of printing recipes Wool and Silk; II. Cotton (Linen); and III. Jute, after a list of abbreviations of the names of firms sent, including both British and American, the themselves follow, commencing with 1 and 2, represent the AZOXY DYESTUFFS, and like all the others are illustrated with dyed specimens. Then follow AZO DYESTUFFS; the Monoazo dyestuffs being sent in Tables 3 to 27, and the Disazo DYEST primary, Table 28; secondary, Tables 29—32; Disazo dyestuffs from Diamines, Tables 33—47.

THE BREWING INDUSTRY. By JULIAN L. E. Methuen and Co., 36, Essex Street, London, W.C. Price 2s. 6d. nett.

SMALL 8vo volume, containing 173 pages of matter with 28 illustrations, and an alphabetical The matter is subdivided and treated in the following groups:—I. Historical. II. Barley, Malt and Mal substitutes. III. Hops. IV. Water. V. Preparation Beer Wort. VI. Production of Beer from Beer VII. Brewery Operations and the Duties and Qualifications of a Brewer. VIII. Licensing and Tied Houses IX. Present Position and Future Prospects of the Industry in the United Kingdom.

LES INDUSTRIES INSALUBRES. Rapports sur les dangers et les moyens de les Prévenir, particulièrement dans l'Industrie des Allumettes et celles qui fabriquent ou emploient des Couleurs de Plomb. Par A. T. Bassia; E. P. Bérard, la Commission de Reformas Sociales à Madrid; Laurent Dechesne; E. M. Dementieff; Dr. H. Rauschenbach, &c., &c., and G. H. Wood. Published in the name of the International Association for the legal protection of Workpeople. Preceded by a Preface by Prof. ETIENNE BAUER, Directeur de l'Internat. du travail. Gustave Fischer, Jena, 1905. Price 10 Frcs. A. Francke vorm. Schmid and Fr. Berne; Le Soudier, 144/76, Boulevard St. Germain, Paris.

8vo volume, containing 438 pages of subject matter with alphabetical Indexes of names and subjects. The following are the leading subjects treated of:—I. Introduction by Prof. E. Bauer. The struggle with the danger of Phosphorus in the Industries (A. Hölzer). The Safety of White Lead (Th. Sommerfeld). Lead and Phosphorus Poisoning in the Austrian Industries (H. Kaup). Critical Examination of Lead and Lead preparations with regard to Industrial Hygiene (Stenroos). Insanitary Industries of Belgium (H. Vandevelde). Responses to Inquiries from the International Office of Labour (Laurent Dechesne). Insanitary Industries of Match Manufactures of Spain. Report on the measures regulating Labour in the Insanitary Industries of France. Match and Lead Manufacture, and Manufacture of Compounds, in France (Leclerc de Pulligny). Injurious Trades in Great Britain (G. H. Wood). Match manufacture in Japan (Matsuzaki); New Zealand (E. Trevelyan); Victoria (H. Ord); Greece (T. Bassia); Hungary (A. C. Kiaer); Roumania; Russia (E. Dementieff); Sweden (A. Raphael); Switzerland (H. Rauschenbach), &c., &c. Insanitary Industries in all the foregoing countries are also reported.

MINERAL OILS AND SPIRITS: RESTRICTIONS ON THE IMPORTS INTO AUSTRALIA OF —.

U.S. Cons. Rep. No. 2192, Feb. 25, 1905.

A proclamation issued by the customs department of India, declares the restrictions under which mineral oil spirits may be imported into the Commonwealth. The federation, each state of Australia had its own laws regarding the importation of the oils and referred to, and the proclamation, which is to take effect from April 1, 1905, provides that the flashing of mineral oils and spirits shall be uniform for the Commonwealth.

PROCLAMATION OF THE AUSTRALIAN CUSTOMS DEPARTMENT.

1. No mineral oil shall be imported as kerosene unless its flashing point of 73 degrees Fahrenheit or over.
2. All mineral oil and all productions therefrom, and mixtures containing mineral oil which has or have flashing point of under 73 degrees Fahrenheit shall, for purposes of this proclamation, be deemed to be mineral spirits.

3. No mineral spirits shall be imported unless contained in vessels so constructed as not to be likely to be damaged in handling or to become defective or insecure being conveyed, or to allow the mineral spirit to leak or to be accidentally opened, and unless such vessels shall be plainly marked with the name of their contents, "naphtha," "benzine," "benzoline," or "gasoline," or as the case may be, together with the words "highly inflammable."

4. In this proclamation the words "flashing point" mean the degree of temperature at which the mineral oil spirits give off an inflammable vapour upon tested by the "Abel-Pensky" test apparatus, or by other method as the minister from time to time may direct.

X.—METALLURGY.

MINERAL RESOURCES OF INDIA.

Times, March 12, 1905.

It is stated that American mining experts have established the existence in the Rajpur district of the Central Provinces of quantities of a rich iron ore. A company has been formed at once for the exploitation of this field. The recently published review, by Mr. T. H. Holland, Director of the Geological Survey of India, of the last six years progress in the development of Indian mineral resources, is the first under the system, adopted in 1898, of making a series of years instead of merely with the output of a single year. During these six years the total output has risen in value by 44·37 per cent.; the total scarcely touches £5,000,000 for minerals, including which trustworthy statistics are available, and has, on an average, imported annually ten millions' worth of minerals and mineral products which exist, or are produced, in the country. This figure does not include such things as hardware, porcelain, railway materials, or many other articles manufactured from minerals which are known to be present in large quantities in India. Four-fifths of the value of the mineral output is accounted for by gold, coal, and petroleum. These, as salt, which accounts for a large portion of the output, being one-fifth, are all won with comparative ease, and assumed by direct process, and are workable at a cost without consideration of the value of by-products. Minerals as rubies, mica, and manganese ore, which, at present, go to make up almost the whole balance of mineral output, are at present worked solely for export. Iron represents but a trifling value.

The review lays special stress on the intimate relationship in all countries between various chemical and metallurgical industries, on their dependence one upon another, and on the consequent necessity for their simultaneous development. Take for instance the case of copper sulphides. To work these for the metal alone is rarely profitable, but the situation is saved by the sulphuric acid which can be simultaneously produced in the process of extracting copper. Sulphuric acid, in turn, is dependent for its value on the demand created by innumerable other industries to which it is essential. So far, India has had to import all her sulphuric acid, and practically all her copper. Manganese ore is another instance. Its production in India dates from only 12 years ago; now the output is second only to that of Russia—a bad second, it is true, but the deposits are of very high value. The principal application of this mineral is to the manufacture of steel, which is still in its early infancy in India. In the absence of local demand, the manganese miners are compelled to export their ore to the steel works of Europe and America. This they can afford to do only with the best of the ore, and the cost of freight even then leaves but half the European market value for division between the producers and the railways carrying ore to the coast. India is again out of pocket by the freight of the steel which brings back, in its utilised form, some of this manganese. Aluminium is yet another case in point. There are in India vast quantities of laterite, resembling bauxite. The cost of freight prohibits export of the mineral, which can be profitably used only by extraction of aluminium at the quarries. For this process caustic soda is requisite. That substance is not at present made in India, though it easily might be, provided there were a demand for it, as well as for its by-product chlorine. The prime mover in most of these economic cycles is sulphuric acid. There seems no doubt that it could be produced in India more cheaply than it can be imported. When once this is accomplished, not only will the imported article be displaced, but fresh industries, depending for their profitable working on cheap sulphuric acid, will spring up, increasing the demand and still further cheapening the cost of production.

The Barakur ironworks, operating in the vicinity of the great coalfields of Bengal, have at last succeeded in producing some 500 tons a week of steel which is said to bear comparison with any produced in Europe or America. The new project, to which reference has been made, contemplates more than the mere working of the iron ores of Rajpur, an operation which will be facilitated by the fact that direct railway communication exists with the Bengal coal mines, as well as with those of Warora in the Central Provinces and Umaria in Rewah. Simultaneously with the new demand for coke for the blast furnaces which are to be set up, arrangements are proposed to be made for its preparation at the coalfields by the most modern methods.

Another branch of industry contemplated by the promoters of the new scheme is the manufacture of sulphuric acid from the deposits of copper sulphide, which are asserted by the Geological Department to abound in the Central Provinces.

This, as has already been said, will at last make possible the profitable production of copper, for which there is a great demand in India. Increased production of coal will enable India to dispense with the import of coal tar. The manufacture of steel will create a local market for the manganese ore of the Central Provinces, of Bombay, and of the Madras coast, thus enabling even the inferior ores to be utilised, and retaining for the producers the whole market value of the commodity.

MINERAL DISCOVERIES IN INDIA.

Chem. and Drug., March 4, 1905.

The chromite deposits lately discovered in British Baluchistan are now being opened up for export, 1,516 tons having been raised in the first six months of 1904. The manganese industry in the districts of Nagpur, Bandara, and Balaghat is yearly attaining to considerable propor-

tions, giving at the present time employment to several thousands of persons. An abundance of tin is easily accessible parts has been discovered in Tenasserim, Burmah.

BESSEMER STEEL INGOTS AND STEEL RAILS: U.S. PRODUCTION OF —, IN 1904.

Bd. of Trade J., March 2, 1905.

The "Bulletin" of the American Iron and Steel Association for February 15 publishes statistics, received direct from the manufacturers, of the production of Bessemer steel ingots and castings in the United States in 1904; also of Bessemer steel rails by the producers of Bessemer steel ingots.

The total production of Bessemer steel ingots and castings in 1904 was 7,859,140 tons, against 8,502,829 tons in 1903, a decrease of 733,689 tons, or over 8.5 per cent. The production in 1902 (9,438,363 tons) was the largest hitherto recorded.

The production of all kinds of Bessemer steel rails by the makers of Bessemer steel ingots in 1904 was 2,084,438 tons, against a similar production in 1903 of 2,873,228 tons, a decrease of 788,790 tons. The maximum production of Bessemer steel rails by makers of Bessemer ingots was reached in 1902, when 2,876,293 tons were made.

The total production of rails in 1904 will include rails made from open-hearth steel, rails rolled from purchased Bessemer blooms, crop ends, and "seconds," and rails re-rolled or renewed by non-producers of Bessemer steel ingots, and iron rails. The total from all these sources in 1903 amounted to 119,249 tons, of which quantity 15,054 tons were open-hearth steel rails and only 667 tons were iron rails. In 1904 the total from these sources will amount to about 200,000 tons, making the total rail production for that year about 2,300,000 tons.

In 1904 the United States exported 414,845 tons of steel rails and 1,405 tons of iron rails, and imported 37,776 tons of iron and steel rails.

XII.—FATS, FATTY OILS, Etc.

WAX, JAPAN. — U.S. CUSTOMS DECISION.

Feb. 14, 1905.

Wax from Yokohama, which on analysis was shown to be Japan wax of vegetable origin, has been declared free of duty as "vegetable wax," under paragraph 695 of the present tariff. The assessment of duty at $\frac{1}{4}$ cent per lb. as "tallow" was overruled.—R. W. M.

XIII. B.—RESINS, VARNISHES, Etc.

NINGPO VARNISH (LACQUER).

U.S. Cons. Rep. No. 2194, Feb. 28, 1905.

"Ningpo varnish" is made from the sap of the "varnish tree" (*Rhus vernicifera* or *Vernix vernicia*), which grows very extensively in western and south-western China. The sap is gathered in the interior and brought to Huichoum, in the southern part of Anhui Province, where it is refined. It is sold by the retailer in the raw or pure state—that is, the pure, refined sap, and in the prepared form, which is a mixture of the refined sap with certain proportions of "wood oil." It is in the proper blending of these that the skill of the varnisher is shown, as the colour desired, the wood to be varnished, moisture of the atmosphere, and temperature are conditions that enter into the problem. The uses of the varnish are manifold. It is particularly adapted to floors, tables, cabinets, and such articles as are in constant use. It is also excellent for furniture of all kinds, as it does not sear easily and may be scrubbed with boiling water without the slightest injury to the very high polish of which it is capable.

The greatest drawback to its use is the danger of "lacquer poisoning" to the workmen who use it. This is similar to "ivy poisoning," and when the sap is fresh is regarded as rather dangerous. Once the varnish is dry there is no danger whatsoever. It may be used in any climate that has a rainy season or wet weather. The

varnishing is always done during the wet season, and allowed to dry slowly as the moisture of the atmosphere decreases.

The market value of the pure sap, after refinement about 1.15 dols. Mexican coin per catty (about 1 lb.), while the mixed varnish may be had for 0.50 per catty. It may be mixed ready for use before shipment and does not deteriorate when once it has been prepared. About a hundred years ago the Ningpoes a monopoly of the varnish trade; but they have no it to the Huichau firms. Practically all the varnish at the present time comes from Huichau, as its mon depends on a knowledge and skill which the Hu people seem to be able to guard most effectively.

The supply of the crude sap would seem to be unlimited as the trees from which it is derived are found in abundance in all the middle western and south western provinces. With proper methods of gathering and refining the sap, it should be made one of the most profitable industries of China.

XIV.—TANNING; LEATHER; GLUE, Etc.

MANGROVE BARK INDUSTRY OF MOZAMBIQUE

Bd. of Trade J., March 9, 1905, 459.

Extensive forests of mangroves are found throughout all the bays, estuaries, and river mouths of East Africa and are composed of bushy, evergreen trees and shrubs. In certain localities these are found to be extensively intermixed with a plant probably inaccurately designated as the "White Mangrove." These trees grow thick on the coasts at all points accessible to tidal influence and propagate themselves with astonishing rapidity; some places the trees are so thickly produced that well nigh impossible for a man to push his way through them. The wood of the red mangrove is hard, durable, much used for building purposes, and said to be impervious to the attacks of white ants and other destructive agencies.

The quantities of mangrove bark exported from Mozambique, Parapat, Ibo, Porto Amelia (Pemba Bay) and Palma during the past year are reported as follows:—

Mozambique (to end of October, 1904), 1,725 tons; Parapat, 1,080 tons; Ibo, (about) 5,000 tons; Porto Amelia, 2,300 tons; Palma, 2,000 tons; total, 13,105 tons. Of the exports from Mozambique, 1,655 tons went to Germany, 65 to British Possessions, and 5 tons to the United Kingdom. The whole of the shipments from Parapat found their way to Hamburg, whilst although considerable quantities are known to have been despatched both to the United States and to Russian ports on the Baltic from Ibo, Port Amelia, and Palma, the actual figures in relation to the respective quantities are not available. In addition to the quantities mentioned a large amount of mangrove bark was, at the end of 1904, lying in the various ports awaiting collection by the coasting steamers.

The value of this export in the various European markets at the end of 1904 fluctuated between 40s. and 62 10s. per ton. The demand in Germany was said to be somewhat on the decline, but that in Russia and the United States continued firm. Freight to Hamburg is about 32s. per ton, whilst cost of collection, drayage, outlay for sacks obtained from India, as also the duty of 2 per cent., may be reckoned as amounting in the aggregate to between 20s. and 30s. for the same quantity.

XVI.—SUGAR, STARCH, GUM, Etc.

SUGAR IN EUROPE.

U.S. Cons. Rep. No. 2189, Feb. 21, 1905.

Owing to a very dry summer the sugar-beet crop in Europe is smaller than it has been for several years in spite of an increased acreage, the total crop is about 5 per cent. less than it was in 1903. While Europe produced 5,772,000 tons of raw sugar in 1903, the 1904 production will not exceed 4,650,000 tons, and the estimates of

best European authorities are even below this. Various sugar-producing countries of Europe may be divided into exporting and non-exporting, or treaty and non-treaty countries. The former, all parties to the Brussels Convention, consist of Germany, Austria-Hungary, Belgium, and The Netherlands. Their aggregate production of raw sugar in the current season is estimated at 60,170 tons. As these countries produced 4,208,996 tons last year, their loss amounts to nearly 850,000 tons. Reductions made in customs and internal duties have helped, in the various treaty countries, an increase in the consumption of sugar ranging from 15 to 30 per cent, and this has diminished correspondingly the quantity available for export. The non-treaty countries—Russia, Sweden, Spain, Denmark, and Roumania—the estimated production in the present season is 1,262,570 tons. Compared with the year 1903-4, there is a loss of over 300,000 tons, this loss (except in the case of Russia, which is still almost self-supporting), must be made up by increased imports. The following table gives estimates of the quantities of sugar produced during the current season, together with quantities produced during the season ended September 30, 1904:—

Production of beet sugar in the several European countries in 1903-4 and 1904-5.

Country.	Production of 1903-4.	Estimated production of 1904-5.
Exporting.	Tons.	Tons.
Austria-Hungary	1,929,415	1,518,070
Belgium	1,158,800	914,800
Denmark	794,431	614,300
Germany	202,850	179,100
Netherlands	123,500	133,900
Total	4,208,996	3,360,170

Only the Netherlands and Denmark made slight gains, while all the other countries sustained losses ranging from 1 to 50 per cent.

TOTAL BEET AND CANE SUGAR PRODUCTION.

On September 1, 1903, when the Brussels convention came into effect, the world's surplus of sugar was, in round numbers, 2,000,000 tons. At the beginning of the present season this surplus was reduced to 1,627,000 tons. Adding to this the estimated production of the year 1904-5, namely, 4,623,000 tons of beet sugar and 6,900,000 tons of cane sugar, we have for the current year a total of 12,950,000 tons available for consumption. As the world's consumption in the year ended August 30, 1904, was somewhat in excess of 13,000,000 tons, it follows that sugar will have to be used somewhat more sparingly in 1905 than it was in 1904, and this explains the recent sharp rise in the price of the article.

It is, however, not likely that the present prices will continue for more than eight or ten months. There will be, in consequence of the high price which sugar now commands, not only a decrease in the consumption of the article, but also a large increase in the acreage of beets and cane planted; and a propitious season may cause prices to be as low or even lower next autumn than they were at the time of the Brussels convention.

Country.	Production of 1903-4.	Estimated production of 1904-5.
Non-exporting.	Tons.	Tons.
Russia	1,160,660	945,370
Sweden	107,241	88,200
Spain	90,000	85,000
Italy	140,000	80,000
Denmark	47,000	48,000
Roumania	18,000	16,000
Total	1,562,901	1,262,570
Grand total	5,771,897	4,623,740

XVII.—BREWING, WINES, SPIRITS, Etc.

FUSEL OIL; GERMAN —

Chem. and Drug., March 4, 1905.

Exports of German fusel oil to the United States for 1901 amounted to 223 metric tons, in 1902 to 260 and in 1903 to 342 tons. During the first eight months of 1904, however, only 57 tons was exported, against 286 tons during the same period of 1903. There are no available statistics showing the total production of fusel oil in Germany, but nine-tenths of the quantity produced is absorbed by the United States, the remainder going to Great Britain. The trade in Germany is concentrated in comparatively few hands, principally in Hamburg, and Berlin. A few years ago fusel oil was looked upon as practically a waste product, but in the United States it is used in the manufacture of dynamite explosives, and to a less extent in varnishes and lacquers.

ALCOHOL IN FRANCE DURING 1904.

Z. Spiritusind., 1905, 28, 92.

The official statistics for 1904 as compared with 1903 are as follow:—

	1904.	1903.
(1) Industrial distilleries:—	Hl.	Hl.
From Grapes	88,509	26,810
Fruit	22,175	2,274
Grape marc	70,922	21,796
Grain, &c.	380,710	352,928
Beetroot	992,149	926,159
Molasses	626,722	670,969
Other materials	175	207
Total production	2,181,362	2,001,143
(2) Small distilleries (estimated):—		
From Grapes	247	3,398
Fruit	411	6,233
Grape marc	75,228	36,266
Total production	75,886	45,897

Used in manufactures	"	15,000	15,000	20,047	40,129	65,172	81,218
Used in drink	"	677,225	589,085	627,297	576,599	470,999	599,115
Per head	Number	6,373,922	6,436,653	6,698,810	6,326,219	6,393,403	6,961,248
Estimated consumption per head	Litres	10.62	9.15	9.37	8.45	5.37	5.73

Two industries which owe their existence to the release of methylated alcohol from duty, *viz.*, the production of ether and the manufacture of artificial silk, have already become important: the amount of alcohol used in these two industries in 1903 exceeded 40,000 hectolitres.

The following table shows the rapid increase that there has been in recent years in the amount of methylated alcohol used for industrial purposes consequent on relief from taxation:—

Year.	Alcohol Denaturated.	Duty Remitted.
	Hectolitres.	£
1896	4,811	8,383
1897	10,800	19,525
1901	21,367	68,628
1902	35,128	124,047
1903	60,172	319,223

The amount of alcohol applied to industrial uses in 1904 is estimated at 76,218 hectolitres, and the amount of tax remitted at £427,672.

The following table shows the chief industries in which alcohol is used, and the amount used in the past two years in hectolitres:—

Class of Industry.	1902.	1903.
	Hectolitres.	Hectolitres.
Vinegars	7,918	12,585
Varnish	2,237	2,329
French polish	1,976	2,052
Other varnishes	1,113	1,219

Artificial silk	6,568	14,783
Antiseptic cotton wool	171	270
Pegamoid tissues	319	20
Felt and hats	116	106

XIX.—PAPER, PASTEBOARD, Etc.

NYLONITE AND CELLULOID.

Chem. and Drug., March 11, 1905.

A memorandum, dated February 1905, has been issued by the Home Office (Form 828) dealing with the measures of precaution required in the storage and use of xylonite and celluloid. It is recommended that where large quantities are stored, fireproof rooms should be provided; where it is used, or temporarily stored, the material not in actual use should be kept in metal or other fireproof receptacles; that xylonite or celluloid shavings or dust should not be allowed to accumulate on the floors, but should be swept up daily and placed in receptacles of non-inflammable material, not in the sacks or wooden boxes now commonly employed for the purpose. The use of naked lights should be avoided as far as possible; where cutting or sawing of xylonite is done, the saw or other cutting instrument should run in water, or by other means be kept thoroughly cool; the shanks of tools used for boring the scales for table knives and forks should be of such form as to avoid friction caused by contact with the material bored; in addition to a supply of water, buckets filled with damping sand should be kept at hand in constant readiness in every shop in which xylonite or celluloid is being worked, in order that any accidental fire may be immediately smothered before it attains serious proportions.

WOOD PULP TRADE OF NORWAY.

Ed. of Trade J., March 9, 1905.

There is every probability of there being a considerable shortage in the supply of Norwegian timber and wood pulp during the current year. Up to the present time there has been scarcely any snow in Norway, and snow is an essential element for the transport of timber by sleigh to routes of communication. Consequently a great deal of timber has had to remain where it was felled

and the season is too far advanced for there to be prospect of its now being conveyed to the markets.

The weather throughout last summer and autumn also exceptionally dry, and there is great fear that the necessary water to drive the saw mills will fail during the present year. Even if rain were to fall now in abundance, the frozen condition of the soil in the mountains would prevent its absorption and retention. The outlook, therefore, for the timber, pulp, and wood fibre trade is far from reassuring.

XX.—FINE CHEMICALS, Etc.

SULPHURIC ETHER AND COLLODION FREE OF DUTY IN THE NETHERLANDS.

U.S. Cons. Rep. No. 2194, Feb. 28, 1905.

Sulphuric ether and collodion required in the preparation of photographic paper, and collodion required in the preparation of whal-bone are now exempted from customs dues on importation into the Netherlands. Regulations governing their free admission are as follows:

Article 1.—Sulphuric ether and collodion required in the preparation of photographic paper and collodion required in the preparation of whalebone shall be exempt from customs dues under the following regulations:—

Article 2.—Anyone desiring such exemption must address the minister of finance, stating the place in the factory is situated, the surveyor's section, an number of the factory and the quantity of each liquid estimated to be used annually. The minister of finance shall determine the quantity of material that annually be exempt from dues as well as the minimum of each importation.

Article 3.—On the importation of sulphuric ether and collodion in regard to which exemption is desired, must be made of such desire in the declaration prescribed by article 120 of the general law of August 26, 1900 (Official Gazette, No. 28.) To that declaration, subject to the deposit of security for the customs dues, a warehouse shall be attached mentioning the said desire. The quantity of the liquids to the factory shall be effected under the following regulations:

Article 4.—The importation to the factory shall be effected under the supervision of the officials of customs and excise, in whose presence the quantity of sulphuric ether shall be immediately mixed with 1 kilo. of acetone per 100 kilo., and the collodion with 2 kilo. of pure methylated spirits and 0.5 kilo. of acetone per 100 kilos. The officials shall make a statement on the warehouse respecting the imported quantity and the mixing. The materials required for the mixture shall be supplied by the tax collector at the manufacturer's expense.

Article 5.—The mixture shall be used for no other purpose but the preparation of photographic paper and collodion, and may not be removed from the factory.

Article 6.—The collector within whose district the factory is situated shall keep an account with the manufacturer of the quantity of sulphuric ether and collodion imported free from dues. In case more should be imported than the quantity in regard to which exemption from duties has been granted the waybill shall not be cleared for exportation, and the excess and the dues deducted from the security.

Article 7.—At the end of every year the party enjoying exemption shall tender the collector a written and signed statement of the quantity of sulphuric ether and collodion admitted free from dues and still on hand at the end of such period. This quantity shall be regarded as the first importation in the ensuing year, and as such shall be entered in the account referred to in Article 6. If such statement is tendered no new importation shall be allowed.

Article 8.—The officials authorised thereto by the minister are empowered within eight days of the expiration of the year to inspect the quantity of sulphuric ether and collodion in the factory, no matter whether the statement mentioned in the preceding article has been made or not.

Article 9.—On evidence of abuse or any attempt to evade the provisions of the provisions of this order, the minister of finance is authorised to refuse the manufacturer all further free importation of sulphuric ether and collodion.

ANOL AND MORRHUOL: U.S. CUSTOMS DECISION.

Feb. 14, 1905.

Following a decision of the United States Circuit Court of Appeals, the Board of General Appraisers overruled its assessment of duty on gaduol and morrhuol at 55 cents per lb., as "medicinal preparations in the preparation of which alcohol has been used," and decided them to be taxable at 25 per cent. *ad valorem* as "chemical compounds" under paragraph 3 of the tariff.—R. W. M.

Patent List.

—In these lists, [A.] means "Application for Patent," and [C.S.] means "Complete Specification Accepted."

Where a Complete Specification accompanies an Application, an asterisk is affixed. The dates given are (i) in the case of Applications for Patents, the dates of application, and (ii) in the case of Complete Specifications Accepted, those of the Official Journals in which acceptances of the Complete Specifications are advertised.

Complete Specifications thus advertised as accepted are open to objection at the Patent Office immediately, and to opposition within two months of the said dates.

—PLANT, APPARATUS, AND MACHINERY.

- 4271. Binder. Centrifugal extractors. [U.S. Appl., March 25, 1904.]* March 1.
- 4330. McNeil. Apparatus for separating liquids from vapours.* March 2.
- 4331. McNeil. Apparatus for separating liquids from vapours.* March 2.
- 4332. McNeil. Apparatus for separating liquids from vapours.* March 2.
- 4352. Liebenthal, Bieber, and Inhalatorien Ges., system Dr. Heryng. The conversion into gas or vapour and the distillation of difficultly volatile and other liquids.* March 2.
- 4426. Mundy, Broadley and Rhodes. Disintegrating, drying and mixing machine. March 3.
- 4522. Bicksey. Annular kilns. March 4.
- 4671. Scott. Evaporating pans. March 6.
- 4792. Simm. *See under II.*
- 5072. Ljungström. Centrifugal separators for liquids.* March 10.
- 5108. Crosfield and Markel. Separation of solids from liquids. March 11.
- 9355 (1904). Holl. *See under XVI.*
- 9516 (1904). Lennox. Evaporators for evaporating the liquid in brewer's wash, sewage, waste or spent dyes, &c., and concentrating the solids in the same. March 15.
- 12,253 (1904). Barnes and Tory. Pyrometers. March 8.
- 14,869 (1904). McWhirtir. Apparatus for heating, steaming, and chemically treating wood and goods of different kinds, and for drying such goods. March 15.
- 23,183 (1904). Wells. Drying apparatus. March 15.
- 25,796 (1904). Drojecki. *See under X.*
- 29,573 (1904). Lennox. Filters. March 8.

II.—FUEL, GAS, AND LIGHT.

- [A.] 4020. Torda and Bernald. Photometers. Feb. 27.
- " 4013. Smith. Suction gas producers.* Feb. 27.
- " 4044. Smith. Regulating air supplied to suction gas producers.* Feb. 27.
- " 4087. Sellars, Wallace and Capel. Gas generating plant.* Feb. 27.
- " 4291. Knops. Process for manufacturing artificial fuel. March 1.
- " 4352. Liebenthal, Bieber, and Inhalatorien Ges., system Dr. Heryng. *See under I.*
- " 4498. Broadhead. Gas purifiers. March 4.
- " 4792. Simm. Extracting moisture from peat and the like. March 8.

- " 2139 (1905). Jarvis and Jarvis. Composition of lubricants. March 15.

IV.—COLOURING MATTERS AND DYESTUFFS.

- [A.] 4359. Newton (Bayer und Co.). Manufacture of azo dyestuffs. March 2.
- " 4363. Imray (Meister, Lucius und Brüning). Manufacture of a red azo dyestuff and of lakes therefrom. March 2.

- [A.] 4647. Imray (Meister, Lucius und Brünig). Manufacture of preparations of indigo white. March 6.
- .. 4708. Hirschberger and Hoffa. A new base and new sulphuretted azo colours derived therefrom. March 7.
- [C.S.] 4997 (1904). Johnson (Badische Anilin und Soda Fabrik). Manufacture of azo colouring matters, and of intermediate products therefor. March 15.
- .. 9516 (1904). Lennox. *See under I.*

V.—PREPARING, BLEACHING, DYEING, PRINTING AND FINISHING TEXTILES, YARNS, AND FIBRES.

- [A.] 4163. Shepherd. Waterproofing composition. Feb. 28.
- .. 4211. Burdick. Methods of and apparatus for colouring or decorating fabrics, paper, and other materials. Feb. 28.
- .. 4222. Davies and Ewing. Applying colour to fabrics, or colour or paint to other surfaces for producing designs thereon. March 1.
- .. 4534. Denis. Apparatus for producing threads from collodion and recovering the solvents employed [Fr. Appl., March 5, 1904].* March 1.
- .. 4593. Roberts. *See under XI.*
- .. 4755. Linkmeyer. Manufacture of artificial threads. [Ger. Appl., June 8, 1904.]* March 7.
- .. 4761. Linkmeyer. Manufacture of lustrous threads of cellulose. [Ger. Appl., Aug. 26, 1904.]* March 7.
- .. 4765. Linkmeyer. Manufacture of lustrous cellulose threads. [Ger. Appl., Oct. 17, 1904.]* March 7.
- .. 4829. Armitage. The finishing of certain fabrics. March 8.
- .. 4947. Kühler. Method of and apparatus for producing mottled colouring effects in fabrics.* March 9.
- .. 4971. Walker. Compounds and processes for fire-proofing textile fabrics and the like.* March 9.
- [C.S.] 7745 (1904). Pope and Hübner. Engraved bowls or rollers for producing an improved reflecting finish on textile fabrics, paper, and other lamellar materials. March 15.
- .. 7790 (1904). Dawson. Wool washing and scouring machinery applicable for carbonising wool, &c., and for continuously dyeing and bleaching wool, cotton, and other fibrous material. March 8.
- .. 9323 (1904). Pease, Parker and Hustler. Washing, scouring, extracting, neutralising and dyeing machinery for wool and the like. March 15.
- .. 9455 (1904). Abel. (Act.-Ges. f. Anilinfabr.) *See under VI.*
- .. 9516 (1904). Lennox. *See under I.*
- .. 9787 (1904). Ellis. Machine for washing, bleaching, dyeing, or similarly treating hanks of yarn, slubbing, warps, and the like. March 8.
- .. 29,618 (1904). Rössler. Apparatus for dyeing textile fibres. March 8.

VI.—COLOURING WOOD, PAPER, LEATHER, ETC.

- [A.] 4211. Burdick. *See under V.*
- [C.S.] 7745 (1904). Pope and Hübner. *See under V.*
- .. 9455 (1904). Abel (Act.-Ges. f. Anilinfabr.). Process for dyeing furs, hairs, and leathers. March 8.

VII.—ACIDS, ALKALIS, AND SALTS.

- [A.] 4245. Schmatolla. Kilns for burning limes dolomite, and the like. March 1.
- .. 4334. Sanders. *See under X.*
- .. 4353. Niedenführ. Process of manufacture of nitric acid.* March 2.
- .. 4648. Russ. Method for increasing the chemical activity of chlorine. March 6.
- .. 4762. Johnson (Badische Anilin und Soda Fabrik). Manufacture of dehydrated or nearly dehydrated caustic alkalies.* March 7.
- [C.S.] 6143 (1904). Mills. Manufacturing salts of soda. March 15.
- .. 7452 (1904). Von Grätzel. Catalytic process of dehydrating acids. March 8.
- .. 26,790 (1904). Johnson (Deuts. Gold- und Silb.-Scheide Anstalt vorm Rössler). Manufacture of metallic perborates. March 8.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

- [A.] 4194. Boulton (Reiche). Process for manufacturing hydraulic binding substances or cements. Feb. 28.
- .. 4200. Klein. Refractory material for furnace bottoms, fire bricks and the like. Feb. 28.
- .. 4255. Schmatolla. *See under VII.*
- .. 4445. Love. Material for constructive and decorative purposes. March 3.
- .. 4693. Rogers. Method of applying pure calcium powder as an insulating covering.* March 7.
- .. 4733. Wynne. Production of a material for the manufacture of hydraulic cement. March 7.
- .. 5130. Prost and Michéy. Manufacture of non-inflammable materials. [Belg. Appl., March 14, 1904.]* March 11.
- [C.S.] 5712 (1904). Shedlock. Manufacture of asphalt. March 15.
- .. 5853 (1904). Brothers. Manufacture of plaster of Paris and apparatus therefor. March 15.
- .. 9769 (1904). Lefranc. Manufacture of artificial stone in imitation of marble or granite. March 15.
- .. 10,170 (1904). Grau. Manufacture of cement. March 8.
- .. 23,473 (1904). Gibbs. Art of decomposing refractory silicates. March 15.
- .. 27,991 (1904). Williams and Stauffer. Manufacture of firebricks, crucibles, refractory substances and the like. March 8.

X.—METALLURGY.

- [A.] 4052. Deister. Ore concentrators.* Feb. 27.
- .. 4334. Sanders. Treatment of galvanisers' waste products for the recovery of metal, and the fixation of other substances. March 2.
- .. 4395. Moss. Magnetic separators for ores. March 3.
- .. 4744. Draper and Hay. Almagamators. March 7.
- .. 5091. Cowper-Coles. Process of welding aluminium. March 11.
- .. 5144. Andrew and Bellis. Treatment of waste grade steels. March 11.
- [C.S.] 5648 (1904). Stringfellow. Treating blast furnace slag and utilising the products thereof. March 5.

- [C.] 6997 (1904). Zenzen. Production of iron suitable for the manufacture of malleable castings. March 15.
- 7935 (1904). Minnis. Method and apparatus for galvanising and coating metal sheets. March 15.
- 9928 (1904). Smallwood. Muffles or furnaces. March 8.
- 25,796 (1904). Drojecki. Reverberatory furnaces. March 8.

X.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

- A. 4100. Thompson (Decker Manufacturing Co.). Electrolytic apparatus.* Feb. 27.
4109. Wade. Galvanic batteries. Feb. 28.
4287. Marino. Secondary batteries. March 1.
4544. Cowper-Coles. Electrolytic manufacture of metallic wire or strip. March 4.
4545. Cowper-Coles. Electrolytic production of metallic strip. March 4.
4593. Roberts. To use electric currents so as to electrolyse baths made of different acids for the purpose of destroying all vegetable matter in wool, rags, and other fibres. March 6.
- 11,470 (1904). Atkins. Poles or electrodes of electrolytic apparatus or the like. March 15.
- 20,627 (1904). Bosquet. Method for the electrolytic manufacture of water jackets, casings, and the like. March 15.

X.—FATTY OILS, FATS, WAXES, AND SOAP.

- A. 10,466A (1904). Dreyman. Utilisation of fatty acid esters for alimentary fats, illuminating oils, and the like.* March 8.
4092. Krebitz. Process for the manufacture of insoluble soap and for converting same into soluble soda soap or potash soap. Feb. 27.
- 10,156 (1904). Hall. Method and means for removing oil and grease from sponge cloths, cotton waste, and all kinds of grease laden textile materials. March 15.

—PIGMENTS, PAINTS; RESINS, VARNISHES; INDIA-RUBBER, ETC.

(A.)—PIGMENTS; PAINTS.

4363. Imray (Meister, Lucius und Brüning). *See under IV.*
4646. Imray (Meister, Lucius und Brüning). Manufacture of red colour lakes. March 6.
- C. 9674 (1904). Johnson (Badische Anilin und Soda Fabrik). Manufacture of colouring matter lakes. March 15.
- 9861 (1904). Johnson (Badische Anilin und Soda Fabrik). Manufacture of colouring matter lakes. March 15.
- 12,512 (1904). Newton (Bayer und Co.). Manufacture of new colour lakes. March 15.
- 22,732 (1904). Kollinger. Manufacture of paint. March 15.
- 29,245 (1904). Ojeda and Quesdas. Copying inks. March 8.

(B.)—RESINS, VARNISHES.

- C.] 9975 (1904). Godfrey. Manufacture of linoleum. March 8.
- 9976 (1904). Godfrey and Linoleum Manufacturing Co., Ltd. Manufacture of linoleum. March 8.

(C.)—INDIA-RUBBER.

- [A.] 5154. Gubbins. Method of treating rubber waste. March 11.

XIV.—TANNING, LEATHER, GLUE, SIZE, ETC.

- [C.S.] 19,323 (1904). Petersen. Preparation for cleansing and dyeing skins, leather, and the like. March 15.

Official Notices.

COMMUNICATIONS

Authors of communications read before the Society, or any of its Local Sections, are requested to take notice that under Rule 43 of the Bye-laws the Society has the right of priority of publication for three months of all such papers. Infringement of this Bye-law renders papers liable to be rejected by the Publication Committee, or ordered to be abstracted for the Journal, in which case no reprints can be furnished to the author.

ANNUAL GENERAL MEETING, 1905.

The Annual General Meeting will be held in London in July next, and the proceedings will commence on Monday, July 10th. Full particulars will appear later.

SIXTH INTERNATIONAL CONGRESS OF APPLIED CHEMISTRY, ROME, 1906.

At a meeting of the Organising Committee of the Sixth International Congress of Applied Chemistry, held in Rome on March 2 last, Prof. E. Paterno in the chair, it was decided to divide the Congress into the same number of sections as was the case at Berlin in 1903. At the suggestion of the Presidents of foreign Committees, the date of meeting was fixed for April, 1906, during Easter week.

All communications with respect to the Congress should be addressed to the President, Prof. E. Paterno, Via Panisperna 89, Rome.

Changes of Address.

When notifying new addresses, members are requested to write them distinctly, and state whether they are temporary or permanent. Multiplication of addresses is also to be avoided as tending to create confusion. When sending subscriptions, the use of the form attached to the application helps in the verification of addresses, on which the safe delivery of the Journal depends.

MR. EUSTACE CAREY IN THE CHAIR.

METHODS OF TEMPERATURE INDICATION.

BY ERNEST J. BATY, B.Sc.

attempt seems to have been made to classify methods employed for indication of temperatures, so of which have been devised of recent years, for various purposes and for the extremely exact requirements of the research laboratory.

For exact work with the mercurial thermometer, several conditions are necessary. Though a fine capillary is required owing to the small expansion of mercury, it must be too fine, or a jerky motion of the mercury will be caused by friction in the mercury column, combined with the elasticity of the large bulb with thin walls, is essential for quick and accurate readings.

For temperatures above the range of the ordinary thermometer, nitrogen filled thermometers are used, containing this gas under high pressure, to prevent mercury boiling. The high boiling point liquid of sodium and potassium is also used, but for this class only can be used owing to the action of the ordinary soft glass.

The first pyrometers were designed for pottery works, for firing of clays requiring a carefully regulated temperature—Wedgwood's pyrometer consisted of a number of half-baked clay cylinders put into the furnace on pottery, and taken out one at a time till the contraction was produced, this denoting not so much that the temperature was correct, but rather that firing had been sufficiently high for a long enough

time measures temperatures by the appearance of certain tile: his table is as follows:—

Very dull red	525° C.
Dull red	700° C.
Bright red	800° C.
Cherry red	900° C.
Bright cherry red	1000° C.
Very deep orange red	1050° C.
Deep orange red	1100° C.
Orange red	1200° C.
Whitish	1300° C.
Brilliant white	1400° C.
Dazzling white	1500° C.
Blue white	1600° C.

pyrometers measuring the temperature of incandescent bodies by comparing the whiteness of their light with a standard may be used for temperatures between 1100° and 1900° C.

The Holborn-Kuhrbaum instrument, a telescope pointed to the furnace contains an electric lamp, the intensity is regulated by a resistance until the light is comparable to that of the furnace. A voltmeter and ammeter shows the electric energy supplied to the lamp, from which the temperature of the furnace is calculated. A second method on the same principle consists in comparing the luminosity of the medium with a standard and less bright light, the latter light being cut down by crossing Nicol prisms until the intensities seen at the end of the telescope are equal; the angle of the prisms then gives the temperature of the body examined.

The melting of alloys of varying composition was used to find whether the temperature attained a certain value; silver-gold and gold-platinum alloys were used in pieces about the size of pins heads, exposed in a furnace in a small cupel; these tests could only be used once owing to molecular changes in the alloys. The expansion of a metal rod has long been used, one being bedded in porcelain and the other moving through a train of levers and pinions. Guillaume found that a nickel steel containing 36 per cent. of

nickel has a practically negligible expansion (less than $\frac{1}{1000}$ of that of brass); it is likely to find use in pyrometers depending upon comparative expansion of metals.

When two metals of widely differing expansions are soldered on either side of a strip of soft metal, the compound strip thus produced tends to roll up on change of temperature; such a method is in use for testing the temperature in the blast main of iron furnaces, a pencil on a lever marking the temperature on a revolving drum.

A rough method of finding the temperature of the hot blast consists in taking out a plug from the goose-neck and finding how long it takes a piece of aluminium or zinc to melt in the issuing gas. A simple pyrometer consists of an iron bar inserted into a furnace wall and projecting on either side. A certain amount of cooling takes place before the heat arrives at the end of the bar, where a mercury thermometer gives approximate values.

This method has been replaced by air and water current pyrometers. Air current thermometers may be used for temperatures up to 4000° F. A pipe in two separated sections is inserted in the furnace and air is drawn in from outside into the lower section and after passing through the heated bulb returns through the upper section where it heats a mercurial thermometer. The outlet for the air being considerably above the inlet, a current of air is kept flowing in the one direction. A water current pyrometer on very much the same principle is in use at the porcelain works of Sèvres and Limoges.

Another method of measuring the temperature of the hot blast consists of an injector for gases. The hot gases passing through the first cone draw in and thoroughly mix with a proportional amount of cold air, the temperature of the mixture being within the range of a mercurial thermometer.

Thermopiles depend upon the increase in vapour pressure of liquids with rise of temperature. They consist of a tube three to six feet long, surmounted by a pressure gauge. For temperatures between 95° and 350° F. ether is the liquid used. Mercury is used for temperatures up to 1400° F.

For higher temperatures than these Lumy's pyrometers are in use; they depend on the dissociation pressure of limestone, according to the temperature, a mercurial manometer being used. Calorimetric methods are also employed.

Siemens' water pyrometer has its capacities adjusted so that the furnace temperature is read off directly on the scale of the thermometer of the calorimeter. Loss of heat in transit has been a grave objection to calorimetric methods; if, however, such exactness is needed, a carrier of copper or graphite may be provided for the mass of metal, heated up with it to the furnace temperature and removed only just before dipping into the calorimeter. Aniline is found to be rather more satisfactory than water for some calorimetric methods, owing to the larger rise in temperature produced in it as compared with water.

For laboratory experimenting on high temperatures, thermo-couples are largely used, the best combination being that of platinum and platinum-rhodium, containing 10 per cent. of the latter.

Holborn and Wein state that the readings of different thermo-elements may be expected to agree within $\pm 5^\circ$ C. at 1000°, whilst different observations of the same instrument may agree better than this.

There is a large number of thermo-electric pyrometers on the market, each of which has its own special merits: the junctions are in most cases of platinum and a platinum alloy for high temperatures, and of iron or copper and "constantan" for low temperatures, the voltmeter being always of the D'Arsonval type, this being the most sensitive. Temperatures registered by these instruments may be from refrigerating temperatures up to 1600° C., the reading of the galvanometer being usually directly in degrees.

The platinum resistance thermometer has already been fully described in this Journal.

DISCUSSION.

The CHAIRMAN asked, with respect to the Wedgwood clay pyrometer, if it was correct that a clay pyrometer

continued to shrink almost indefinitely by repeated exposures to a high temperature. Mr. Baty had also spoken about an alloy which he understood took two days to indicate the temperature.

Mr. BATY said the alloy that he mentioned had a very small expansion, and it might be used more on account of that for comparative purposes; he imagined that during the two days there was some alteration in the molecular constitution of the alloy.

The CHAIRMAN also alluded to a rough but useful method of indicating approximately the temperature of the interior, for example, of a cast iron pot, which it might be desired to keep as nearly as possible at 500° or 600° F. The pot would probably have a thick flange, which would be or might be exposed to the air. If a hole were drilled in that flange, and an ordinary mercury thermometer placed in the hole in contact with the metallic iron, the thermometer would give a sufficiently accurate indication from time to time of the temperature of the interior, and it appeared to him that that method of indicating temperatures might be further developed.

Mr. J. T. CONROY said at Widnes they had a fairly large experience of high temperatures. One of the first pieces of work he had to do there was to find out with some degree of accuracy the dissociation temperature of lime-stone. They had no accurate pyrometers in the laboratory at that time, so they constructed a pyrometer on the Siemens principle. He wound a platinum wire round a glazed porcelain tube, and found it most satisfactory at temperatures up to 600° C. Beyond that he found the instrument never went back to its zero point again. Shortly afterwards, Heycock and Neville published the results of their investigations with the Siemens pyrometer as modified by Callender, and described the instrument which Mr. Baty had shown them with platinum wire wound round mica plates and carefully compensated. At the same time they described the evil results which followed the contact of the platinum wire with the porcelain glaze at high temperatures, and gave the clue to his own difficulties. They had recently bought for the laboratory one of the instruments made by the Cambridge Scientific Instrument Company, and so far as their experience went, the instrument was accurate, sensitive and constant, but expensive to buy and likely to be expensive in repairs, because of the fragile nature of the porcelain covering tubes. He had also made one of the Le Chatelier "couple" pyrometers with platinum and platinum rhodium wires. That he found more satisfactory than the home-made resistance pyrometer, but it was not nearly so sensitive, although, as Mr. Baty had told them, provided no gases were allowed to act on the wires, the pyrometer was accurate in its readings and always went back to zero. For general works purposes they used a modified form of the Siemens calorimeter. Instead of using platinum they employed an iron vessel. The water was measured by filling a small tin vessel to the brim, and was then transferred to a leaden cup which served as calorimeter. The operation was simple, and only the thermometer breakable. For rough purposes and for medium temperatures up to 400° or 500° C., that instrument was very satisfactory. Of course the readings were not absolute, but they enabled the workman to always work his furnace under constant conditions, and they were very easily replaced.

The CHAIRMAN confessed that he believed these calorimeters which Dr. Conroy had referred to were good enough for almost all works purposes.

Dr. CONROY said they were not suitable for high temperatures, owing to the iron bolt becoming oxidised. If they used platinum, they might do quite as well for higher as lower temperatures, for approximate measurement.

Mr. J. BOYD said he had also experienced considerable difficulty in preserving the porcelain tubes, but he had found that that difficulty was partly overcome by wrapping the tubes in asbestos. He thought that the carburetting of metal was a very important point in connection with the electric pyrometers. The metals they used were platinum and platinum with 10 per cent. of iridium, and these became so altered after exposure to a high temperature that the instrument was no longer reliable.

Mr. E. J. BATY, in reply to the Chairman's question as to the shrinkage of the clay, said that he mentioned that

the Wedgwood pyrometer was used chiefly in pot furnaces, and it did not matter whether the clay contracted with continued heating. It was more for the coils, the chief difficulty in the variation of temperature being that the tile would contract more downwards across. With tiles, of course the pattern must be expanded square. He mentioned the measuring by the iron very shortly, because he had not heard of any practical applications of it. A very small amount of impurity in the platinum appeared to produce these molecular variations, and he believed the platinum for all resistance thermometers was supplied from one melt.

Manchester Section.

MR. J. CARTER BELL IN THE CHAIR.

AN IMPROVED METHOD OF INDIGO TESTING

BY J. GROSSMANN, PH.D., F.I.C.

On the 31st December, 1897, I read before this Society a paper on indigo testing by permanganate. Prior to that date, in June of the same year I had published some notes on Indigo testing in the Journal of the Society of Dyers and Colourists, in which I brought down the bibliography of the subject from 1885 to the date of publication, and pointed out that an enumeration of methods up to 1885 could be found in the paper published by Mr. Christopher Rawson in that year. Since that time a number of methods, partly new, and partly modifications of the old methods have been proposed, abstracts of which may be found in the following numbers of the Journal of the Society of Chemical Industry:—J., 1896, p. 1; J., 1897, p. 938; J., 1898, p. 495; J., 1898, p. 609; J., 1899, p. 251; J., 1899, p. 712; J., 1899, p. 302; J., 1900, p. 100. Also E. Knecht, Journ. Soc. Dyers and Colourists, 1899, p. 100.

Generally speaking, all the methods which have been proposed for the testing of indigo may be divided into five classes.

1st. Those methods in which the indigotin is extracted by substances in which it is soluble, and after purification weighed as pure indigotin.

2nd. Methods in which the indigotin is sulphonated, the sulphonic acid determined volumetrically by oxidising agent.

3rd. Methods in which the indigotin is sulphonated, determined by the addition of substances which react quantitatively to a leuco indigo compound.

4th. Methods in which indigo is reduced and separated as leucoindigotin and oxidised to indigotin.

5th. Methods in which indigotin is determined gravimetrically.

The extraction methods have the great disadvantage that only small quantities can be dealt with for an analysis, and that none of them yield the indigotin at once in a pure state that it could be directly weighed; this applies to the methods mentioned under 4 and 5. Moreover, the time taken up for an analysis is considerable, the manipulation required of a delicate nature which requires considerable and almost continuous attention, the methods which depend upon the sulphonation of indigo and subsequent titration by oxidising or by reducing agents have therefore been found most suitable for commercial valuation, and I have pointed out in my communication that of all the methods which have been proposed those worked out by C. Rawson, and published in 1885, are the best and most convenient, and for practical purposes, there has been no better method than the one proposed by Rawson of salting out the pure indigotin, and testing it with permanganate. The drawback to that method has been that the salting out takes several hours, the filtration of the sulphindigotate is

does not readily filter, and some of the sulphindigo remains in the filtrate in solution, and has to be allowed a correction which is more or less arbitrary. In a published in 1899, C. Rawson proposed an improvement of his method by adding chloride of barium to the solution of the sulphonated indigo for the purpose of mechanically throwing down any impurities. No doubt this method is an improvement as far as the time required for an analysis is effected by it, but is questionable whether it will affect a certain class of impurities in the indigo which become sulphonated, and are not thrown down by the sulphate of baryta.

The method which I wish to lay before you to-night, which was worked out by me in the year 1891, which has been used in my laboratory since then, which I have found very reliable. I have tested thousands of samples by it, and have been on several occasions checked by Indigo brokers who have sent me a series of samples which I have previously tested for without my knowing that they were duplicates, in each case the results were identical to those which have received from me before. The principle of the method is based on the fact that the impurities in the indigo are only soluble as long as the solution is neutral. If the solution is neutral, these impurities fall out and are carried down along with the insoluble precipitate.

I form in neutralising the solution; and the way in which I proceed is as follows:—

1 gm. of indigo is finely ground with glass powder mixed with 20 c.c. of strong sulphuric acid of 45 sp. gr. It is heated for an hour at 90° C., then transferred into a litre flask containing some water and the flask is filled up to the mark with water. At this point I follow Rawson's instructions. I now add to my own method, which consists in placing 1 c.c. of this solution in a 500 c.c. flask, and gradually adding a sufficient quantity of pure calcium carbonate, is about 6 gm. to the solution. The flask is filled up to the mark and well shaken; after the calcium sulphate and the impurities which it has carried down have subsided, the liquid is filtered, and 249 c.c. corresponding to 250 c.c. with an allowance for the space occupied by the precipitate are measured into a porcelain beaker; a few centimetres of diluted sulphuric acid, and the solution may be titrated in the usual manner with permanganate of potash.

The solution obtained by treating indigo in this manner, requiring it for titration has the great advantage that it is a pure solution which may be used either for an oxidation-reducing test. It may, moreover, be used for a test or for a colorimetric test. It, therefore, does not depend upon the permanganate method, but may be used as a preliminary preparation for nearly every kind of analytical work proposed for the valuation of indigos, with the exception of those which are based on the estimation of indigotin by solvents, direct reduction, or oxidation. The method has the drawback which all estimating methods have of determining the indigo as indigotin; but as a rule, with the exception of special make of indigo, the quantity of indigo rubine or aniline indigos is exceedingly small.

I have not had an opportunity of checking my method on samples of Java indigo containing the yellow colouring which Rawson found in them, nor have I been able to determine the accuracy of my method in the case of artificial indigos containing impurities arising from their mode of manufacture, which will be most likely of a different nature to those occurring in natural indigo. I trust others will take up this line of investigation, and ascertain how far my method will apply in these cases.

In view of the extended use which artificial indigo is now making, and considering the fact that the sulphonating of indigo both in the case of artificial and natural indigo often give wrong results in such cases where indigo was contaminated with certain aniline colours which can be separated, such as aniline blue, &c., every sample of indigo of which the original source is not authenticated should be qualitatively examined before sulphonating by it with alcohol or other solvents which do not act on indigo. But as regards those cases the fault is one which is adherent to all methods which depend upon

previous sulphonation and subsequent oxidation and reduction, and is not one which is peculiar to my method.

I can thoroughly recommend my method as being one which is exceedingly quick and gives most concordant results. A test can be made in two hours from the time that the sample has been ground, and as it requires very little manipulation, half a dozen or more tests can be conveniently carried on at the same time. The solution of indigotate which is obtained after neutralisation with calcium carbonate is of extremely pure tint, and can, therefore, be most conveniently used either for dyeing out tests or for colorimetric determinations.

DISCUSSION.

Dr. GERLAND thought to sulphonate at 90° might be at too high a temperature. He asked Dr. Grossmann whether he had tried lead acetate as a precipitant for impurities, and expressed his hope that Dr. Grossmann's method of neutralising the solutions of indigo with calcium carbonate would overcome the great difficulties which had stood in the way of a quick and reliable test for indigo up to the present.

Professor KNECHT said he thought it might be taken for granted that Rawson's original salting out process was now obsolete, the far more convenient and rapid barium chloride process of the same chemist having taken its place. With regard to Dr. Grossmann's proposal to use calcium carbonate for precipitating the impurities from the solution, he would like to ask in the first instance whether any of the indigotin was mechanically retained by the calcium sulphate. It would further be interesting to know to what volume the lecturer diluted his indigo solution for titration, what strength of permanganate he used, and what factor he adopted for calculating the amount of indigotin present. It was well known that the factors given by Rawson and by the Badische Co. respectively differed materially from each other, and that they were neither in accordance with the theoretical value. It was not quite clear to him whether the lecturer actually filtered his solution from the calcium sulphate, or whether he decanted an aliquot part of the clear liquid after allowing time to settle. In the former case, the filter paper might absorb some indigo, and a slight correction would then be necessary. The lecturer had given 90° C. as the temperature used for sulphonating. He wished to point out that there was now a tendency to use for sulphonating temperatures below 90°, and to correspondingly increase the duration of the sulphonating process. Although he could not say from actual experience that a temperature of 90° would cause any loss in indigo through oxidation, he had ascertained in a series of experiments on pure indigotine that at 100° there was an actual loss amounting to about 1 per cent. per hour. With regard to his own process of estimating indigo by reduction with titanous chloride in tartaric acid solution, he had pointed out in a paper read before the Society of Dyers and Colourists that it gave accurate results on pure indigotine, but that the impurities present in commercial indigos so obscured the end-reaction that the process was rendered valueless for industrial purposes. He would gladly adopt the suggestion of Dr. Grossmann to try the effect of his calcium carbonate process on the reduction method.

Mr. BARNES also laid stress upon the importance of proper sampling.

Dr. FEILMANN wished to know whether indigotin sulphonate was carried down by the sulphate of lime.

Dr. GROSSMANN, in reply to Dr. Gerland, said that in sulphonating he had followed the careful work which Rawson had done, and accepted his method. In fact, up to the point where he added calcium carbonate to the solution of indigo he had adopted exactly the method which Rawson used for his process of preparing the indigo solutions for testing. As a matter of fact, the errors in sulphonating would not affect his method any more than any other method in which indigo was dissolved by sulphuric acid. He had never tried the action of lead acetate. The principle of his method was to

obtain a neutral solution, and this, of course, would not be the case if he were to use acetate of lead, as after precipitation the solution would contain free acetic acid. As regards the sampling, it was the usual method to take an average sample of the deck samples. Where the check came in was that the deck samples were not always to be relied upon, and where important contrasts were in question, it was always advisable to obtain a special sample and compare that sample with the ordinary deck sample test. In answer to Dr. Knecht and Dr. Feilmann, there was no doubt whatever that no indigotin was carried down with the precipitate. In answer to further questions of Dr. Knecht, he must reiterate that the volume of solution and the strength of the permanganate were exactly those proposed by Rawson. With regard to the factor which he used for calculating the strength of the indigo from the permanganate solution, he could only refer to his previous publications in which he had always advocated that in matters connected with volumetric analyses the titre of the solutions should not be determined in a roundabout way, but with the use of the identical substances which one required to test. He applied the same principle in this case, and in the first instances, therefore, prepared a solution of pure indigotin carefully prepared and known to be pure in sulphuric acid. He took care that the sulphonation took place at the same temperature at which he was going to sulphonate in dealing with commercial samples and that practically the same quantity of indigotin was taken for the standard as would be used in his future tests. He diluted the pure solution of indigotin to the same volume as he would use in every subsequent analysis, and in that way obviated as much as possible those mistakes which might be inherent to these operations. Of course once the relation between permanganate and pure indigotin was obtained in this way, the strength of the permanganate could be ascertained in its relation to a pure ferrous salt and the permanganate solution, and in future could be standardised by means of such a ferrous salt. With regard to the absorption of indigotin solutions by filter paper he did not think that it would affect any method very much. At the same time, there was no need in his method of filtering as the precipitate settled out very rapidly, and left a clear solution which could be decanted after half an hour's settling or even less.

New York Section.

DR. RUSSELL W. MOORE IN THE CHAIR.

CARBON TETRACHLORIDE AND ITS USE AS A SOLVENT FOR DIFFERENTIATING BITUMENS

BY CLIFFORD RICHARDSON AND C. N. FORREST.

Carbon tetrachloride has attracted of late very considerable attention owing to the fact that it has been made available at a lower price and in a purer form than heretofore, and it has been suggested as a substitute for carbon bisulphide as a solvent. Tetrachloride, as is well known, is made by exposing a mixture of the vapour of the bisulphide and chlorine to a red heat, forming thereby carbon tetrachloride and sulphur chloride. If the heat is too low, carbon bisulphide remains in the tetrachloride, and, if too high, carbon trichloride (C_2Cl_6) is formed. As a result of this, or because of inefficient purification, much of the tetrachloride that has been on the market heretofore has contained from 1 to 2 per cent. of bisulphide, thus impairing its suitability for certain purposes.

The physical properties of the two solvents may be compared with interest:—

	CCl_4 .	CS_2 .
Odour	aromatic	rank
Inflammability	non-inflammable non-explosive	149° C. vs inflammable explosive
Specific gravity $15-15^\circ\text{C}$.	1.604	1.270
Vapour tension	low	high
Specific heat	high	low
Index of refraction ..	1.464	1.628
Boiling point	76.6° C.	46° C.
Toxic effect	none	poisonous

The early supplies of carbon tetrachloride which came into the writers' hands had a sp. gr. of 1.593 a pale straw colour. On distillation, this material began to boil below 43°C ., showing the presence of some substance of even lower boiling point than carbon bisulphide. On continuing the distillation through an 18-in. Young dephlegmator the following results were obtained on a common tetrachloride of sp. gr. 1.593:—

Below 43°C	0.13 per cent.
43 to 47	0.31
47 to 50	0.10
50 to 60	0.31
60 to 70 ..	43 to 60 (total)	0.85	0.22
70 to 75	0.05
75 to 76.5	0.61
Total	1.73 per cent.

It appears that 1.73 per cent. of the tetrachloride distilled below the boiling point of the pure tetrachloride. On further fractionation 1.5 per cent. of pure carbon bisulphide was obtained from the lower fractions, the residue boiling above 77°C . left, on spontaneous evaporation, a substance which sublimed very readily into quite pure crystals of carbon trichloride, C_2Cl_6 .

More recently a tetrachloride has been put upon the market by the Acker Process Co. of Niagara Falls, N. Y., which has been found to be much purer than the ordinary commercial supply. On distillation under conditions similar to those followed in the examination of the first sample, the most volatile constituent was found to boil over between 70 and 75°C ., and amounted to but 0.1 per cent. It contains a small amount of bisulphide, the boiling point then ran up rapidly to that of pure tetrachloride, the entire distillate in the first fraction below that point amounting to but 2.7 per cent. The material as supplied to the trade by the Acker Co. is practically pure tetrachloride, having a specific gravity shown of 1.604 at 15°C . The solvent leaves no residue on evaporation, although it contains a small amount of trichloride, and is consequently an extremely pure material at least from a commercial point of view.

Considered merely as a standard for extraction on a commercial scale, it is the equal in its solvent power to almost all other solvents, exceeding them to some extent with certain substances. It is miscible with all other solvents of the same class, resembling in this respect carbon bisulphide, and, like the latter, it dissolves a large trace of water.

The greater advantage in the use of tetrachloride as a solvent lies in the fact that while bisulphide is inflammable at 149°C ., in consequence of which it takes fire when vapour comes in contact with a heated steam pipe, explosive when mixed with three volumes of air, it is only quite unflammable, but imparts this property to other inflammable substances, such as benzol, turpentine and naphtha, when mixed therewith. Sixty parts by volume of tetrachloride to 40 of naphtha, 40 volumes of benzol, and equal parts with turpentine prevent ignition of these otherwise inflammable substances. The vapour of tetrachloride is not unpleasant, nor does it appear to have any toxic effect, both of which properties make this material preferable to bisulphide in this respect. Tetrachloride has a much higher specific gravity, 1.604, and a higher boiling point and specific heat than carbon bisulphide, but a lower vapour tension and index of refraction. Owing to its

specific gravity its volume weight is much greater, and a larger amount of it must be employed to obtain the volume of solvent as can be seen from the following table:—

Volume of 1 kilo. in litres.	
62° naphtha	1.366
Benzol	1.131
CS ₂	0.788
CCl ₄	0.6231
Water	1.000

It appears that a pound of bisulphide will go as far as 1.5 of tetrachloride, while a pound of naphtha has the volume as nearly 2.25 lbs.

Experiments have also shown that its solvent action, bitumens at least, is not as prompt as that of carbon bisulphide, probably the lower rate of diffusion being due to greater density.

The value of carbon tetrachloride as a solvent in the extraction of bitumens lies in the fact that it exercises selective action on the hydrocarbons and their derivatives composing many of the native bitumens, residual tars and asphalt, while the true asphalt is dissolved only to the same extent as by carbon bisulphide. The same may be said in regard to gilsonite, but native bitumens as grahamite are not soluble in tetrachloride at air temperatures to the same extent as in carbon bisulphide, as much as 75-80 per cent. of an insoluble nature having been found in a mine from Colorado, although the type of grahamite of West Virginia contained but 1.3 per cent. in this form.

The value of the solvent for differentiating the bitumens to which any native bitumen has been weathered and condensed is, therefore, apparent.

The addition of value in another way in revealing any bitumens which may be brought about in a bitumen which is quite soluble in tetrachloride in its native state, when injured by treatment at excessively high temperatures in industrial processes. For example, residual tars carefully prepared from California and Texas bitumens having an asphaltic base, are entirely soluble in tetrachloride at air temperatures, but, as they are used industrially, they contain from 1 to 7 per cent. of insoluble matter in a form not soluble in tetrachloride, very strong evidence that the original bitumen has suffered change in character at the high temperature to which they have been submitted, this often reaching 700° to 900° F. In the same way, in the careless refining of asphalt for industrial purposes, the bitumen may become more or less insoluble and insoluble. If this has taken place it can be detected by determining if anything is present in the tetrachloride which is soluble in carbon bisulphide. As an example, an asphalt recently introduced on the market, the facilities for refining which were inadequate, showed 17 per cent. of bitumen insoluble in tetrachloride, but, with improvement in the process of refining, this form of bitumen gradually disappeared. Carbon tetrachloride is a solvent of value in determining the character of bitumens seems, therefore, to be well established. It must for this purpose, however, be employed at a temperature not exceeding 25° C., and should be free from carbon bisulphide, and, as used in this way, the author can cordially recommend it to those interested in the examination of native bitumens.

Scottish Section.

Meeting held at Glasgow on March 7th.

MR. JAS. HOPE IN THE CHAIR.

GOLD EXTRACTION BY CYANIDE: A RETROSPECT.

BY JOHN S. MACARTHUR.

It is now about 15 years since I read the first paper on this process to this section of the Society of Chemical

Industry. If this were a chemical society only, I would not feel free to offer this paper, but the Society being industrial as well as chemical, my hesitation is less, as it appeals specially to the undeveloped aspect of chemical invention and progress.

At the date when I had the honour of appearing before you previously, the process had not been long before the public, and it was not so well known or understood then as infinitely extended practice has caused it to be known and understood since.

In order to make everything clear, I shall, in a few sentences, broadly describe the general operation of gold extraction from ordinary gold ores apart from alluvial operations or smelting methods.

The ore, which may be taken as composed principally of silica with a small proportion of metallic sulphides, as brought from the mine is broken and finally crushed into sand by powerful machinery and forthwith washed over mercury-coated copper plates which collect, entangle and amalgamate with the small particles of free gold, while the partially exhausted sand passes on. But the sand is not nearly exhausted, as this operation often recovers less than half the total gold contents, and seldom more than two-thirds. The gold thus escaping may be closely associated with the metallic sulphides very finely divided, or, for some other reason, not capable of true molecular contact with the mercury. A proportion of the escaping gold could in many cases be recovered by collecting the heavy metalliferous portion of the escaping sand, now called tailings, and treating by chlorination or smelting. Allowing for this economy, the total recovery must be regarded as low, and the total loss high. Indeed, there were many cases where the amount of gold recoverable by the recognised processes was so low that the ores, though richer than many, were not worked, simply because the mercury-coated (amalgamated) copper plate would not do its work. Ores were roughly classified as "free-milling" when they yielded their gold freely to the amalgamation process, and as "refractory" when they did not respond to it.

The cyanide process was designed to treat gold ores generally, and is well suited to do so, but for various good reasons has found its principal sphere of usefulness in treating tailings or residues from amalgamation.

The cyanide process consists in treating the crushed ore or tailings, as the case may be, with a weak solution of an alkali cyanide, containing generally under 0.5 per cent. of cyanide, which substantially dissolves the gold and substantially leaves the other constituents of the ore undissolved.

The gold solution being drained off, or displaced by water, is caused to flow through a mass of zinc shavings or threads, which precipitate the gold as a fine powder, while the solution passes on, containing a large proportion of active cyanide available for the next operation.

The circumstances which led up to this invention were these:—

About midsummer of 1886 the "Cassel" process of gold extraction, by the solvent action of electrolytically generated chlorine on the gold ore, was attracting great public attention. It was then reported that this process had solved the problem of gold extraction from all sorts of refractory ores, and that millions of tons of ore and tailings scattered over the world could now be profitably treated. It had already been discovered and admitted that the nascent chlorine acted so energetically on the pyritic constituents of the ores, that the base metal compounds were dissolved and the gold neglected. This difficulty was understood to be overcome by the addition of lime, so that the gold was dissolved by nascent chlorine in an alkaline solution which was a precipitant rather than a solvent of base metal compounds, principally those of iron.

The process was at the stage of large scale testing, with works in London under the charge of the inventor Mr. H. R. Cassel, when suddenly circumstances compelled him to abandon his post, and he left the country, at the same time leaving the affairs of The Cassel Gold Extracting Company in great confusion.

Having had occasion to look critically into this process, and in course of writing an article on the subject for a

weekly journal, I came to the conclusion that the same result, i.e., the dissolving of gold freely, with greatly restricted action on the base metals, could be accomplished without the electric current and without mercury, by the use of chlorine or bromine in presence of a salt which—

- (a) Would not absorb chlorine or bromine.
- (b) Would not precipitate gold.
- (c) Would precipitate base metal compounds.

Perhaps there is no salt that absolutely fulfils these conditions, but bleaching powder and borax and boroborate of soda approximate to it, and, generally speaking, the salts that are (or then were) used in toning photographs were of this type. I proved that chlorine and bromine, along with such salts, did dissolve gold, but the action on pyritic and base metal compounds was less easy of proof.

At any rate, this method was tried on a sample of gold ore with such success that a Research Syndicate, consisting of Dr. R. W. Forrest, Dr. W. Forrest, Mr. Geo. Morton and myself, was formed to investigate and, if possible, develop the process into a commercial success; but we failed in this, for again the halogen, notwithstanding the moderating effect of the added salts, worked too vigorously and spent its expensive energy on the base metals, and to our disgust neglected the more valuable gold.

At this juncture, the Directors of The Cassel Gold Extracting Company requested me to undertake the task of resuscitating and perfecting the Cassel Process, and the arrangement was completed on the footing that the Cassel Gold Extracting Company should have the first right to acquire any discovery or invention which might result from the efforts of the MacArthur-Forrest Research Syndicate. Thus the work on the Cassel process and investigation on independent lines were carried on simultaneously.

We had soon found that our sub-alkaline halogen solution was not to be effective, but, encouraged by the confidence of our far-seeing financial partner, we continued our researches to find a gold solvent that would not be a base metal solvent. Naturally this excluded all reagents of the *aqua regia* and acid type, and restricted us to solutions alkaline to test paper or at least neutral. We could not hope to restrain an acid solution from a vigorous attack on the base metals which, owing to their stronger affinity and greater mass, competed unfairly with the gold. In fact, the industry of molecular attack on gold had to be protected to prevent the indiscriminate dumping of base metals into the solution.

Having regard to the many who, like ourselves, were then searching for a process of extraction, and to the fact that results were frequently reported from the difference between original assay value of the ore and final assay value of the residue—a method frequently open to grave objection—we decided not to consider as extracted any gold unless we actually handled and weighed it. As the most generally useful and applicable precipitant of gold we used sulphuretted hydrogen.

Among the various solvents on our programme for trial, we had included potassium cyanide, and in November, 1886, we tried the effect of it on the tailings of one of the Indian gold mines, and, as usual, treated the solution with sulphuretted hydrogen for recovery of the gold, and, getting none, we passed on to our next solvent, meanwhile observing our rule of labelling the residue and laying it aside. We had neglected to notice that sulphuretted hydrogen did not precipitate gold from its solution in cyanide, and thus our experiment was, for the time, literally relegated to the shelf.

About eleven months after, I had occasion to devise a rapid method of gauging approximately the gold contents in weak solutions of gold chloride, and used for the purpose tin chloride to produce the well-known purple of Cassius. One solution that I had to test contained mercury, and, using potassium cyanide to separate the mercury and the gold, I was apprised of the fact that sulphuretted hydrogen did not precipitate gold from its cyanide solution. Instantly my mind reverted to the experiment carried out nearly a year before, and I saw that it might have been successful without the success being recognised. Immediately a sample of rich concentrates from a Californian mine was treated, and on this occasion we examined the residue rather than the solution, and found a high per-

centage of extraction. A sample of poor concentrate from India was now treated, and again a high extraction was obtained.

The results were startling. We unearthed the residue from the old experiments (all our work was done in duplicate) and to our intense satisfaction we found they too had transferred their gold to the cyanide solution. There was now no doubt about the importance of discovery, and at once a provisional specification was drafted and lodged. The guidance on this subject obtained from chemical and technical text books was scanty, meagre and sometimes misleading. The standard books of reference on chemical matters must copy largely from a few original sources, and, if an inaccuracy or error occurs at the fountain head, it is sure to be perpetuated. We could get no information whatever on the action of cyanide solutions on gold ore, and no direct or reliable information as to the action of cyanide on the ores of base metals. We did get, however, some information regarding the action of cyanide solutions on the metals themselves. For instance, Elsner states (*J. Prakt. Chem.* 37 [1846], 441) that iron is soluble in cyanide solution, but mercury is not acted on—both statements palpably erroneous. Other investigators stated that mercury dissolved in cyanide solution, but the fact that commercially pure iron was not appreciably acted on was noted, I believe, in the course of my own work. Possibly the iron used by Elsner contained some silicon—hydrogen would be evolved, but no iron would be dissolved.

Let me give another instance of the imperfect and contradictory information obtainable from standard works. In a most valuable work, published quite recently, there occurs the following statement:—

“Some of the insoluble cyanides are readily decomposed by dilute acids, e.g., cyanide of lead and cyanide of zinc.”

and a dozen pages further on in the same book:—

“No cyanide of lead has been isolated.”

I now do not hesitate to accept the latter of these contradictory statements as correct.

There was a similar confusion as to the action of cyanide solution on gold. Elsner stated that oxygen was necessary for the reaction. Percy (referring to silver) says that either hydrogen is evolved or oxygen derived not from the air, but from any cyanates that might be present (Percy's Metallurgy, Part I., pp. 114–115). G. L. Clark also thinks the cyanates may supply oxygen. Faraday indicates clearly that air contact and the formation of air voltaic circles are necessary for the reaction. He does not hint at any oxidising action being necessary (*Phil. Trans.*, Vol. 147, p. 147). As Faraday may fairly be taken to represent the high-water mark of knowledge in this subject in his generation, I think it well to quote his words. Referring to the dissolving of gold leaf in cyanide solution, he says:—

“Air voltaic circles are formed in these cases, and the gold is dissolved almost exclusively under their influence. When one piece of gold leaf was placed on the surface of a solution of cyanide of potassium, and the other moistened on both sides, was placed under the surface, both dissolved; but twelve minutes sufficed for the solution of the first, whilst above twelve hours were required for the submerged piece. In weaker solutions and with silver also, the same results were obtained: from sixty to a hundredfold as much time being required for the disappearance of the submerged metal as for that which, floating, was in contact both with the air and the solvent. An action of this kind has probably much to do with the formation of the films described hereafter.”

These references and all others available refer to the action of cyanide on metallic gold with which we have little concern, and did not touch on its behaviour towards ores or the minerals usually found in ores.

Amid all this confusion of authority, we had to work out a metallurgical process rather than attempt to solve delicate chemical questions concerning reactions of pure materials.

On the general assumption that the addition of oxygen or at least air contact was necessary for the chemical action, we constructed our first apparatus with a won-

ement of ploughshares which turned the ore with cyanide solution, over and over, always giving fresh surfaces to the air. This apparatus gave good results that we tried the simplification of ploughing, which also did well, and we came down to a rolling barrel, which did equally well. After this we went down to a plain percolation of the cyanide solution through the ore, which gave such satisfactory results we concluded that, even if air contact or oxygen were necessary, it was not necessary to devise any special apparatus to introduce air to the mixed ore and cyanide solution. Thus all special mechanism was eliminated and the process became less of a complex process and more of a simple operation.

While this practical work was being carried on, the chemical aspect was not neglected. Experiments were made on ores treated with cyanide solutions which were made from water boiled to expel all dissolved air. The extractions were the same as under normal conditions. At this time I also suspended a sheet of gold fine thread in a cyanide solution, about an inch from the surface of cyanide solution, and found that it dissolved surely and steadily. It was clear that there was no need for air contact, and as no one had ever suggested that air or oxygen was dissolved and held unchanged in the solution, all appearances went to show that the chemical action was independent of oxygen.

At that period I expressed my opinion on the subject of the section, thus:—

Elsner has stated that metallic gold dissolves in a solution of potassium only in presence of oxygen. Not having seen the original account of Elsner's researches, I am not in a position to criticise his experiments, but I never could find that the presence of oxygen was necessary either to dissolve gold by itself or from ores by cyanide. If a piece of gold be immersed in cyanide solution, so that air to act on it would have to penetrate several inches or three inches of the solution, the gold will dissolve in its usual slow and steady fashion. The evidence shows that either oxygen must be absorbed or hydrogen evolved. I have seen no evidence of the former, and can adduce no proof of the latter; but I think the latter the more probable, because I cannot conceive oxygen penetrating even a film of cyanide solution without at once oxidising the cyanide to cyanate.....

However, we do not concern ourselves much with reactions of pure gold, but, as a matter of fact, we do not find that oxygen plays any part in the cyanide action of gold from ores. We have treated an ore with cyanide with free access of air, and then a parallel experiment was done with boiled water, the bottle filled with the stopper with solution and ore, and the stopper sealed. The extraction was the same in both cases. Over and over again this guarded statement of a reaction, admittedly imperfectly understood, has been converted into an absolute assertion that oxygen was unnecessary.

The question was solved as regards metallic gold *per se* by MacLaurin of Auckland, New Zealand, who discovered the fundamental fact that oxygen remained uncombined in the solution along with cyanide, and did not, as usually stated and assumed, oxidise the cyanide to cyanate (Proc. Chem. Soc., 1893 [122] 81). He confirmed the statement usually attributed to Elsner:—

The cyanide process had been in general and increasing use several years before MacLaurin instituted his research. The fact of its economical working proving the utility of the solutions in spite of protracted air exposure was naturally carried with it the suggestion that, requiring the necessity for oxygen in the chemical reaction, the solution must be soluble, unchanged, in the cyanide solution. It was, however, left to MacLaurin to prove definitely that it had been mistakenly called Elsner's equation, which, in fact, now ought to be called MacLaurin's equation. As a matter of fact Elsner does not give this equation. Numerous experimenters, myself included, had not reckoned on oxygen being held free and in solution in cyanide solution, but had gone on the text book assumption that

cyanide solutions readily absorbed and combined with oxygen to form cyanates, another mistake. In practice, cyanide solutions of the fixed alkalis are now found to be stable in air for all ordinary purposes.

There is a strong general tendency to assume that the reaction between cyanide and metallic gold is reproduced exactly in the case of the gold contained in ores, and this general assumption has often obscured metallurgical investigation. No allowance has been made for the number and variety of mineral substances, possibly unacted on themselves, but still capable of modifying the reaction between gold and cyanide. Highly suggestive work directed towards the elucidation of this complicated problem has been carried out by Gore, who found that metallic gold was dissolved more quickly when in contact with some minerals than with others, and that such inert substances as ground glass and sand had a distinctly accelerating influence. He found that a gold disc lying on clean white sand dissolved nearly five times as quickly as when merely immersed in cyanide solution. What is the nature of the action in this case, I do not pretend to say. No one has yet suggested that sand has any chemical action under the circumstances. Possibly they occlude oxygen—I cannot say.

Another investigator found that the merest trace of ferric oxide induced the action. Again I do not pretend to explain; but, if this is so, the comparatively easy and rapid dissolving of gold from ores is accounted for, as practically all auriferous ores contain more or less ferric oxide.

Acting on the assumption that the chemical action is the same in the case of gold ores as in the case of gold already extracted, refined and prepared, many propositions have been made to apply air or oxygen by mechanical means to the ore and cyanide mixture—compressed air in all forms, mazes of perforated pipes and stirring apparatus have been tried in all countries; but, as far as I know, not one has been worth the trouble involved or has justified its existence, and all have therefore dropped out.

Many chemical means of oxidation have also been suggested—peroxides of barium and calcium, bichromates and even nitroglycerine; but they are little heard of now.

Other methods of oxidation (without oxygen) have been proposed, by which cyanogen has been generated direct to combine with the gold. The principal of these are the addition of ferricyanide (of any alkali metal) to the usual cyanide solution, used in the laboratory by myself, but afterwards independently worked out and patented by Moldenhauer in 1892; and bromide of cyanogen suggested by Dr. E. J. Mills to myself in 1888; but independently worked out by Sulman and Teed in 1894-95. This last method—the Sulman-Teed—is the only modification of the original Cyanide Process as invented and described by the Forrests and myself that has taken root. It has been found of great utility in working the tellurides of Western Australia, but not much heard of elsewhere.

So far, we have dealt with the problem of getting the gold into solution, which is by far the most difficult part of the question. The precipitation from solution is comparatively easy. We knew well that zinc precipitated gold from its cyanide solution; but it remained to make this reaction industrially applicable. We used various forms of finely divided zinc with more or less advantage; but a picture of some fine zinc shavings, bought with other things in a shilling box of chemicals in my boyish days, haunted my mind, and repeatedly I described it to one of the works foremen without effect, until one day, when making a zinc case for packing cyanide, he made a shaving by a sharp tool and came asking me if this was what I wanted. My reply was "Yes," and in half an hour he had prepared the first bundle of zinc shavings for gold precipitation—the pioneer bundle of hundreds of tons of this flimsy but useful material.

We had of course to design an apparatus for using the zinc. Here the difficulties of small scale work hampered us seriously. It seemed such an easy matter to put the zinc in a jar with a hole at the bottom and allow the gold-cyanide solution to run through it; and this simple scheme did very well for a few hours; but gradually the interstices in the zinc mass became choked with extremely

fine precipitated gold, the solution flowed more and more slowly, till finally the zinc mass became geyserous and the solution overflowed. A small tank, really a water-tight box with compartments arranged for the well-known alternate up flow and down-flow, was used; but the down-flow compartments did not work satisfactorily. Finally the form now in use, in which the down-flow is through zinc-less compartments and the up-flow through zinc-fall compartments, was devised in its first form by the metallurgists then in charge of the Mt. Arthur-Forrest installation in New Zealand. It was modified in detail by myself, to economise space and give ease of working, and was used in 1890 in substantially its present form.

Zinc precipitation is one of the weak points in the process. With care, the precipitation is complete to a few grains per ton, but the gold is collected in such fine mud, drying into dust, that loss is inevitable. Various modifications have been suggested in the method of precipitation, to avoid this and other inconveniences. Zinc itself has been used in the form of a fine dust which was mixed with the cyanide-gold solution into almost an emulsion. The gold was quickly precipitated and the gold precipitate with a large excess of zinc allowed to settle, and was then collected. This, however, did not get over the trouble of the gold being in soot-like dust, liable to loss with each breath of wind. This method was worked in conjunction with the cyanogen-bromide modification of the cyanide process by Messrs. Sulman and Teed.

The use of aluminium as a precipitant was proposed by Moldenhauer, and its use advocated on the grounds that the gold was precipitated in reguline form on the aluminium wires used and no cyanide was consumed in the reaction. This method, however, never took root, because the gelatinous precipitate of alumina which formed in the reaction was a greater trouble than the powdery gold.

Electricity was proposed and brought into use as a precipitant by Messrs. Siemens and Halske. The cathodes were made of sheet lead, and the anodes generally of iron. The current was of low voltage and moderate amperic density.

The precipitating tanks were enormous in size as compared with zinc boxes. The gold coated cathodes were fused and expelled at regular intervals. By this means the gold was recovered as gold without the risk of loss of dust.

Electricity is well-known and much used as a precipitating agent for electro-plating and for refining metals, but its use in these industries did not involve the complete precipitation of all the metal in solution; there always remained a store of metal which maintained its conductivity. The solutions used were maintained as true mother liquors.

The case in the precipitation of gold is very different—the proposition involves the precipitation of the gold to the last molecule as nearly as possible. The electric current is obviously not economical in this respect because as the solution becomes weaker and weaker in gold, it becomes, if anything, a worse conductor. The current must increase somewhat in electro-motive force and spend its energy on the gradually weakening solution. In fact, the weaker the solution became in gold, the stronger, the more wasteful, the more costly and the less effective the current became.

In practice there was always a comparatively high amount of gold left in the solution which, though need over and over again on fresh lots of ore, led to loss by leakage and dissipation. In fact, it is a wonder to me and a credit to the technical staff concerned that good results were really obtained. The electric precipitation method is less used now than ever and seems to be dying out.

When solutions are very weak in free cyanide or when they contain copper, they are not easily precipitated by zinc in the ordinary manner (though the difficulty in weak solutions has been greatly exaggerated). But this difficulty has been overcome by using zinc coated over with precipitated lead. This is carried out by adding a small quantity of a lead salt to the gold-cyanide solution as it enters the zinc box. This method was devised by me, and patented in 1894. The application for a patent in the Transvaal was refused on an objection lodged on

behalf of the Chamber of Mines—thus the process dropped out of sight in the Transvaal until 1898, when it was rediscovered by Betty, who worked it most successfully. The introduction of the lead coated zinc had much to do with the desertion of the electro-precipitation process.

The precipitation of gold by charcoal has been used in various places, but, if it survives at all, it is on Victoria. It is difficult to imagine why it was installed, as it has all the disadvantages both of the chemical and electrical methods. The gold-bearing solution passed through a great mass of wood charcoal in which the gold deposits. After a comparatively short time of settling the charcoal ceases to act and the gold is recovered by slowly burning the ashes which, being of the dust-like texture, are blown about by every breath of air. This danger is escaped, the gold dust and ashes are transferred to a crucible and fused into bars in the ordinary way. The chemical action involved in this precipitation is not generally understood—the assumption is that it is due to occluded hydrogen and hydrocarbons. In any case this method combines the inconvenient size of an electrical precipitation plant with the duty form of precipitation, which is too prone to vanish with the wind.

When I first went to Johannesburg, in May, 1890, gold production was less than 40,000 oz. per month, the boom was off, the town was one third empty, there were more rooms than occupants, stores were either empty or filled with derelict goods and everything looked bleak. In the course of a year or so, the potentialities of the cyanide process were dimly realised, the gold output steadily increased, confidence was restored, moribund mines re-opened, fresh capital provided, the once dry "blue ground" in the lower levels where the old ores gave place to more pyritic ores was now covered with valuable asset, deep claims were pegged off, and the new value of mines, shares, town properties, mercantile businesses, and of the country itself, rose enormously. Production increased, the country became more and more attractive, controlling, till at last one of the fiercest and most memorable wars of the age was fought because of the immense successful application of an industrial invention.

What has happened on a huge scale in the Transvaal has occurred in analogous cases in New Zealand, Queensland, Western Australia, United States of America and in fact, in gold producing countries generally. In all these countries heaps of tailings, worse than valueless, became the mother earth of springs of gold. Ore deposits known to exist, but of doubtful nature as to profitable exploitation, became valuable—one in New Zealand offered in Glasgow and in London in the pre-cyanide days at £3000 was refused; fortunately for the owners the market value is now about £500,000.

It is not easy to enumerate the advantages conferred on the gold industry and on the world generally by the cyanide process. It adds directly to the world's store of gold about 20 per cent., and indirectly very much more because of greater profit accruing to the cyanide operation which permits mining and mill amalgamation to be carried on in conjunction with them where they would not have yielded enough profit to stand alone. In fact, in many cases where ordinary milling would not recover the gold to pay for itself and for mining, cyanide steeling recovers another moiety of gold at a cheap rate, and makes a profit for the complete chain of operations. It has made an industry of the two stages of mining and milling which not only is able to exist where, with cyanidation added, the industry obtained a new lease of life. Speaking generally this may be said to be the case in South Africa. If cyanide were to be withdrawn from the Rand, the huge gold industry now so firmly established would dwindle and many individual cases, die. This is true, in degradation, of many gold fields.

The question is often asked—How would the world have fared with its increasing population and relatively decreasing supply of gold if the ratio had not been maintained or restored by the advent of cyanide? I cannot answer this question, and must leave it to the professional metallists and bimetalists to settle between themselves.

One of the most beneficial effects of the cyanide process has been the introduction of exact methods and work where rule of thumb had reigned supreme. The

ago only a very few of the largest gold mines had ores and tailings systematically assayed. Now, a gold mine of the slightest pretensions has its assay and equipment. In the old days the manager, the miner, metallurgist and commercial head in one, knew how much gold he saved, but did not know how much he lost; if he were a "practical man" he rather feared to this latter and stoutly maintained that he recovered the gold. All this is changed; cyanidation compels exact weighing, measuring and computing in its own right, and the cyanide department is generally the exactitude had to begin at the beginning. In a gold mining and reduction establishment is now erected on lines that would do credit to a highly organised factory, or even to a royal mint.

Resulting from the necessity for accuracy imposed on metallurgical establishments, a demand sprung up for assayers and chemists to such an extent that for years there were more good places than thoroughly qualified to fill them—thus the cyanide process has provided durable employment for hundreds of trained scientific thousands of workmen, and tens of thousands of boys, in the midst of the cities of Europe, far from the scene of operations, the cyanide process has stimulated the use of cyanide, formerly manufactured in pounds, now produced in tons, virtually inaugurating a new industry and giving employment to thousands of men. In the early days of the process there were many prejudices against it, some founded reasonably, others not so; the former may be named the risks run in handling a powerful poison. Happily the risk has been proved slight, as very few human lives have been lost by using in the use of cyanide, and, as far as I am aware, a single life has been so lost in the manufacture. Valuable work was accomplished at this time, and during the whole life of the patents, in the laboratory and works of the Cassel Company, but the peculiar position of that company as patentee and licensor prevented it from publishing fully the result of the researches undertaken by its staff. Much of what has been worked out by the original research of others published to the world had already been worked out by the staff of the Cassel Company, but as patentees' hands were tied and their mouths closed as far as the general public were concerned. Thus much of what appeared as original discovery had been known to the staff of the Cassel Company and their associates by reason of original research and the circulation of results among those directly interested.

I have claimed much for the cyanide process, and I am justly, but I do not claim perfection for it, on the contrary I hope to see its scope widened and its field of usefulness increased. The first point on which improvement is suggested is in the price of potassium cyanide. In the early days of the process (1892), we could buy potassium cyanide 98 per cent. strong at 1s. 4d. per pound, now it is only 8d.; but as the consumption does not average over a ton of material treated, the saving of 8d. per ton is of such importance as to materially affect the economy of the process. In fact, if cyanide were as common salt the economy on material presently required would be measured only by pence per ton. I look for improvements in other directions. Ordinary cyanidation the extraction of gold probably does not average more than 80 per cent.—any modification or improvement that would raise this average to 90 per cent. would be much more valuable than a fall in the price of cyanide to the price of common salt. Assuming an average grade of tailings now treated to be 5 dwts. per ton, an additional recovery of 15 per cent. would equal an extra ton, which is about the whole working cost of cyanidation. Thus, in my opinion, the betterment of the cyanide process is a most tempting field for research and improvement.

There is also improvement wanted in widening the scope of operations in which cheap cyanide or a cheap process of cyanide recovery may play an important part. Cyanide containing a small amount of copper absorbs so much that they cannot be commercially worked. This

barrier still exists though efforts, with good promise of success to overcome or remove it, have been made by several skilful workers. I anticipate that some day we shall be able to cyanide cupreous gold ores. If so, the scope of the process will have been substantially enlarged.

The cyanide process has seldom, if ever, been adopted for working purely silver ores, though it necessarily treats many ores containing more silver than gold. Silver ores are even more complex and difficult to treat than gold ores, and, being more plentiful, a silver extraction process is urgently wanted, and doubtless some person, destined to succeed, is working out the problem now.

I have said very little about the patents, nor do I think this is a fitting time or place to trouble you with patent reminiscences, as I have imposed my process reminiscences on your good nature; but I will quote sympathetically from a man who is an univalued authority on science and the record of whose experience is a liberal education—Sir Isaac Newton:—

"If I get free of this present business I will resolutely bid adieu to it eternally, except what I do for my private satisfaction or leave to come out after me; for I see a man must either resolve to put out nothing new or to become a slave to defend it."

Yorkshire Section.

Meeting held at Queen's Hotel, Leeds, on Monday, February 20th, 1905.

PROF. PROCTER IN THE CHAIR.

THE VALUATION OF LUBRICANTS WITH SPECIAL REFERENCE TO CYLINDER OILS.

BY F. W. RICHARDSON AND H. NORMAN HANSON.

The question of the valuation of lubricants is one of the most complex which can be submitted to the consideration of the practical chemist, and we venture to think that hitherto no very clear solution of the problem has been given. The engineer suggests that someone of the various mechanical oil-testers would give better results than the chemical and physical methods employed in the laboratory; but it is not only our experience, but the opinion of others far more competent to judge, that no mechanical oil-tester yet devised meets all the conditions required, indeed, we do not hesitate to say that after one week's trial of a certain modern machine of this description not only we, "mere chemists," but also our engineer coadjutors were reluctantly compelled to admit that not a single set of reliable figures had been obtained. The bearings expanded unequally and the friction tests became valueless. Some engineers maintain that the only true method is that of ascertaining what an oil will do in the very machinery which it is intended to lubricate. We submit that this might prove very wasteful and even dangerous, as a succession of bad lubricants might produce serious wear and tear, and lead to pecuniary loss in various ways. We shall not attempt to do more than suggest certain methods which may prove helpful in certain cases; also, at the same time, pointing out the doubtful character of some processes now extensively used.

When we have to advise an engineering firm as to the comparative value of certain lubricants submitted to us we always make a fairly thorough chemical examination. We have found the lighter class of lubricants, such as those used for spindles, to consist mostly of hydrocarbons. Cylinder oils are frequently found to consist of about one part of lard, or neatsfoot, or olive oil, with about five parts of a heavy hydrocarbon oil. Rarely we have found the saponifiable oil present in such a mixture to consist of rape or even cotton oil. Solid or semi-solid lubricants have given us such substances as lime soap, potash soap,

palm oil, ceresin wax, graphite and semi-solid hydrocarbons.

The examination of these complex mixtures with a view to a report as to their actual value for lubricating purposes is a matter of great difficulty. The chemist is generally asked to give the gravity and viscosity at certain temperatures and flash points (open and close test). We have never found the specific gravity to be of any practical value, although it may be of use in ascertaining the class to which an oil belongs. Possibly where pure hydrocarbon oils are under consideration the gravity may be of indirect value. For lubricants for light machinery the viscosity taken at the highest temperature the bearings are likely to attain is undoubtedly a very valuable and necessary factor, as also is the surface or film tension—what we might term the "wetting power" taken at the same temperature. The flash point is chiefly of service for insurance purposes, and as a rule tells one little or nothing as to the lubricating value of an oil.

Engineers' specifications for cylinder oils require the viscosities at 212° F., and in some cases at 250° F. From our examinations as well as those made by Messrs. H. W. Wells and Scott Taggart ("Cylinder Oil and Cylinder Lubrication," by H. W. Wells and Mr. Scott Taggart, Part I. Henry Wells Oil Co., Manchester) one fact appears very plain:—at from 500°—600° F. all cylinder oils, good, bad and indifferent, have a very similar viscosity, however much they may differ at 212° F. or 250° F. The curve goes down very rapidly as the temperature approaches these higher temperatures, and from the dip of the curve as the oil reaches 250° F. from 212° F., it is not possible to always say what the dip may be over 500° F. As the super-heat of steam is now often very high, it is quite obvious that the viscosity figures at 212° F. and 250° F. can be of very little real value.

The oil analyst often finds himself confronted with the problem of grading a number of samples submitted for his decisive opinion, and it may be found that to all ordinary tests the oils are very much alike; or, perhaps, there may be certain divergences which are difficult of interpretation. It is in such a case as this where the analyst's real difficulty arises.

We tried to get the film-tension before and after oxidation of the oil in shallow layers in a current of hot air; unfortunately no reliable method of determining the film tension of oils with even approximate accuracy seems to have been devised.

Several treatises on physics give methods of an apparently easy character for the purpose in question.

We have had no difficulty in measuring the diameter of a drop of the oil as required by the method of Sents ("Physical Determinations," W. R. Kelsey (Edward Arnold), p. 71), using a microscope with micrometer eye-piece; but the measurements thus obtained do not allow of sufficient nicety to make the figures obtained of any real value.

The method of drops promised to be more reliable, but after much experimenting we decided that the difference between two results with the same oil when heated to 250° F., was such as to show that the process is of very doubtful value.

Proctor Hall's glass-frame process appeared to be capable of giving the results we desired, but the difficulty of establishing an equilibrium was found to be very great, or at least to be so troublesome that we had to discard the method for oils at high temperatures. No doubt for other fluids under ordinary conditions Mr. Hall's glass-frame may prove satisfactory.

Hall's modification ("Lubrication and Lubricants," by L. Archbold and R. M. Deeley, page 46), of Wilhelmey's method (Archbold and Deeley, *ib.*, page 47), with a thin rectangular glass, metal or mica plate in place of the glass frame took up many hours of our time, and proved to be very disappointing as the plate would separate from the oil in a very erratic and mostly in a quite unexpected manner. We regret that as far as our work with these two

processes with oils is concerned we cannot endorse statement that the results are "concordant" "admit of extremely accurate work."

Supplied by Messrs. Metzger's Medical Centrifuge (supplied by Messrs. Gallenkamp) are small, almost capillary blood-tubes about 2 in. long and graduated in 1/100; it occurred to us that if we measured the diameter of the liquid retained by these tubes and noted the height to which an oil would ascend in a given time, using delicate cathetometer we should be able to get an approximate idea of the film tension.

We devised a special copper vessel which enabled us to heat a shallow layer of the oil without flames of kind interfering with the conditions of the experiment. In this layer we immersed our tube, which had previously been cleaned with caustic alkali and acid.

Four cylinder oils were thus tested:—

	At 181° F.		At 250°
	1st Expt.	2nd Expt.	
	mm.	mm.	mm.
A	30.0	30.8	28.5
B	30.25	30.1	29.0
C	31.25	31.6	26.6
D	31.75	31.75	28.5

The weight of column is $\pi R^2 H d$, and the upward pressure is $2\pi R T$.

$$\text{Therefore } \pi R^2 H d = \frac{2\pi R T}{2}$$

The density of the oils may be assumed to be 0.89.

The radius of the inside of the tube was 0.32 mm.

$$\text{In A, 1st expt., we get } T = \frac{0.32 \times 30.0 \times 0.89}{2} = 4.272$$

$$\text{In A, 2nd expt., } T = \frac{0.32 \times 30.8 \times 0.89}{2} = 4.385$$

$$\text{In A, at 250° F., } T = \frac{0.32 \times 28.5 \times 0.89}{2} = 4.058$$

The method is more promising than any we have tried, but the results obtained with it scarcely enable us to grade oils possessed of much similarity.

In Goppelsroeder's test (compare his "Capillaranalyse") the filter-paper strips did not take up the oils with sufficient uniformity to make them other than useful as a means of distinguishing between one class of liquid and another.

Oil Oxidation and Viscosity.—Most oil-testers will pass a mixture, say, of 10 per cent. of a seed oil and 90 per cent. of a good heavy hydrocarbon oil, as a

ery, inasmuch as the "gumming" test as ordinarily applied would indicate but little difference. We should remember that a cylinder oil is exposed in very shallow layers, in fact, to high pressure and therefore to temperature steam, and that a rational method of testing should take this fact into consideration. To this we have constructed two special copper ovens in which shallow layers of oil can be submitted to the action of steady currents of air at 212° F. and 400° F. respectively. By means of a meter, we measure the air, heated by a flame, and the volume passed in four hours should be practically the same in each case. We use water at the boiling temperature in one, and cedar oil at 400° F. in the other oven, to heat both the inner and layers of oil, which are contained in shallow iron dishes, into which 10 c.c. of the oil have been placed, the weights being calculated. The oven is made of stout copper brazed throughout, outer dimensions are 10 in. by 10 in. by 7 in. An oil jacket surrounds a chamber 5 in. by 7 in. by 1 in. high. The tin plate tray measures 4 in. by 6½ in. by ½ in. deep. The inner chamber is surrounded by half-inch diameter copper tube in eight coils; the last coil enters the chamber at the back at one corner and the exit is at the opposite corner diagonally, and is connected with a half inch copper tube joined to the meter, which is connected with a rubber pump. A tube leads from the centre of the chamber to the air, which is fitted with a thermometer and asbestos joint. After introducing the tray containing 10 grms. of the

oil, the entrance to the oven is covered with an asbestos sheet upon which, by means of two projecting screws (only one screw shown in the diagram, a brass plate is firmly secured by means of fly nuts. (In the diagram only two coils of the hot air tubing are shown).*

A broad gas burner allows of the temperature in the inner chamber being easily raised to 400° F., and we find no difficulty in maintaining a steady current of air at this degree.

The viscosities of the oils are determined before and after oxidation by means of the simple apparatus we now describe. A 5 c.c. pipette graduated in 1/10ths, is secured in a Liebig's condenser by means of corks, with a glass side tube connecting the vessel with a supply of water kept rapidly boiling. The viscometer is tested from time to time with water and a standard olive oil. We make three tests to secure an average result and find the viscometers obtained to agree within 1/5th of a second. The results are simply comparative.

We have not attempted to calculate the absolute viscosities, for the simple reason that the readings in 1/5th of a second are all that we require. All vegetable and animal oils increase in viscosity when heated in air or steam.

Linseed oil is not used in the compounding of lubricants but we submitted it to our process because it shows in more striking manner the identity of the action of hot air and steam.

The following are some of the results which we have obtained at a temperature of 400° F. :—

LINSEED OIL.

	Air at 400° F.			Steam at 400° F.	
	Before Expt.	½ hour.	½ hour.	1 hour.	4 hours.
Viscosity after cooling to 60° F.	fluid	semi-fluid	semi-fluid	fluid	semi-fluid
1/5th sec. at 210° F.	57	78	112	77½	154
Refractometer, degrees at 121° F.—					
Oil	66	70½	73	—	—
Fatty acids	55	60	66	67½	82
Boiling point of fatty acids ° C.	19½	22½	23½	24.8	25.0
H (Hüb) value of the oil	175	171	161	153	144

These data establish the fact that superheated steam acting upon a "drying" oil, produces changes of a similar character to those resulting from the action of hot air; the action is much less rapid, as one might naturally expect. The conclusion deducible from this fact is that the change produced by oxidising an oil in a hot air current is a test as to its "gumming" properties in actual use as a lubricant. In super-heated steam as well as in air at the same temperature saponifiable oils increase in viscosity, refraction and melting point of the fatty acids, whilst the iodine number decreases considerably.

Our view these changes in general are due largely to polymerisation and only in a secondary degree to oxidation, hence the increase of viscosity of the refractive index and the melting point of the fatty acids.

We suggest that the progressive decrease of the iodine number and part of the increase of the melting point may be due to the conversion of oleic constituents into dihydrostearic acid or similar oxidation products. What may be the exact chemical changes oils undergo on oxidation we know that physically the change is in the direction of increased viscosity and the action of hard, gummy substances insoluble in ether. No lubricants which have given very similar results in the ordinary tests may not only prove very different in oxidation test, but also in actual use. Hydrocarbon oils frequently contain small amounts of substances which become resinous in character when heated in a steady current of air at 400° F., yet the presence of these is not revealed by any of the ordinary tests. We have used steam at 400° F., but we should remember that the super-heat in cylinders often gives temperatures

over 600° F., and we are safe in assuming that with such steam the oxidation of the filmy layers of the lubricant will be very much greater.

As the transit of the oil in a cylinder is comparatively brief, it might appear at first sight that there would be no time for polymerisation to take place; but we must remember two salient facts :—

(1) The oil is made to produce a rapid succession of film surfaces;

(2) The steam is not only very hot but is under high pressure.

We have been surprised at the great changes which take place even in the best olive oil when film-surfaces of it have been exposed to hot air or steam for only a few seconds.

Olive and cotton oils undergo similar changes to linseed oil but in a lesser degree, the cotton oil naturally suffering the greater change of the two in every particular; indeed the oil soon becomes solid and varnish-like and only partly soluble in ether.

Before we adopted the temperature of 400° F. we made a large number of tests at 210° F., allowing the current of air to pass for six hours. The chief interest in these results lies in the close connection between the viscometric and refractometric changes :—

* Messrs. Reynolds & Branson, Chemists, of Leeds, will supply this special oven.

4 SAMPLES OF OIL.

	A.	B.	C.	D.

Refractometer at 121° F.	39.5	38.5	39.0	35.5

D oil was reported as being unsatisfactory, and we were told that our opinion was in harmony with the results obtained actual use.

If we exclude sperm oil it will be seen that a close ratio exists between the increase of viscosity and the increase of refractive power. We would therefore suggest that a good method of testing the value of a lubricating oil would be to expose it in very shallow layers; much shallower than those we have used, to a stream of air at 210° F., for 12 hours, and then observe the increase of refractive index, which safely could be taken as a measure of the polymerisation.

We have tried to devise a process which would enable us to predict the results of using cylinder oils as far as their tendency to form non-lubricating bodies is concerned. To all the ordinary tests the defective cylinder oil included in the above table seemed excellent; but when we found that shallow layer oxidation at 210° F. for six hours had increased the viscosity by nearly 10 per cent., we inferred that it was unsuitable for the purpose required, and we were gratified to learn that this very oil had given very unsatisfactory results; indeed in

this way and on several occasions, we have been able to grade oils in a manner which has fully met the approval of engineers who had made long tests in cylinder lubrication.

We are aware that a seeming difficulty may exist in regard to pure hydrocarbons which undergo but a slight apparent change on oxidation as compared with vegetable and animal oils; yet even with these very apparent differences are shown, and when we know how very rapidly these changes take place in the cylinder, how viscosity increases and film tension decreases, we can readily understand how it is that even pure hydrocarbon oils differ so much amongst themselves in actual use.

We append some tabulated results from the analysis of several samples of lubricating oil, and suggest that without such data it would be difficult to formulate a very definite opinion as to the value of a lubricant:

Viscosities and Refractions of Oils Before and after Oxidation, in Shallow Layers at 210° F. for Six Hours

DISCUSSION.

Prof. GOODMAN said he had tested cylinder oils by mechanical methods, but found these useless as the results obtained by different operators and at different times were not concordant.

Mr. COBB thought that the complication of the change whose effects it was desired to measure probably accounted for the conflicting results usually obtained. The rise of temperature primarily lowered the internal friction, but the accompanying thermal changes, in the case of these oils, increased internal friction, and the total

effect was of a differential character. Mr. RICHARDSON seemed to attach little importance to oxidation and much to polymerisation, but one of his principal examples was linseed oil. Was it not definitely proved that oxidation took place in this case, and was it not the main cause of its change in physical nature? It would be interesting no doubt to the members to know exactly what changes Mr. Richardson regarded as occurring in linseed oil subjected to hot air and to heated steam, each process resulting in a lowered refractive value. The two agents were so different in their nature that it was desirable to proceed with caution.

ing that the effect of super-heated steam could be had at once from that of hot air.

WARD understood that Mr. Richardson proposed to use oils on the basis of viscosity caused by high temperature, but discarded viscosities at ordinary temperature. He could not see how viscosity was to be the determining element in one case and not in the other.

YOUNG could not agree in condemning viscosities and thought a curve constructed from observations at various temperatures very useful. Mr. Richardson suggested method would show a pure mineral oil to be superior to the same oil mixed with 10 per cent. of oil, whereas in practice the latter mixture was to be superior. He agreed that olive and other vegetable oils, which Mr. Richardson would condemn as oxidisable, but they should not be condemned as lubricants on this account. He suggested that lubricants were not long enough in cylinders to undergo reactions Mr. Richardson described. Physical tests of opinion were very useful in determining the source of pure mineral oils. Did Mr. Richardson know of hydrocarbon oils mixed with fatty oils in the tests? He thought the explanation of the age obtained by using mixtures of hydrocarbon oils was that the small amount of fatty oil in the mixture to break up into minute particles mixed more readily with steam. He agreed with Goodman in condemning mechanical testing as being unreliable.

MACKEY did not think Mr. Richardson meant to do in the viscosity test, which greatly helped to vitiate mineral oils. Combining viscosity with oxidation he took it Mr. Richardson was trying to show the effect in gumming. He agreed with Mr. Young that tests were not sufficiently long in cylinders to undergo change. The increase of acidity in cylinder oils was a valuable point which had been left unmentioned. He found in practice that a good mixture of fatty with carbon oils, which did not increase in acidity during use through the cylinder, gave best results.

MARSDEN would have preferred comparative tests of Redwood's viscosimeter and Mr. Richardson's; the latter he thought liable to give varying results owing amongst other things to narrowness of tube consequent capillary attraction and friction. The viscosity test was of great value, as the more perfect produced in the cylinder the better the lubricant. The best mixture was perhaps one in which the ages of fatty oil and hydrocarbon were so arranged as to be carried through the cylinder, having done its work, would be carried to the exhaust without deposition of any decomposition products. As the hydrocarbon constituent was important, the effect of oxidation on it must be considered.

PROCTER thought that polymerisation, as well as oxidation, took place in oils during heating. In the case of boiled without blowing, although oxidation was present, there was much increase of viscosity. He drew attention to oils used for gas and motor engines, &c., where temperatures were very high and the oil in many cases remained for a considerable time in the cylinder and in case.

EMER said Mr. Richardson's paper raised the question of what really took place inside a cylinder. The experiments must be different from inside conditions. Greasiness and not viscosity must express the condition of an oil.

SLATTERY thought there was no comparison between superheated steam in their action upon oils. He asked how many of the oils tested were pure mineral oil if hard oil or tallow was mixed with them.

HOLGATE said, in comparing oils such as olive and mineral account must be taken of the fruits, good or bad, and the district from which obtained. Vegetable oils are gumming, whilst hydrocarbon oils were evanescent. Exact results could not be expected in testing oils of different layers of oil in the same case were not of the same composition.

DILLON said that linseed, cotton and other vegetable oils, heated to 400° F., produced varnishes. The seller would offer lubricants containing them. He

thought that increase in viscosity at high temperatures was due to decrease in volume and development of lower fatty acids. As small samples often had to be tested ordinary viscosimeters could not always be used.

MR. RICHARDSON, in reply, said that experiments which he had made with certain oil-testing machines agreed with Prof. Goodman's experiences. Free oleic acid in oils did not oxidise or produce gumming to any great extent, but the neutral glycerides themselves. He maintained that lubricants were materially affected in cylinders owing to high pressure, the rapid production of fine films of oil, &c., and also that changes under the influence of steam and hot air were identical, as had been shown. The fact that some oils, which satisfied the usual physical and chemical tests, did not give good practical results or confirm behaviour when submitted to the action of hot air supported this. The film tension indicated the wetting power. Vegetable and animal oils helped greasiness and emulsification. For this reason 10 to 15 per cent. of hard or neatfoot oil was a very valuable addition. The viscosity test was used to show the gumming which would be produced if the oxidation was carried far enough, and not as a factor of any special value in itself. A rapid increase in viscosity with hot air indicated a bad lubricant. The great bulk of changes, he thought, were due to polymerisation and densification rather than oxidation. Polymerisation would also account for the reduction of the iodine number. The authors had not found any appreciable increase of acidity when glycerides were oxidised. Many pure hydrocarbon oils which he had tested varied considerably in viscosity after being submitted to the oxidation process which he and his colleague had described.

Obituary.

ALBERT B. PRESCOTT, M.D.

DEAN OF THE SCHOOL OF PHARMACY OF THE UNIVERSITY OF MICHIGAN. MEMBER OF THE SOCIETY OF CHEMICAL INDUSTRY, &c.

Albert Benjamin Prescott was born December 12, 1832, in Hastings, New York. In 1861 he entered the University of Michigan, receiving the degree of Doctor of Medicine three years later. In July, 1864, having previously passed the regular army examination for the medical service of the United States Volunteers, he was commissioned as assistant surgeon and assigned to duty in one of the hospitals in Louisville, Kentucky.

His medical career, however, was of short duration. As a medical student he had specialised in chemistry and at the close of the war he resumed his chemical studies as a teacher and investigator, which became his life work. In the autumn of 1865 he was appointed Assistant Professor of Chemistry and Lecturer on Organic Chemistry at the University of Michigan. When the School of Pharmacy was organised in 1868, its administration was placed in his hands; in 1870 he was appointed Professor of Organic and Applied Chemistry and Pharmacy, and in 1884 he was made Director of the Chemical Laboratory. Michigan was one of the pioneers to give laboratory instruction in chemistry, and Professor Prescott was the pioneer in demanding laboratory work of his pharmacy students. He not only succeeded in making elementary laboratory instruction compulsory, but he also led his students to advanced work, to which the "Contributions from the School of Pharmacy of the University of Michigan" in 1875 and 1876, and also the "Laboratory Notes" of 1877, &c., bear ample evidence.

In 1879, Prescott published his "First Book in Qualitative Chemistry," and another work, his "Outlines of Proximate Organic Analysis" next developed into the well-known and complete work on "Organic Analysis," published in 1887. One of his latest contributions is a chapter entitled "The Alkaloïds in Toxicology."

ecology" for the American text-book of toxicology edited by Dr. Walter H. Haines of Chicago, and as Chairman of the Chemical Section of the American Association for the Advancement of Science, at the New York meeting in 1887, he discoursed on "The Chemistry of Nitrogen as disclosed in the Constitution of the Alkaloids."

He devoted much time and attention also to chemical industry and analysis, toxicology, matters of sanitation and hygiene, and the fact that the School of Pharmacy

of the University of Michigan stands pre-eminent today is known to all who have followed the progress of pharmaceutical education in the United States.

Dr. Prescott was elected President of the American Pharmaceutical Association in 1899. The last convention on which he was associated with the Society of Chemical Industry was on the occasion of the memorable meeting at Detroit last September.

He died at his home in Ann Arbor, Mich., February 24, aged 74 years.

French.—1 fr. 25 c. each, to Belin et Cie., 56, Rue des Francs-Bourgeois, Paris (3^e).

I.—PLANT, APPARATUS & MACHINERY.

Pyrometry; Optical. — C. W. Waidner and G. K. Burgess. U.S. Bureau of Standards, Bull. No. 2, 1905, 189–254.

THE subject is discussed under the following headings:—(1) General discussion of optical pyrometry. (2) Laws of radiation: (a) Stefan-Boltzmann's law; (b) laws of energy distribution; (c) Wien's laws; (d) Planck's law. (3) Methods of optical pyrometry: (a) colour estimation; (b) photometric methods; (c) ratio of intensities of two wave-lengths; (d) upper limit of the spectrum; (e) maximum energy in spectrum; (f) total radiation; (g) interference method. (4) Description of instruments and investigation of their calibration, range, sources of error, and precision. (a) Le Chatelier optical pyrometer (this J., 1893, 290); (b) Fery absorption pyrometer; (c) Mesuré and Nonel's pyrometric telescope (this J., 1889, 314, 1891, 139); (d) Wanner pyrometer (compare this J., 1903, 761); (e) Holborn-Kurlbaum pyrometer; (f) Morse pyrometer (this J., 1901, 343); (g) Fery thermo-electric telescope (this J., 1904, 681; 1905, 210). (5) Comparison of various types of optical pyrometers. (6) Special problems in optical pyrometry.

In comparing the various kinds of optical pyrometers, the authors point out that the Mesuré and Nonel pyrometric telescope cannot be considered an instrument of precision, although it is serviceable for the approximate control of temperatures above 800° C., and answers the requirements of many furnace operations sufficiently well. The other instruments examined are all capable of an accuracy of

1 per cent. in absolute temperature-measurement, in ranges for which they are adapted. For relative temperature measurements, the precision attainable is better than 1 per cent., except perhaps in the case of the Fery thermopile pyrometer, and may even be as good as 2° at 10° C. with the Holborn-Kurlbaum instrument. For the lower limit of the Wanner pyrometer and the Fery thermopile electric telescope is about 900° C. With regard to the limit, this is about 1100° C. in the case of the Morse instrument, and 1600° C. with the Fery thermo-electric telescope, but with the other instruments it is higher. For very high temperatures, above 1500° C., in the region where temperatures can only be determined by extrapolation in terms of some law of radiation, the most reliable are obtained with the Wanner pyrometer, and the thermo-electric telescope with fluorite lens can be used directly in terms of Stefan's law. These two instruments are also the best with regard to ease of calibration and control; and the Fery telescope appears to be especially suitable for adaptation as a recording instrument. (See also this J., 1904, 623.)—A. S.

ENGLISH PATENTS.

Pyrometers; Impts. in. — H. T. Barnes and M. T. T. Montreuil, Canada. Eng. Pat. 12,253, 1904.

SEE Fr. Pat. 344,718 of 1904; this J., 1904, 1203.—F. B.

Evaporating and Evaporating Liquids; Vacuum Apparatus for — A. Neumann and G. Stadel, ia. Eng. Pat. 26,255. Dec. 2, 1904.

claim is for the combination of any devices reducing circulation in such a manner that the vacuum pan is divided into three vertical co-axial compartments. Further, in so placing the heating tubes, for instance below the intermediate compartment, that the liquid is forced, when flowing in one direction, to pass in two separate or partial currents through the innermost and outermost compartments respectively; and when flowing in the opposite direction to pass in one united current through the intermediate compartment. In this way a very thorough heating of the liquid undergoing evaporation is obtained.

—W. H. C.

Off Cock for Viscous Liquids. M. F. C. Müller, Hamburg. Eng. Pat. 29,039. Dec. 30, 1904.

plug *k* of the cock is made spherical, and has two ends *b* and *c* at right angles to one another, and is

FIG. 1.

FIG. 2.

provided with a spindle *s* having a square head *t*. (By the use of such a spherical plug, the difficulty usual with cocks for liquids which on cooling set to a semi-rigid stiff mass, is obviated.) The body is in two parts *g* and *h*, held together by bolts and nuts, *d*, *m*, *s*, through the flanges *e* and *f*. The upper part *g* is made very shallow, so that when the cock is closed, part of the plug projects, as a spherical segment, into the vessel to which the cock is attached by the flange *h*. The lower part of the cock-body has an opening of the same bore as the passage *b*, and a flange *p* for connection to the delivery pipe. Figure 1 shows the cock open, and Figure 2, closed, in which case the passage *c* is closed by the opening *o* and any material in the passage *b* is driven away. It is claimed that the stoppage of the passages by material solidifying in the bore of the plug *b*, in the bore of the cock above the plug is thus avoided.

—W. H. C.

Imps. in — A. B. Lennox, Newcastle-on-Tyne. Eng. Pat. 29,573. Dec. 31, 1904.

The aim is for a vessel of inverted truncated cone shape

having either an open or closed top, and a dome-shaped bottom in which an outlet pipe is provided. In the bottom of the vessel is a wire gauze or perforated metal basket containing the filtering medium, and at intervals above it are perforated trays also supporting filtering medium. The basket and trays are carried on brackets projecting from the inside of the vessel, and so arranged that the upper brackets do not hinder the withdrawal of the trays situated below. The material to be filtered, may either be forced through an opening in the closed top of the vessel, or drawn through by suction applied to the delivery pipe at the bottom, in which case the top is open. The vessel is mounted on trunnions and supports so that, when the filtering medium becomes choked, the whole can be tilted over and emptied.

—W. H. C.

UNITED STATES PATENTS.

Liquid-Separator; Centrifugal — A. T. Salenius, Assignor to W. Meinhardt, Stockholm, Sweden. U.S. Pat. 779,445. Jan. 10, 1905.

FIG. 1.

FIG. 2.

FIG. 3.

CLAIM is made for the combination with the "conical plates" 4, which are co-axial with the separating drum, of a series of "plate members" 1, 2, 3, between the plates. These "plate members" may take different forms as shown in the figures. The object of the invention is to facilitate the separation, by affording means for the oppositely flowing currents of liquid, to gather through the openings in the "plate members" on the surfaces along which they flow, and thus to avoid the great friction between the currents of liquid.—W. H. C.

Distilling Apparatus. J. I. Pittman, Valdosta, Ga. U.S. Pat. 783,307, Feb. 21, 1905.

AN inner casing 1, forming the still proper, is arranged within an outer casing 2, so as to leave a steam space between the two. The inner casing extends above the top of the outer casing, and is provided with a hinged cover 3, with supports 4, for the "basket" 5, containing the material to be distilled, and with a delivery pipe 6 for the vapours. The latter is provided with four valves as shown, and is connected to the condensing coils 11, 12, 13. Steam is supplied from the main 14, to the steam space by the valve and pipe 15, and to the inner chamber by the valve and pipe 16, and the "spider-like" perforated distributor 17. A pipe 18, provided with a valve extends from the inner casing, through the steam space, to the outer casing, and is used for drawing off "tarry products."—W. H. C.

Furnace; Regenerative. S. Groh, Assignor to S. A. Groh, Alexandria, Va. U.S. Pat. 783,429, Feb. 28, 1905.

THE air- and gas-conduits each leading through chequer-work are provided with reversing valves. Beneath the conduits is a flue connected with them and with the stack. A "butterfly-valve" and gate-valve are combined, so that the major portion of the products of combustion can be passed through the air-conduit.—W. H. C.

FRENCH PATENT.

Filter-Press Plate. Niles-Bement-Pond Co. Fr. Pat. 347,696, Nov. 5, 1904.

SEE U.S. Pat. 776,024 of 1904; this J., 1905, 20.—T. F. B.

II.—FUEL, GAS, AND LIGHT.

ENGLISH PATENTS.

[Peat] *Fuel.* R. I. R. Roman, Dublin. Eng. Pat. 700, Jan. 11, 1904.

AIR-DRIED peat cut into small sods, is disintegrated by a

machine, and the peat dust then separated by a winnowing device from the residue. The peat dust is then beaten in a revolving drum by exhaust steam or other means till it only contains from 14 to 15 per cent. of moisture. The dried dust is conveyed to a measuring and pressing machine, the dies and mould of which are heated to between 110° and 180° C., and compressed at a pressure of 180 to 2000 atmospheres.—L. F. G.

Peat; Treatment of —, and Apparatus therefor. Kennedy, Cambridge. Eng. Pat. 6308, March 1904.

PULPED or squeezed peat is placed in a chamber through which pass three conduits connected to a steam or gas heater. Two of the conduits are open at the ends in the chamber, and fans placed inside these openings draw the steam given off by the peat into the superheated steam chamber. The superheated steam issues from perforations in the third conduit, and further heats and dries the peat. A non-return valve placed near the bottom of the chamber permits the escape of air as the quantity of steam generated increases. The gases of combustion from the steam heater furnace may also be led through flues placed beneath the floor of the chamber. After drying, powdered peat is compressed into briquettes.—L. F. G.

Peat Fuel; Manufacture of —. J. B. Bessey, London. Eng. Pat. 17,497, Aug. 11, 1904. Under International Convention, April 25, 1904.

FRESHLY-CUT peat or turf which has been freed from its mechanical treatment, is subjected to the action of an alternating current of small strength and voltage, about 20 kilowatts being employed for 1.5 cubic metres of peat, the current strength falling from 200 to 100 amperes in twenty minutes. The current ruptures the cell walls and liberates the resin, oil, pectins and other constituents without causing carbonisation. After expressing the water, the mass is moulded, and hardens of itself, without heating, pressing, or storing.—L. F. G.

Fuel; Smokeless. S. S. Bromhead, London. La Compagnie des Charbons et Briquettes de l'Ouest, Nantes, France. Eng. Pat. 29,564, Dec. 22, 1904.

THE agglomerated fuel, prepared from coal or other materials in any known manner, is distilled in retorts heated to a sufficient temperature to drive off the smoke-forming constituents and increase the firmness and cohesion of the briquettes.—C. S.

Burners; Hydrocarbon —, for use in Furnaces and for other Heating Purposes. F. A. Murphy, Oldham, Lancs. Eng. Pat. 29,564, Dec. 31, 1904.

THE essential feature of the invention consists of a rotating fan with suitably formed blades attached to a central distributing cone, the whole rotating about a shaft inside the oil-supply tube. Heated air under pressure is forced through a tube surrounding the arrangement, and sucks out oil through a hole in a nipple placed at the end of the oil-supply pipe, the mixture of oil and air being atomised by the fan and cone. The surface of the fuel may be smooth or corrugated, or provided with a network of arms.—L. F. G.

Liquid Fuel Burners for Heating Purposes. H. H. Jackson, London. B. F. Jackson, Boston, Mass. U.S. Pat. 21,488, Oct. 6, 1904.

THE burner consists of an outer chamber 1, connected to the blast supply by the collar 2, and having an inner sleeve 3, with perforations 4, 4, and contracted at the bottom. The atomised fuel is conveyed by the pipe 6, terminating in the jet 7, and passing concentrically through the outer casing 1 and the sleeve 3. The pipe 6 is connected to a T-piece 8 with the blast-pipe 9, controlled by the valve 10, and also with the liquid fuel jet 11, controlled by the valve 12. The pressure medium, which may be compressed air or steam, is led to the four-way fitting 13 by the pipe 14; a portion goes by the branch 15 to the reservoir of fuel and forces the latter by the connection 18 through the atomising jet 11, another part passes by the branch 16

ve 10 and the pipe 9, and serves to atomise the
ich it meets at the point 8, a third portion of the
medium passes by the branch 17, into the chamber
entering through the perforations 4, of the sleeve 3,
an annular stream around the jet 7. A Bunsen
may be used around the jet in order to increase
ciency of the burner.—W. H. C.

*1 Coke or other Carbonised Substances; Treatment
al and other Carbonaceous Materials for the Pro-
on of —.* J. Bowing, Tilbury. Eng. Pat.
March 22, 1904.

aim is for the production of coal-gas, water-gas
mixture of both by treating coal or other
aceous materials in a retort with superheated
In the case of coal, the coal gas is first driven
steam at temperatures of from 300° C. to 400° C.,
o coke, but only "soft cinder" is left behind.
e residue, by raising the temperature of the steam,
as is produced, it is claimed, at a temperature
ably below 1000° C. If coke is required instead
fit-cinder," then the temperature of the steam
e about 650° C., and from this coke water-gas is
be obtained at 1000° C. The coal-gas and water-
y be obtained together, if desired, by using steam
gher temperature from the first. It is further
that water-gas can be obtained from sawdust at
, and hydrocarbon distillates at proportionally
temperatures. The apparatus described consists
superheaters, filled with chequer-work, through
the heating gas and the steam to be superheated
anately; a retort in the form of a vertical truncated
rovided with charging and discharging openings;
ted pipes for the admission of the superheated
and an outlet for the gas produced. The gas passes
e retort through a series of condensers immersed
ak of water to the ordinary purification plant.

—W. H. C.

Producers. J. H. Hamilton, Sandiacre, Derby.
Eng. Pat. 7767, April 2, 1904.

roducer described is of the vertical type, to which

air and steam are supplied from the bottom. The grate
is conical in shape and can be rotated step by step by
means of a ratchet and pawl. A cleaning bar is arranged
with its upper end on the grate, while the lower end is
connected with a lever, by which the bar can be moved
lengthways. Means are provided to ensure that this bar
shall be drawn back while the grate is being rotated. To
prevent loss of gas the poke-holes are provided with
a neck, in which is a valve held in its seat by a counter-
poise, "but opened by the insertion of the poking bar
which, however, first closes the orifice of the neck, whereby
the escape of gas in a pressure plant, and entrance of air in
a suction plant, is prevented." This poke-hole can also
be used for the introduction of a tube closed at one end
by a plate of glass, whereby the fire can be examined.

—W. C. H.

*Producer-Gas; Manufacture of —, and Apparatus
used therein.* W. W. Tonkin and S. Puplett, London.
Eng. Pat. 8827, April 16, 1904.

THIS patent relates to improvements on the producer
described in Eng. Pat. 15,498 of 1902 (this J., 1903, 860).
The chief modifications are in the heat exchanger, the
water-tube boiler, and the air saturator. The hot gases
from the producer are made to pass down the middle
division of the heat exchanger, which is provided with
cleaning doors, and the air-blast to pass up the two outer
divisions. In the water-tube boiler the tubes are connected
at the bottom to a branch piece, communicating with a
vessel containing a plunger, by which the height of the
water in the tubes can be regulated; this is done auto-
matically by means of suitable valves. By the improved
air-saturator dry air can be applied at first to the producer,
"and subsequently the amount of aqueous vapour is
automatically regulated by the temperature of the outlet
gas," which heats the water of the scrubber, the overflow
of which saturates the air to the required extent.—W. C. H.

Gas-Producers. E. Schweich, London. Eng. Pat. 11,268,
May 16, 1904.

THE claims cover modifications in the construction of
producers, in which air, or air and steam, are supplied at

the top and bottom of the fuel, and the gas is withdrawn from the middle. One wall may be extended upwards and the vertical line of the upper part of the chamber may be a space free from fuel, and opening into the gas exit. Or a central vertical gas exit may be arranged, and by the upper part of the chamber is divided into two parts. Or the upper part of the producer may be formed with a smaller diameter than the lower, and a gas collecting space formed which communicates with the gas exit. —W. C. H.

Water-Gas: Plants for Making. — L. A. J. J. Nymwegen, Holland. Eng. Pat. 21,217, Oct. 7, 1904. Under Internat. Conv., Oct. 6, 1903.

Two or more pairs of generators are connected with one boiler, so that any one or more pairs can be disconnected from the boiler, when it is desired to throw it out of work; during the air-blast stage, air is drawn through both generators of a pair and through the boiler, and then steam is introduced, when the fuel is at a suitable temperature, into one generator, and the steam and water-gas produced are passed into the second generator of the pair and on to the boiler and gas-holder. Comp. Fr. Pat. 322,721 of 1902; this J., 1903, 358. —W. C. H.

Power-Gas: Process and Apparatus for the Manufacture of. — E. Fleischer, Dresden-Strehlen, Germany. Eng. Pat. 26,770, Dec. 8, 1904. Under Internat. Conv., Dec. 11, 1903.

THIS is a process for the manufacture of power-gas from bituminous fuel, to which air is supplied at the top and the bottom of the producer, while the gas is withdrawn from the middle. The tar-vapours are burned by means of a secondary air-supply, which is introduced at a point beneath the upper air supply and about the vertical axis of the mass of fuel. To accomplish this a ring is arranged in the upper part of the producer, the fuel being supplied to the annular space between the two. The ring is of such a width that when the fuel takes up its natural angle of rest, it forms a crater-shaped depression under the ring. The secondary air supply reaches this crater through slits in the side of the ring. —W. C. H.

Gas Generators. A. von Kerpely, Vienna. Eng. Pat. 28,966, Dec. 30, 1904.

THE generator consists of a vertical, double-walled shell, which is rigidly connected to supporting brackets, and cooled by circulation of water. The lower end of this shell dips into a circular trough, mounted on balls, and caused to rotate by a worm arrangement gearing with the periphery of the trough. This trough carries a rotating grate by which the fuel is kept constantly in motion; air is uniformly distributed through the fuel and the gasification is thus increased. —W. C. H.

[Gas] Retorts; Furnaces with Horizontal. — H. Gielis, Berlin. Eng. Pat. 92, Jan. 2, 1905.

THE furnaces described, are gas fired, and the combustion chamber, which receives the gas from the generator, is arranged transversely to the retorts, and communicates directly with the longitudinal channels formed by the walls of adjacent retorts, by which channels the heating gases are distributed through the furnace. The ends of the retorts, nearer the generator are made wider than the other ends, to obtain a uniform reduction of the charge to correspond with the reduction or heat in the direction away from the generator and combustion chamber. —W. C. H.

Gas-Purifiers. S. Cutler, G. B. Cutler, and S. Cutler, jun., London. Eng. Pat. 5479, March 5, 1904.

COLLECTING or distributing chambers extend along the sides, ends or bottom of the purifiers, and are provided with orifices leading to the gas-conduits within the purifiers: these orifices are provided with baffles or fenders to prevent purifying material from entering them. —W. C. H.

Gas-Purifiers. S. Cutler, G. B. Cutler, and S. Cutler, jun., London. Eng. Pat. 6860, March 21, 1904.

To these purifiers there is attached an external chamber or pipe connected by branches with distributing conduits

within. The claims also include an arrangement of or slabs for carrying filtering material, used either singly or combined to form grids, with or without intermed and border gratings as described in Eng. Pat. 19,644 of (this J., 1903, 287). (Reference is also made to Eng. Pat. 14,970 of 1903, and 5395 of 1904.) —W. C. H.

Gas Purifiers: Impts. in. — S. Cutler, jun., London. Eng. Pat. 29,174, Dec. 31, 1904.

THE invention relates to purifiers constructed according to the Jager system, described in Eng. Pat. 19,644 of 1902 and 14,970 of 1903 (this J., 1903, 287). The inlet and outlet conduits of such purifiers are divided into two or more compartments, the purifier being thus divided into sections, through which the gas passes successively so that two or more kinds or grades of purifying material can be used in the same purifier. This is possible owing to the low pressure required to pass gases through purifiers fitted on the Jager system. —W. H. C.

UNITED STATES PATENTS.

Fuel. S. P. Sadtler, Philadelphia, Pa., Assignor to Car.-Ice Company, Camden, N.J. U.S. Pat. 782, Feb. 21, 1905.

A MIXTURE having approximately the following composition is claimed:—200 lb. of anthracite slack, 5 gal. of finely-powdered coke, 1 gal. of concentrated sulphuric acid (sulphite) residual liquor, and 5 lb. of aluminium sulphate. —W. H. C.

Fuel; Composition. — C. H. Carpenter, Assignor to J. L. White, South Bend, Ind. U.S. Pat. 782, March 7, 1905.

FRENCH PATENT.

Oils; Combustible Liquid Prepared from Heavy —, which can be used in Ordinary Burners without Clogging, L. Serpollet. Fr. Pat. 347,626, Nov. 3, 1904.

A mixture which may be used in ordinary (serpentine) burners without choking them is produced by incrusting with heavy tar oils about 10 per cent. of a mixture of kerosene and alcohol of the same density as the oil.—T. F. B.

II.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, PETROLEUM, AND MINERAL WAXES.

Tar from Lignite Tar Oil. G. Schultz and K. W. J. Gasbeleucht., 1905, 48, 125—131, 152—158, 182, 200—203.

The authors examined an oil-gas tar prepared from a lignite tar oil, which yielded the following results on distillation:—190°—220° C., 5.5; 220°—240°, 24.0; 240°—260°, 21.5; 260°—280°, 22.5; 280°—300°, 30.0; 300°—320°, 8.5; 320°—360° C., 1.5; residue, 1 cent. The tar was first subjected to a rough fractionation, 10,000 kilos. yielding 400 kilos. of water, 100 kilos. of light oil (sp. gr. 0.937), and 8100 kilos. of residue (1.166). The light oil and residue were then subjected by numerous fractional distillations, in some under reduced pressure, into a large number of fractions, which were tested by known methods for the presence of various compounds. The compounds detected were:—Water, benzene, heptane (?), toluene, three xylenes, ethylbenzene, styrene, pseudocumene, mesitylene, hydrindene (?), indene, coumarone, homologues, durenene, naphthalene, phenanthrene, anthracene, pyrene, chrysene, thiophen, thiotolene, cresols, pyridine and free carbon. The quantities of the more important constituents of the tar were as follows:—Benzene, 1.0; toluene, 2.0; xylenes, 1.3; oils below 150° C. and which resinify, 1.0; oils distilling between 150° and 200° C., 1.5; oils distilling between 200° and 300° C., 26.6; oils distilling between 300° and 360° C., 12.6; naphthalene, 4.9; crude anthracene, 0.58; "asphaltum," 22.0; free carbon, 20.5; bases, 0.3; bases, traces; and water, 4 per cent.—A. S.

Motor Spirit; Vaseline Oil; Vaseline. P. Adam. Bull. Soc. Chim., 1905, 33, 274—284.

Petroleum Spirit.—Owing to the great demand for motor spirit, the very light fractions, which were formerly burned in the stills or included in the next heavier grade of oil, are now collected separately, and the light products of the cracking process are also utilised as motor spirit. Petroleum spirit used as a solvent in the laboratory, for the presence of ethylenic hydrocarbons resulting from the cracking process, has the disadvantage of falsifying the bromine absorption value of the solutions. These hydrocarbons are easily eliminated by treatment with sulphuric acid, the ordinary light distillates being preferable for laboratory use.

Several samples of different kinds of spirit were examined by the author. One of them, dating from about 1850, distilled from crude oil mixed with light cracking

products, contained ethylenic hydrocarbons and always over 10 per cent. in one case, 140 per cent. of bromine, in the cold and the dark, without liberating hydrogen bromide. The ordinary light spirit of the present day (sp. gr. 0.655) has been treated with sulphuric acid, and does not absorb bromine, but is attacked by the latter, hydrogen bromide being liberated.

A sample of crude spirit, obtained by cracking, boiled at 60°—135° C., and had the sp. gr. 0.712; it was pale yellow in colour, and gradually deposited an amber-coloured resin. In presence of bromine it fumed, and absorbed 60 per cent. before liberating hydrogen bromide. Sulphuric acid absorbed 21.15 per cent. of the spirit, and turned black, whilst hydrochloric acid assumed a yellow tinge, and left a slight residue on evaporation. Nitric acid turned pink, and became hot, gas being liberated. On the other hand, a sample of ordinary light spirit, free from cracking products, boiled at 40°—130° C., and had the sp. gr. 0.675. It was of a pale yellow colour, slightly dichroic, and gave no reaction with mercury hydrogen sulphate. A 10 per cent. solution of bromine in carbon tetrachloride reacted only very slightly in the cold; and the bromine absorption was only 0.6 per cent., a crystalline white precipitate being formed, accompanied by liberation of hydrogen bromide. Sulphuric acid decolorised the spirit and acquired a brown coloration. The smell was improved, and the refined oil no longer combined with bromine, nor was there more than a slight liberation of hydrogen bromide. This spirit, refined with sulphuric acid and soda, is commercially known as gasoline. The winter product has the sp. gr. 0.64, and distils between 30° and 85° C., the sp. gr. of the summer product being 0.65, and the lowest b. pt. 40° C. It does not combine with bromine in the cold, and substitution proceeds slowly, though warmth and light accelerate the reaction. There is no reaction with mercury hydrogen sulphate.

The sample of vaseline oil examined had the sp. gr. 0.875, and distilled completely, without alteration, between 335° and 440° C. It was free from nitrogen, and practically free from substances absorbed by sulphuric acid; and bromine had but very little action in the cold, even in sunlight.

The best vaseline for pharmaceutical purposes melts between 35° and 39° C. Distillation converts it into crystalline paraffin-wax and liquid hydrocarbons, a little gas being evolved. The liquid portion absorbs bromine and contains ethylenic hydrocarbons, whereas the residue in the still does not. The gas consists chiefly of methane, the volume liberated being about 800 c.c. per 100 grms. of vaseline. The presence of paraffin-wax prevents the differentiation of pure and artificial vaseline by the aid of solvents, but the following tests furnish useful indications. Acidity is determined by warming the sample on the water-bath with an equal volume of neutral litmus tincture. The sample should volatilise completely, without liberation of acid vapours, when heated in a capsule. Heated with water and caustic potash, the filtrate obtained should remain clear on acidification. No coloration should occur when the sample is heated with sulphuric acid of sp. gr. 1.50, and the rise in temperature produced by agitation with nitric acid of sp. gr. 1.15 should not exceed 2° C. On the other hand, the thermal reaction furnished under this treatment by a sample composed of 25 parts of white vaseline, 60 of vaseline oil, and 15 of white ceresin, was 7° C. increased to 12° C. when the vaseline oil was replaced by "French neutral" oil. The viscosity affords a means of distinguishing natural vaseline from mixtures. Thus, the viscosity of vaseline free from paraffin is 680 at 60° C., 1 per cent. of paraffin lowering the result to 625, and 4 per cent. to 560, whereas artificial vaseline has the low viscosity of 390, and the "industrial" variety 300—360. In the absence of a viscosimeter, the vaseline may be warmed to the desired temperature in a wide tube, into which a dry pipette is then introduced, note being taken of the time taken by the vaseline to rise up to the mark in the pipette, and the result compared with that furnished by a sample of known purity.—C. S.

Oils, Lubricating; Testing the Behaviour of —, in the Cold. R. Hackel. XXIII., page 352.

ENGLISH PATENT.

Petroleum Oils, Process for Purifying — E. W. Wynne, Seacombe, Cheshire. Eng. Pat. 26,198, Dec. 2, 1904.

THE oils are mixed with: carbon, 4; "borax dry soap," 10; naphthalene, 2; camphor, 2; water, 1; alum, 10; pearl ash, 10; soda ash, 10; lead acetate, 1; and sulphuric (or hydrochloric) acid, 1 part per 1000 galls., and are treated with an air blast, filtered, and treated with a blast of ozonised air, which raises the flashing point and density of the oils. They are afterwards mixed with about 6 lb. each of potassium chlorate and naphthalene, and again treated with an air blast for 15–30 minutes. The apparatus consists of separate vessels, fitted with perforated air-pipes, for the various operations, in connection with an oil filter and filter for the ozonised air, means for conveying the oil from one vessel to another and a blower for the air blast.—C. S.

FRENCH PATENTS.

Pitch from Heavy Tar Oils; Process for the Manufacture of — Rud. Rötgers Chem. Fabr. f. Theerprodukte. Fr. Pat. 347,198, Oct. 28, 1904. Under Internat. Conv., July 1, 1904.

Pitch can be prepared from heavy tar oils by blowing air, preferably heated, through the heated oil, and distilling the product. Thus, a hard, brittle pitch may be obtained from tar oil of sp. gr. 1.079 by passing air, heated to 100° C., through the heated oil for 100 hours. The yield of pitch is stated to be about 40 per cent.—T. F. B.

Hydrocarbons such as Petroleum and Benzine; Solidification of — G. van der Heyden. First Addition, dated Oct. 26, 1904, to Fr. Pat. 346,860, Oct. 7, 1904.

THE emulsion of mineral oil and glue prepared as indicated in the principal patent (this J., 1905, 236) is mixed with tannin, or a substance containing tannin, and then melted and run into moulds. The amount of tannin should not exceed 10 per cent. of the weight of glue used. Good results are said to be obtained by using 6.7 parts of glue, and 0.67 part of tannin for each 100 parts of mineral oil.—T. F. B.

IV.—COLOURING MATTERS AND DYE-STUFFS.

Amines; Introduction of the CH₂OH and CH₂ Groups into Primary Aromatic —, and the *Preparation of Imine Bases*. E. Orloff. J. russ. phys.-chem. Ges., 1904 36, 1303–1311. Chem. Centr., 1905, 1, 674–675.

THE formamide of the base (aniline, naphthylamine, or the like) is treated with caustic soda to form the sodium compound, and the latter is heated with formalin. With the sodium compound of formanilide, the reaction proceeds according to the equations:

The product is a yellowish non-volatile oil, which on treatment with dilute acids is transformed into the imine base

The latter is insoluble in water, alcohol and ether, but soluble to some extent in acids and in a mixture of ether and chloroform. It can be purified by precipitation with potassium carbonate from acid solution, and is then obtained as a white powder which turns yellow on heating. With sodium nitrite it yields a nitroso compound which

forms a red azo dyestuff on treatment with an alkaline solution of β -naphthol. The imine base obtained from sulphanilic acid has the constitution

When treated with sodium nitrite it yields a nitroso compound which readily combines with β -naphthol in alkaline solution to form an orange-coloured dyestuff. —A.

Carbinols; Ketone Decomposition of —, G. Georgievics. Ber. 1905, 38, 884–886.

WICHELHAUS (this J., 1886, 318) effected a decomposition of Magenta and Methyl Violet by boiling them for several days with hydrochloric acid, and quite recently O. Fi and W. Hess (Ber., 1905, 38, 385) described a similar decomposition of nitro- and haloid derivatives of triphenylcarbinol by oxidation with chromic or nitric acid. The author found that Magenta and allied dyestuffs under certain circumstances undergo an analogous decomposition at ordinary temperature, especially if present in quinonoid colour bases. *p,p'*-Diaminobenzophenone always formed although in small quantities by treating Parafuchsine solution with caustic alkali. The reaction becomes complete in the presence of hydrogen peroxide, already at the ordinary temperature. The product obtained showed a yellowish-grey colour, m. pt. 24° C., yielded a hydrochloride soluble with difficulty and further identified by transformation into the corresponding dihydroxybenzophenone, according to Stædel and F. (see Ber. 1878, 11, 1748). Methyl Violet is still readily reacted upon than Magenta, yielding tetramethyldiaminobenzophenone, m. pt. 175° C., which was identified by its picrate, m. pt. 156–157°.—R. L.

Dibenzylacetone and Triphenylmethane. A. Baeyer. Ber. 1905, 38, 569–590.

THE author prepared tri-*p*-chloro- and tri-*p*-iodotriphenylcarbinol. To prepare the former compound *p*-chlorobenzene, obtained from *p*-chloro-aniline by diazotising with amyl nitrite and then reacting with potassium iodide, was treated with magnesium powder and then with the ester of *p*-chloro-benzoic acid, according to Grignard's reaction. The tri-iodo-derivative was prepared by diazotising paracosaniline with strong sulphuric acid and amyl nitrite in methyl alcoholic solution, isolating paracosaniline tridiazoniumsulphate

and treating this with a solution of iodine in aqueous potassium iodide. Both compounds are colorless crystalline solids, but their sulphates are strongly colored. That of the trichlorocompound forming brown prisms with slight green metallic lustre, whilst the tri-iodo-derivative forms a sulphate which closely resembles Magenta in appearance. Neither of these sulphates react with silver salts under normal conditions to form silver chloride or iodide, showing that they cannot be quinonoid salts of the formula—

Both tri-*p*-chloro- and tri-*p*-iodotriphenylcarbinol react readily with a mixture of aniline and aniline hydrochloride to form triphenylrosaniline (Aniline Blue).

The remainder of the article consists of theoretical considerations on the constitution of dyestuffs, more especially of the triphenylmethane series. The facts given lead to formulae of the type $(\text{C}_6\text{H}_4\text{N})_3\text{C} \cdot \text{O} \cdot \text{SO}_3\text{H}$ for colorless salts of *p*-substituted triphenylcarbinols. The author considers that colored triphenylmethane compounds contain an "ionisable carbonium value," which he represents by a zigzag line. Thus the sulphate of triphenylcarbinol has the formula $(\text{C}_6\text{H}_5)_3\text{C} \cdot \text{O} \cdot \text{SO}_3\text{H}$, whereas triphenylcarbinol itself, which is colorless, has the formula $(\text{C}_6\text{H}_5)_3\text{C} \cdot \text{OH}$. Phenolphthalein has the formula

coloured sodium salt is represented as

strated by these two examples the non-ionisable of the ordinary type may be converted into an ionisable carbonium valency" either by making the portion of the molecule more negative, as in the triphenylcarbinol sulphate, or the positive portion positive, as in the case of the sodium salt of phenolphthalein. Werner's coloured xanthone compounds are stated similarly, e.g.—

On the other hand the author considers such compounds as fuchsone, aurin and Homolka's base to be undoubtedly due to and to owe their colour to a characteristic carbonium double bond" which he denotes by a double line, e.g., fuchsone $(\text{C}_6\text{H}_5)_2\text{C}=\text{C}_6\text{H}_4\text{O}$; dimethyl-

aurin $(\text{CH}_3)_2\text{C}=\text{C}_6\text{H}_4$; aurin $(\text{HO.C}_6\text{H}_4)_2\text{C}=\text{C}_6\text{H}_4$; and Homolka's base, $(\text{NH}_2.\text{C}_6\text{H}_4)_2\text{C}=\text{C}_6\text{H}_4\text{NH}_2$. Coloured base of Magenta is formulated $(\text{NH}_2.\text{C}_6\text{H}_4)_3\text{C}=\text{Cl}$. Crystal base, and the dyestuff are formulated in an analogous manner; dibenzalacetone as $(\text{C}_6\text{H}_5.\text{CH}:\text{CH})_2\text{C}=\text{O}$ and its hydrochloride as either $(\text{C}_6\text{H}_5.\text{CH}:\text{CH})_2\text{C}=\text{Cl}$ or

$(\text{C}_6\text{H}_5.\text{CH}:\text{CH})_2\text{C} \begin{array}{l} \diagup \text{OH} \\ \diagdown \text{Cl} \end{array}$. The author also formulates quinazone, quinone-imine and azo dyestuffs in a similar manner, with the help of the conceptions of "azonium double bonds" and "ionisable azonium valencies." Thus he formulates Phenosafranine

phenol, $\text{O}:\text{C}_6\text{H}_4=\text{N}.\text{C}_6\text{H}_5$; and benzene, $\text{C}_6\text{H}_5 \text{---} \text{N}=\text{N}.\text{C}_6\text{H}_5$.—E. F.

Triphenylmethane Dyestuffs. Influence of the Position of Methyl- and Nitro-groups relatively to the Methane Carbon Atom on the Tinctorial Properties of —. E. F. Atzenstein and O. Runge. J. prakt. Chem. 1905, 71, 7—132.

The authors submit a very large amount of experimental material concerning the synthesis of triphenylmethane dyestuffs, more especially of those obtained by condensing tetramethyldiaminodiphenylcarbinol and tetramethyldiaminoditolylcarbinol with aromatic bases and nitro-compounds and oxidising the resulting leuco-compounds. Comparing their results and those of other investigators they arrive at the following general conclusions:—(1) A methyl group in *o*-position to the methane carbon atom of a triphenylmethane dyestuff does not adversely affect the length or shade; in certain instances, these are improved. When further methyl groups in the *o*-position to the methane carbon atom are introduced, however, the tinctorial character of the resulting dyestuff is in some cases almost entirely destroyed. This is more particularly the case when in two of the three benzene rings the methyl- and amino-groups are in the *m*-position, and the third in the *p*-position, relatively to one another. For example, the compound

on oxidation a dark-green dyestuff; the compound

gives a brighter, bluer and more intense dyestuff, whilst the corresponding compound which is methylated in each benzene nucleus in the *o*-position to the methane carbon atom yields a very weak bluish-green dyestuff. With the accumulation of systems of dialkylamino- and methyl groups in *m*-position to one another, the colour changes from violet to blue and finally to green. Thus the dyestuff from the compound

is violet, that from the compound

is blue, and that from the compound

is green.

The effect of a nitro-group on the shade of a triphenylmethane dyestuff is in itself small. In the *o*-position to the methane carbon atom, it influences the shade towards blue, in the *p*-position towards yellow and in the *m*-position, it leaves the shade unaltered. The presence of methyl- and alkylamino-groups in the *m*-position relatively to one another in two nuclei, and of methyl- and dialkylamino- or methyl- and nitro-groups in the *p*-position to one another in the third nucleus leads to worthless dyestuffs. Thus the leuco compounds formed by condensation of tetramethyldiaminodiphenylcarbinol with dimethyl-*p*-toluidine and with *p*-nitrotoluene yield valuable dyestuffs, whilst when the diphenylcarbinol is replaced by tetramethyldiaminoditolylcarbinol (with the methyl groups in *o*-positions to the methane carbon atom) the resulting dyestuffs are of no value. The authors find that when tetraethyldiaminodiphenylcarbinol is condensed with aniline in presence of hydrochloric acid, condensation takes place mainly in the *p*-position, but partially in the *o*-position to the amino group. In concentrated sulphuric acid solution the *o*-amino compound is mainly formed, accompanied by both *m*- and *p*-compounds. When tetramethyldiaminoditolylcarbinol is condensed with aniline, similar mixtures are obtained. The resulting dyestuffs are in this case dull. New leuco-compounds were prepared by condensing various aminotriphenylmethane leuco-compounds with 1,2,4-chlorodinitrobenzene, and oxidising, thus forming dyestuffs containing a dinitrophenylamino group. These dyestuffs show a greatly increased affinity for the animal fibre in an acid bath, but retain a certain basicity if the dinitrophenylamino group is in the *m*-position to the methane carbon atom. When it is in the *o*- or *p*-position, the basic properties of the dyestuff are destroyed.—E. F.

Apigenin: Second Synthesis of —. M. Breger and S. v. Kostanecki. Ber., 1905, 38, 931—933.

1.3.4'-TRIMETHOXYFLAVANONE

was brominated, forming 2.4.α-tribromo-1.3.4' trimethoxyflavonone,

On treatment with alcoholic potassium hydroxide solution, this formed 2.4.dibromo-1.3.4' trimethoxyflavone

which was converted by boiling with hydriodic acid into apigenin, which is 1,3,4'-trihydroxyflavone

—E. F.

3'-Hydroxyflavonol. A. Gutzeit and S. v. Kostancek. Ber., 1905, 38, 933—935.

By interaction of *m*-methoxybenzaldehyde and *o*-hydroxyacetophenone, the authors prepared 2'-hydroxy-3-methoxychalkone

By boiling with dilute sulphuric acid and alcohol, this was converted into 3'-methoxyflavanone

This was converted by means of amyl-nitrite and hydrochloric acid into an isonitroso-compound, which, on boiling with dilute sulphuric acid, formed 3'-methoxyflavonol

which dyes in light yellow shades on alumina mordant. By boiling with hydriodic acid it is converted into 3'-hydroxyflavonol

which also dyes on alumina mordant in light yellow shades. —E. F.

Quercetol; An Isomeride of —. S. v. Kostancek and F. Rudse. Ber., 1905, 38, 935—938.

2'-Hydroxy-3',4',3,4-tetramethoxychalkone, $(\text{CH}_3\text{O})_2\text{C}_6\text{H}_2(\text{OH}) \cdot \text{CO} \cdot \text{CH} : \text{CH} \cdot \text{C}_6\text{H}_2(\text{OCH}_3)_2$, was obtained by the interaction of the dimethyl ether of gallacetophenone and veratric aldehyde. By boiling its alcoholic solution with dilute hydrochloric acid, this compound was converted into 3,4,3',4'-tetramethoxyflavanone,

This was converted in the usual manner into an isonitroso compound, which, on heating with dilute mineral acids, formed 3,4,3',4'-tetramethoxyflavonol

By treatment with hydriodic acid the authors obtained from the latter compound 3,4,3',4'-tetrahydroxyflavonol

which is an isomeride of Quercetol. It is said to be an excellent mordant dyestuff, as was to be expected from the presence of two *o*-dihydroxy systems, and dyes on alumina mordant in orange-yellow to yellow, and on iron mordant in grey to black shades.—E. F.

Chromane, Synthesis of —. J. v. Braun and A. Stein-dorf. Ber., 1903, 38, 850—855.

CHROMANE,

the hydrogenised mother-substance of the chromanes, coumarins, &c., has never been isolated hitherto, though alkyl derivatives have been prepared. The authors benzoylate tetrahydroquinoline, and treat it with phosphorus pentachloride, forming *o*-γ-chloropropylbenzamide $\text{C}_6\text{H}_4(\text{C}_6\text{H}_5\text{CH}_2\text{CH}_2\text{CONHCO}_2\text{C}_6\text{H}_5)$. They saponify this, obtaining a salt of the corresponding non-benzoylated amine, from which by diazotising and warming with mineral acid, they obtain the corresponding phenol,

$\text{C}_6\text{H}_4(\text{C}_6\text{H}_5\text{CH}_2\text{CH}_2\text{OH})$. On warming this substance in alkaline solution it forms chromane, which is a white solid with an intense peppermint-like smell, somewhat soluble in hot water.—E. F.

Organic Dyestuffs; Absorption Bands shown by in the Ultraviolet. P. Krüss. Z. physik. Chem., 1905, 51, 257—296.

THE author has made numerous experiments on absorption of ultra-violet rays by a large number of organic dyestuffs, including triphenylmethane derivatives and some specially-prepared azo dyestuffs. It was found that organic dyestuffs exhibit, in the ultra-violet absorption-bands, of a smaller intensity and width in the visible spectrum. Dyestuffs belonging to the same group or class show, in general, similar absorption differences of constitution in dyestuffs of the same class causing only a more or less considerable displacement of the absorption bands. It is possible in many cases to determine the class to which a dyestuff belongs by means of its absorption spectrum. Aurin absorbs comparatively few ultra-violet rays. A layer 1 mm. of a solution of 1 mgrm.-mol. of aurin in 100 c.c. of water will allow, in addition to red and yellow rays, all violet and ultra-violet rays up to $\lambda = 285\mu$, to pass through. Such a solution, when used in combination with a strongly coloured cobalt glass, would, like the nitrosodiphenylamine, examined by Wood (this J., 1903, 440), be a light-filter almost opaque to the rays of the ultra-violet spectrum, whilst exhibiting great transparency for violet rays. The azo dyestuff from diazotised resorcinol is still more transparent for the extreme ultra-violet. A layer, 1 mm. thick, of a solution of 1 mgrm.-mol. of this dyestuff in 100 c.c. of concentrated sulphuric acid will allow the ultra-violet rays from $\lambda = 347\mu$ to $\lambda = 251\mu$ to pass through, while of the visible spectrum only the red and yellow are able to pass. The absorption spectra of many azo dyestuffs are different in concentrated sulphuric acid from those in aqueous or alcoholic solutions, probably owing to chemical change. Sulphonated azo dyestuffs show absorption spectra in sulphuric acid and in aqueous or alcoholic solutions. The absorption of ultra-violet rays increases with the number of "double linkings" in the molecule. The colourless bases obtained by the reduction of triphenylmethane dyestuffs all behave as colourless bodies, with strong absorption-bands, in the ultra-violet region of the spectrum. When exposed to light, they are again oxidised to the dyestuffs, the oxidation being caused by the ultra-violet rays which are absorbed. On further exposure to light, the colourless bases appear again more or less rapidly, not owing to reduction as is frequently stated, but by further oxidation (see Gros, this J., 1901, 888, 1104). The dyestuffs show to a greater degree the same absorption-bands in the visible as the colour-bases. It can be proved by exposure under suitable light-filters that the fading of dyestuffs depends in all cases upon the absorption of ultra-violet rays, but the extent of this absorption does not serve as a measure of the fastness to light, except in the case of dyestuffs of similar constitution. (See also this J., 1903, 134, 767; 1893, 823.)—A. S.

ENGLISH PATENT.

Azo Dyes; Mordant; Manufacture of —. H. Lake, London. From K. Ochler, Offenbach, Germany. Eng. Pat. 28,596, Dec. 28, 1904.

2,6-NITRO-AMINOPHENOL-4-SULPHONIC acid is diazotised and combined with *o*- or *m*-cresotinic acid. The resulting dyestuffs dye wool from an acid bath in reddish-brown shades which change to claret-red on subsequent treatment with a chromium compound. These dyestuffs are said to be very fast to light, milling and steaming. A dyestuff from *o*-cresotinic acid yields the bluer shade.—E. F.

UNITED STATES PATENT.

Dichlorodimethylfluorane [Pyron Dye-stuff] and Process of Making same. P. Julius, Assignor to Badische Anilin- und Soda-Fabrik, Germany.

Soda Fabrik, Ludwigshafen on Rhine, Germany. Pat., 785,003, March 14, 1905.

Pat. 342,518 of 1904; this J., 1904, 980.—T. F. B.

FRENCH PATENTS.

Dyestuffs; Process for the Preparation of new —. —. Farben- u. Textil-Chem. v. F. Bayer und Co. Fr. Pat. 347,376, Oct. 21, 1904. Under Internat. Conv., May 9, 1904.

DYOTISED benzidine-*m*-disulphonic acid or tolidine-*m*-sulfonic acid ($\text{NH}_2\text{C}_6\text{H}_3\text{SO}_3\text{H}$ 1:2:3) is combined with 1. of α -methylindole or 1-phenyl 3-methyl-5-pyrazolone or first with 1 mol. of α -methylindole and then with 1 of the phenylmethylpyrazolone. The resulting dye-dye wool from acid baths in yellow shades, fast to and washing.—T. F. B.

Dyestuffs; Preparation of New —. —. Farben- u. Textil-Chem. v. F. Bayer und Co. Fr. Pat. 347,655, Nov. 4, 1904.

DYOTISED-ACIDYL-*p*-PHENYLENEDIAMINE, for example 2-nitro-1-acetylaminobenzene, is diazotised, combined with a sulphonic acid of a dihydroxy- or aminodihydroxy-naphthalene, or with a substitution product of compounds, and the resulting dyestuff saponified. The products dye unmordanted wool fast black shades in acid bath. The shades obtained from dyestuffs dyed by saponification of the products from nitroacidyl-phenylenediamine and the following compounds are:—

1. Dihydroxynaphthalene-3,6-disulphonic acid, (chromic acid),—bluish black.

2. Dihydroxynaphthalene-2,4-disulphonic acid,—black.

3. Minonaphthol-3,6-disulphonic acid (in acid solution),—bluish black.

4. Minonaphthol-3,6 disulphonic acid (in alkaline solution),—greenish blue-black.—E. F.

Dyestuff [Azo Dyestuffs] Production of Red —. —. Allgemein- u. Soda- Fabrik. First Addition, dated Oct. 28, 1904, to Fr. Pat. 346,008, Sept. 2, 1904.

According to the original patent dichloraniline was used and combined with β -naphtholdisulphonic acid. According to this additional patent the dichloraniline is replaced by 3,4,6-trichlor-aniline, which is used below 10° C., by means of nitrosyl sulphate. The products produced from the product have a bright bluish shade similar to those produced from Xylidine Ponceau. The addition characterised by great fastness to and washing.—E. F.

Dyestuffs [Pyron Dyestuffs]; Manufacture of —. —. Bescho Anilin- und Soda- Fabrik. Fr. Pat. 347,546, Oct. 29, 1904.

ANILINE is condensed with 1 mol. of a monoalkylated phenol in presence of boric acid. The aniline of a kylaminohydroxybenzoylbenzoic acid formed in the reaction is saponified and then condensed with a di- or non-alkylated *m*-aminophenol to form rhodamine which may be alkylated in the usual manner.—E. F.

V. PREPARING, BLEACHING, DYEING, PRINTING, AND FINISHING TEXTILES, YARNS, AND FIBRES.

Fibres: Decomposition of —. —, by Fungoid Growth. —. Z. Farben- u. Textil-Chem., 1905, 4, 144—147.

Changes described have reference to raw cotton, free from contamination with added foreign matter, such as the presence of which is very liable to set up fermentation. The injurious substance was found to consist of "Pilzeellulose," a species of fungus resembling those in appearance, although not identical therewith, and giving a violet colour with iodine. It was found in sickly fibres only, and these on dyeing yielded

a darker colour than ordinary healthy fibres. From an examination of the seeds of various species of the cotton plant, it is shown, that the fungus in question is to be found present in the seed cells, and that such seeds when used for re-sowing are very apt to produce infected plants.

[D. B.]

Hydrosulphurous Acid: Formula of —. —, A. Bernthsen. Ber., 1905, 38, 1018—1056.

IN view of recent articles by Baumann, Thesmar and Frossard (this J., 1904, 1211; 1905, 237) and Prof'homme (this J., 1905, 89), the author points out that his formula for sodium hydrosulphite, $\text{Na}_2\text{S}_2\text{O}_4 \cdot 2\text{H}_2\text{O}$, has been fully confirmed by the preparation and analysis of the pure salt in the solid condition by Bazlen (this J., 1900, 244) and Moissan (this J., 1902, 1394). The possibility of sodium hydrosulphite, $\text{Na}_2\text{S}_2\text{O}_4 \cdot 2\text{H}_2\text{O}$ being a double salt, $\text{NaHSO}_3 \cdot \text{NaHSO}_2 \cdot \text{H}_2\text{O}$, which is decomposed into its components by water, is discussed, and it is shown that the evidence to hand, obtained from the preparation of the salt and also of zinc hydrosulphite is quite contrary to this view. The author protests against the name hydrosulphite being applied to compounds of the type RHSO_3 (or R_2SO_3) and suggests that such compounds be called salts of *sulphorylic acid*; the first known organic derivatives of this acid are the formaldehyde-sulphoxylates (Baumann, Thesmar, and Frossard's formaldehyde-bihydrosulphites).—A. S.

Hydrosulphurous Acid. M. Bazlen. Ber., 1905, 38, 1057—1068.

THE author, in conjunction with Bernthsen (this J., 1900, 244) has previously prepared pure sodium hydrosulphite, $\text{Na}_2\text{S}_2\text{O}_4 \cdot 2\text{H}_2\text{O}$. He has now carried out further work on compounds of hydrosulphurous acid. Sodium hydrosulphite. This salt may be separated from aqueous solution by other substances than sodium chloride, for example, by solid sodium bisulphite, and by a strong solution of sodium hydroxide. If both acid and normal salts of hydrosulphurous acid exist, as has been stated by Schützenberger (Comptes rend., 69, 196) and Grossmann (this J., 1898, 1109; 1899, 452), then different compounds should be obtained by precipitation with sodium bisulphite and hydroxide respectively, but it was found that the same salt, $\text{Na}_2\text{S}_2\text{O}_4 \cdot 2\text{H}_2\text{O}$, was separated in both cases. Precipitation with alcohol also yields the same salt, and it seems evident that Schützenberger's compound consisted of this salt in a very impure condition. Potassium hydrosulphite is obtained by precipitating a concentrated aqueous solution with alcohol. It has the composition $\text{K}_2\text{S}_2\text{O}_4 \cdot 3\text{H}_2\text{O}$, and is very unstable. Calcium hydrosulphite. Only one calcium salt could be separated from both acid and alkaline solutions. It has the composition $\text{CaS}_2\text{O}_4 \cdot 1\frac{1}{2}\text{H}_2\text{O}$. Zinc hydrosulphite has the composition ZnS_2O_4 . It is readily soluble in water (about 1:7), and has a great tendency to form supersaturated solutions. Zinc double salts. By "salting-out" zinc hydrosulphite solutions with soluble salts of the alkalis and alkaline earths, double salts are obtained. The zinc sodium salt appears to have the composition $\text{ZnNa}_2(\text{S}_2\text{O}_4)_2 + \text{Aq.}$, but it readily alters, probably with formation of a basic salt. The zinc-sodium, zinc-potassium, and zinc-ammonium salts are less soluble than the corresponding simple salts, but the zinc-calcium salt is more soluble, so that on treating a hydrosulphite solution containing zinc with calcium chloride solution, no precipitation of the slightly soluble calcium salt takes place, a fact which led Grossmann to assume erroneously the existence of an easily soluble acid calcium salt. Anhydrous salts. These are more stable than the salts containing water of crystallisation. The anhydrous sodium, calcium, and zinc salts can be prepared by heating the crystallised salt or a concentrated solution of the same, with strong alcohol for 4—2 hours at 65°—70° C., with vigorous agitation. The salt is then filtered off, washed with alcohol, and dried *in vacuo* at 50°—60° C. The anhydrous potassium salt is obtained by extracting the crystallised salt first with boiling acetone and then with boiling methyl alcohol, and finally drying *in vacuo* at 40—60° C.

Behaviour of Hydrosulphites to Aldehydes in presence of Alkali.—A solution containing 1 mol. of sodium hydro-

sulphite was shaken with 1 mol. of sodium hydroxide and 1 mol. of formaldehyde, and the mixture cooled and treated with an equal volume of alcohol, which caused precipitation of normal sodium sulphite. The alcoholic solution when evaporated *in vacuo* yielded a syrup, which, after standing for some time, set to a solid mass generally with a faint yellow colour. The product was purified by crystallisation from water and from alcohol, and was found to consist of formaldehyde-sodium sulphonylate, which has been obtained in other ways by Baumann, Thiesmar and Frossard (this J., 1904, 1211; 1905, 237; also preceding abstract) and by Reinking, Dehnelt and Labhardt (see following abstract). The reaction proceeds according to the equation:—

Formaldehyde-sodium sulphonylate is not precipitated from aqueous solution by calcium or barium chloride, but with milk of lime or barium hydroxide solution, it yields slightly soluble salts containing 1 atom of the alkaline-earth metal to 1 atom of sulphur. With sodium hydroxide a disodium salt is formed, which dissolves much more readily than the monosodium salt. With sodium bisulphite, formaldehyde-bisulphite is produced and sodium hydrosulphite is regenerated:

Other aldehydes form sulphonylates in a similar manner to formaldehyde. The author concludes from these results and from the fact discovered by Bernthsen that sodium hydrosulphite when oxidised with iodine, yields sulphuric and not polythionic acid, that in hydrosulphurous acid the two atoms of sulphur are united by an atom of oxygen. Hydrosulphurous acid may be regarded as a mixed anhydride of sulphurous and sulphylic acids. The aldehyde-sulphonylates are regarded as derivatives of an ortho-sulphylic acid H_2SO_3 or $\text{H}_2\text{SO}_2 + \text{H}_2\text{O}$. According to this view, formaldehyde-sulphonylate would, for example, be an inner anhydride of the constitution:

Aldehyde-Sulphurous Acid Salts and Hydrosulphurous Acid: Constitution of —. K. Reinking, E. Dehnelt und H. Labhardt. Ber., 1905, 28, 1069—1080.

THE authors' experiments confirm the view that the aldehyde-sulphurous acid compounds are esters of sulphurous acid, $\text{R.CH(OH).O.SO}_2\text{H}$, and not hydroxy-sulphonic acids, $\text{R.CH(OH).SO}_3\text{H}$. If formaldehyde-sodium bisulphite be reduced with zinc and acid in the proportions of 1 atom of zinc to 2 mols. of the bisulphite compound, formaldehyde-sodium hydrosulphite is produced, but if double the quantity of zinc be employed in presence of acetic acid, a product having a reducing power twice as great is obtained. Comparative experiments showed that true sulphonic acids yield on reduction sulphinic acids, which have no reducing action on Indigo Carmine, whereas esters of sulphurous acid give products having reducing properties similar to those of the compound from formaldehyde-sodium bisulphite. These results lead the authors to express the reduction of formaldehyde-sodium bisulphite by the equation:—

the hydroxymethyl group remaining unchanged, whilst the residue of the sulphurous acid, $\text{HO.SO}_2\text{H}$ is reduced to the residue of a new acid, HO.SO.H , named by the authors sulphylic acid. (The reduction product of formaldehyde-sulphurous acid is named empirically formaldehyde-sulphylic acid, and its salts, formaldehyde sulphonylates.) Formaldehyde-sodium sulphonylate has already been described by Baumann, Thiesmar and Frossard (this J., 1904, 1211; 1905, 237) under the name of formaldehyde-sodium bisulphite. It reacts with aromatic amines, but the products, in the dry condition, are readily decomposed on exposure to the air. The product from *o*-toluidine has, however, been prepared and analysed, giving results corresponding with the formula

Constitution of Hydrosulphurous Acid.—From the ease with which sodium hydrosulphite is decomposed by

formaldehyde, and from the nature of the product formed, the authors conclude that hydrosulphurous acid is a mixed anhydride of sulphylic and sulphurous acids. The reaction between sodium hydrosulphite and formaldehyde is represented by the equation:—

and the regeneration of sodium hydrosulphite by the action of sodium bisulphite on formaldehyde-sodium sulphonylate by the equation:—

and Treating Textiles with a Liquid in Circulation; Machine for —. G. de Keukelaere. Fr. Pat. 347,677, Nov. 5, 1904.

The machine is made on the principle of a centrifugal, perforated basket of which contains the material to be treated, supported in suitable receptacles: for instance, the material is wound on perforated bobbins may be employed. The basket is provided with a double bottom; the upper part is pierced with conical holes, into which the shaped bobbins holding the bobbins fit. The space between the bobbins constitutes a liquid-distributing chamber, the liquid being supplied by a pump, through a pipe which is connected with an opening in the lower bottom of the basket; the liquid thus passes up through the material, and is then impelled off the perforated basket into the main vat, whence it is pumped off. The shaft to which the basket is fixed is vertically displaced by means of a wedge-shaped support operated by a lever, so that, when the treatment with liquid or liquids is completed, the basket may be raised, disconnected from the liquid-supply pipe, when it is free to be rotated, thus constituting a centrifugal drying apparatus.—T. F. B.

under Pressure; Apparatus for —, which can be regulated. L. Déré. Fr. Pat. 347,809, Nov. 11, 1904.

Paper and Other Materials in the Web; Method of Figuring Continuous —. G. Hennessen and P. Spä. München-Gladbach, Germany. Eng. Pat. 26,532, Dec. 6, 1904.

THE object of this invention is to produce designs upon paper and other materials by rendering certain parts of the surfaces of these smooth and glossy, while leaving other parts more or less rough and lustreless. To this end, the paper, &c., is passed in a continuous sheet or web between a friction roller *c* (see figure) and an "elastic roller" *b*, composed of or covered with cotton, paper, leather, asbestos, indiarubber or other suitable material. The design to be reproduced is engraved upon a roller *a*, from which it is constantly impressed upon the surface of the roller *b*, as the two rollers revolve in contact with each other. The surface of the paper, &c., which is to be ornamented being turned towards the friction roller, those parts of the paper, &c., which lie upon the raised portions of the surface of the roller *b*, as this revolves under the friction roller, are made smooth, the design temporarily raised by the roller *a* upon the surface of the roller *b*, being at the same time effaced. The rollers *a* and *b* rotate with the same surface speed, which is less than that of the roller *c*.—E. B.

VII.—ACIDS, ALKALIS, AND SALTS, AND NON-METALLIC ELEMENTS.

Sodium and Magnesium Sulphates; Equilibrium between —. R. B. Denison. Paper read before the Faraday Society, Jan. 30, 1905.

At 25° C., the only double salt hitherto obtained is astrakanite $\text{Na}_2\text{Mg}(\text{SO}_4)_2 \cdot 4\text{H}_2\text{O}$; whilst at higher temperatures loeweite $\text{Na}_2\text{Mg}_2(\text{SO}_4)_4 \cdot 5\text{H}_2\text{O}$ and vanthoffite $\text{Na}_6\text{Mg}_2(\text{SO}_4)_4$ are known. The author has endeavoured to obtain the sodium analogue of langbeinite, $\text{K}_2\text{Mg}_2(\text{SO}_4)_2$. No evidence of its existence, however, could be obtained. A solution of astrakanite with excess of magnesium sulphate and one of magnesium sulphate with excess of astrakanite, shew the same vapour pressure, both being saturated with astrakanite and magnesium sulphate; whereas if langbeinite were formed, the solution saturated with it and astrakanite would probably have a different vapour pressure from that saturated with langbeinite and magnesium sulphate. Moreover, though dilatometric experiments with a solution of magnesium sulphate and astrakanite in molecular proportions showed that the system undergoes a change at 58° C., while the dehydration of astrakanite and formation of loeweite occurs at 71° C., yet on evaporation at 58° C., no langbeinite, only loeweite crystallised out. The transition temperature is thus apparently lowered from 71° to 58° by the excess of magnesium sulphate.—J. T. D.

Thiosulphates; Time required for the appearance of a Precipitate in the Decomposition of —. G. Gaillard. Comptes rend., 1905, 140, 652—653.

As the concentration of the thiosulphate solution to which a given reagent is added is increased, the interval between the addition of the reagent and the appearance of turbidity is lessened. The curves representing the connection between the two variables are hyperbolic in general character. When the reagent is varied the curves obtained vary in position and form, though maintaining a general likeness; and when the reagents are related, as, for

example, hypochlorous, chloric, and various acids, hydrochloric, hydrobromic and hydroiodic acids, or when the same reagent acts on related salts as ammonium, sodium, and strontium thiosulphates, the curves obtained are similar, and differ only in their distance from the axes. When the same solution of thiosulphate is used, the interval increases with the quantity of a given reagent added.

When other substances are mixed with the thiosulphate solution before adding the reagent, the appearance of the precipitate is usually retarded; and where the added substances are related (chloride, bromide, iodide, or salts of magnesium, zinc, and cadmium) the retardation is usually greatest with the element of highest atomic weight. In many cases, if a substance be added to the precipitating acid, it produces no effect, whilst if it be added to the thiosulphate solution it causes retardation. Diluent diluents (water, glycerin, alcohol, of the thiosulphate solution retard the action unequally; alcohol more than glycerin, glycerin more than water.—J. T. D.

Bleaching Powder: Pink Coloration of —. N. Targui. *Gaz. chim. ital.*, 1905, 34, 466–468. *Chem. Centr.*, 1905, 1, 584.

The pink coloration which is produced when bleaching powder or a hypochlorite is acted upon by carbon dioxide, or simply warmed to a temperature below 50° C., has been attributed to the presence of small quantities of manganese, which, by the oxidizing action of the hypochlorite, are converted into permanganate. The author found, however, that the residue obtained by the evaporation of solutions of bleaching powder which had been coloured by carbon dioxide or by heating contained iron but no manganese. The coloration is therefore attributed to the presence of iron, probably in the form of calcium ferate. Bleaching powder, which is free from iron, is not coloured pink by carbon dioxide, but the coloration appears if a small quantity of an iron salt be added. The iron present in bleaching powder cannot be determined by the permanganate method.—A. S.

Phosphorus: Manufacture of —. W. Hempel. *Z. angew. Chem.*, 1905, 18, 401–402.

NEUMANN, in criticising the author's paper (this J., 1905, 195), has misunderstood him in several places. An electric resistance furnace, not a carbon arc, was used, as being more certainly regulated and controlled; but the author has not suggested that this should be used on the large scale. With metaphosphoric acid the yield of phosphorus that can be collected was poor, but the author did not say that "absolutely negative results" were obtained; this process was not farther investigated, because Wohler's gave such good results. The author considers that on the large scale internal arc-heating will be more economical than externally fired retorts, as the slow heat-conduction through the retorts will more than compensate for the lower cost of fuel. Further experiments in the author's laboratory have shown that Wohler's process, using arc-heating, is by far the best method of preparing phosphorus. If Neumann only obtained by this process 60 per cent. of the theoretical yield, his furnace must have been incorrectly constructed or the process improperly carried out.—J. T. D.

Arsenic: Production of Yellow —. —, by means of the Electric Arc. A. Stock and W. Siebert. *Ber.*, 1905, 38, 966–968. (See also this J., 1905, 28.)

LARGER quantities of yellow arsenic can be obtained by the action of an electric arc between arsenic electrodes under carbon bisulphide. The arsenic volatilises and is condensed and dissolved by the carbon bisulphide. The anode need not necessarily be of arsenic, but might be a carbon rod. Fused arsenic becomes very brittle in cooling; it is therefore difficult to make the anode from the pure metal. The authors employed an alloy of arsenic and antimony. In the arc the antimony is reduced to a very fine black powder, absolutely insoluble in carbon bisulphide. The operation was carried out in a beaker containing 500 c.c. of the solvent, the whole placed in a larger vessel filled with water and ice. Using a current

of 12 amperes, 5 grms. of the alloy were decomposed in 5 minutes, when the experiment was interrupted to let the solution to cool down. Working for a 1 per cent solution gives best results. The solution, separated the water and filtered, is colourless, but turns yellow sometime. At –80° C. all the arsenic crystallises out of the solution. By evaporation of the solution the modification of arsenic almost free from sulphur is obtained.—R.

Chlorates and Perchlorates; Electrolytic Manufacture. — P. Corbin. Fr. Pat. 339,251, Dec. 31, 1903.

The invention relates to the manufacture of chlorates by electrolysis of neutral alkali chlorides. Resin is added in small quantities in the presence of compounds of the alkaline earths, and, in addition, dilute perchloric acid is introduced into the solution during intervals in the electrolytic treatment of the same ion.—B. N.

Chlorides; Purification of —. Soc. Badische Anilin u. Soda Fabrik. Fr. Pat. 347,373, Oct. 21, 1904.

Barium cyanides are distilled with a solution of an ammonium salt, preferably under diminished pressure, and the onium cyanide formed is received in an acid or an alkaline solution, as may be required. For example, sodium cyanide containing cyanate, is dissolved in water to which ammonium chloride is added, and on distilling, the distillate is received in a solution of sodium hydroxide, the sodium cyanide solution obtained being subsequently concentrated under diminished pressure. In the case of crude barium cyanide, this is suspended in water through which carbon dioxide is passed, and sodium carbonate is added to the cleared liquid in a certain proportion. The solution is distilled *in vacuo* until all the ammonium cyanide has passed over, which is then received in caustic soda solution.—E. S.

Hydrosulphites; Production of — Dry and quite Stable. — Soc. Badische Anilin und Soda Fabrik. First Addition. Dated Oct. 25, 1904, to Fr. Pat. 341,718, of March 28, 1904. (This J., 1904, 900.)

An alternative to the process of dehydrating hydrosulphites, described in the main patent, they are, under addition, treated in hot saturated solution with an oil, ether, or other liquid, capable of abstracting water. For instance, to 3 volumes of 95 per cent. alcohol at about 70° C., 1 vol. of a saturated sodium hydrosulphite solution is added, and the mixture is stirred for some time. The deposited salt may be filter-pressed, washed with a volatile liquid and dried in a vacuum.—E. S.

Hydrosulphites; Production of — Dry and quite Stable. — Soc. Badische Anilin und Soda Fabrik. Second Addition, dated Nov. 7, 1904, to Fr. Pat., 341,718, of March 28, 1904. (This J., 1904, 900.)

Under the processes described in the main patent and in the first addition thereto (see the preceding abstract) hydrosulphites may, under the present addition, be treated, under various specified conditions, with caustic alkalis. According to one of the examples given, 100 parts of concentrated sodium hydrosulphite and 100 parts of sodium hydroxide solutions, are mixed with 30 litres of alcohol at a stated temperature. Hydrosulphite free from water of crystallisation is quickly deposited and may be collected by filtration.—E. S.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

Portland Cement; Relation between the Solubility of Calcium Sulphate and the Hydration of Portland Cement. — P. Rohland. Z. angew. Chem. 1905, 18: 327—339.

The author has shown that the increase of the solution pressure, and the acceleration, diminution, and retardation of the velocity of hydration stand in close relation to one another, and consequently the velocity of hydration is dependent upon the size of grain. From the relation between size of grain, solubility and velocity of hydration, the conclusion can be logically drawn that the body to be hydrated must first go into solution, before the reactions of hydration can take place.

The size of grain of the dihydrate of calcium sulphate is of importance in the case of Portland cement, the rate of hydration of which is retarded by this "negative catalytic agent." By a number of observations it has been shown that for every Portland cement the addition of a determinate quantity of gypsum is necessary to reduce the rate of hydration to a desired amount, so that almost every Portland cement in this respect behaves individually—the reason depending upon the constitution of the cement, which again influences the solubility.

Since both the hemihydrate and the anhydrous modification of gypsum first go into solution before the hydrating reaction occurs, it must be concluded that from time to time before the solution product is reached, hydrating molecules exist in the solution.

Jones and Getmann state that since hydrates form in concentrated solutions, a portion of the solvent combines with the dissolved substance, and that such solutions therefore are more concentrated than they would appear to be from the amount of dissolved substance; further that those bodies which crystallise with the largest crystal masses, combine probably under otherwise similar conditions in solution with the largest amounts of water; and finally that the hydrates in solution at higher temperatures must be unstable, so that for their formation a greater concentration is necessary.

It may be noted that calcium sulphate attains a maximum solubility in dilute solutions of electrolytes such as sodium chloride, magnesium chloride, sulphuric acid, &c. which N. Orlov explains by the formation of complexes. The author has established the fact that the maximum solubility of gypsum in the solutions mentioned corresponds with the maximum rate of hydration; in pure water, also, between 35°—40° C. the maximum amount of solubility corresponds with the maximum rate of hydration.—W. C. H.

[Cement] Kilns; Rotary —. T. Don, Upper Beeding, Sussex. Eng. Pat. 8973, April 19, 1904.

In order to tighten up each ring of firebrick lining, iron keys or wedges are inserted between two or more blocks, and by means of a screw and yoke resting on the bricks, the wedges are drawn towards the centre of the kiln and the space behind the wedge packed with, say, metal or firebrick. A portable arch piece is employed to temporarily support the firebricks which form the upper portion of each ring of the lining, and is provided with wedges or screws by which the blocks can be thrust into position and retained there until the whole ring is tightened up. Strips or plates of metal are inserted between the blocks, and

extend beyond them radially into the kiln, for and a series of points to which the lining of cement clinker can be fastened. To repair thin portions of this lining of clinker, finely-divided iron or steel filings may be employed, and can be introduced into the kiln while it is being cooled, or by being blown in through a tube. —W. C. G.

Rocks, Krollin-containing and other: Method and Apparatus for Decomposing — by Washing and Separating their Constituents. R. Frugier. First Addition of Nov. 8, 1904, to Fr. Pat. 336,190, of Nov. 9, 1903.

The rock to be treated is fed into the annular space *c*, and there is subjected to the action of water, which is introduced through the pipe *b*, which also serves for the removal of the separated sand, which passes through the lattice-work *e* surrounding the rock. To assist the action, the outer vessel *g* revolves at varying speed around the axle *a*; or else this outer vessel is fixed, and a vertical agitator rotates around the axle in the space outside the lattice-work. —A. G. L.

X.—METALLURGY.

Steel: Structure of Hardened — I. Reagen. Distinguishing the Different Phases. W. Kur. J. russ. phys.-chem. Ges., 1905, 36, 1524—1539. Centr., 1905, 1, 839.

The author has studied the behaviour as etching agents solutions of nitric, hydrochloric and picric acid in different fatty alcohols, with and without addition of organic nitro compounds. The results obtained show the difference between austenite and martensite, and other fine differences of microstructure can be defined by using the following solutions as etching agents: —(1) A 4 per cent. solution of nitric acid in cumyl alcohol; (2) a mixture of one part of solution (1) with three parts of a saturated solution of nitric acid in acetic anhydride; (3) a mixture of three parts of a per cent. solution of hydrochloric acid in isomyl alcohol with one part of a saturated solution of nitric acid in isomyl alcohol; and (4) a mixture of one part each of nitric acid in acetic anhydride. —A. S.

Ammonia-Copper Cyanide Process: Note on the — H. L. Sulman. Inst. of Min. and Metall., March 10, 1905.

ALKALI cyanides mixed with certain quantities of ammonia and a cupric salt are amongst the most rapid and efficient solvents of gold, when freshly prepared; the rate depending initially upon the instability of cupric cyanide. If therefore potassium cyanide solution together with a working excess of ammonia be added to an ore containing a sufficient amount of cupric salt to saturate the former, it will, while liberating some cyanogen, be converted into compounds of the cuprammonium cyanide type, which are capable of yielding further supplies of nascent cyanogen available for dissolving gold, until the final stage, marked by the appearance of small bright green acicular crystals of ammonium di-cuproso-cupric cyanide having composition $4\text{NH}_3 \cdot 2\text{Cu}_2(\text{CN})_2 \cdot \text{Cu}(\text{CN})_2$, insoluble in cold water and but slightly soluble in dilute ammonia. (See also this J., 1905, 199.) —J. H. C.

Gold Slimes: Fluxing of — C. E. Meyer. J. Metall. and Mining Soc., S. Africa, 1905, 5, 168—19.

THE author has effected considerable improvement in the amount of flux required, and the proportion of gold recovered from gold slimes, by using a flux of borax and manganese dioxide. Analysis of the slimes shows they contained rather more than enough silica to flux the zinc oxide present, with formation of the silicate. Zinc oxide, the excess of silica rendered the slag more fluid. Two per cent. of borax was found to be sufficient to flux the oxides, 17 per cent. being mixed with the slime, and the remaining 3 per cent. added as a cover. An addition of 2 per cent. of manganese dioxide was found to effect an improvement in the fineness of the resulting bar of metal. It is recommended that the slimes be carefully purified with a view of obtaining, as far as possible, a product of constant composition, and that in particular, sulphates be completely removed. —A. S.

Aluminium as an Antidote in Acute and Chronic Mercurialism [also Detection of Mercury]. N. Tarugi. Chim. ital., 1905, 34, 486—492. Chem. Centr., 1905, 1, 757—758.

By the action of mercury vapour on metallic aluminium, aluminium amalgam is formed, and the reaction can serve as an extremely sensitive test for mercury. To a solution of 1 part of mercuric chloride in 1000 parts of water, be acidulated with dilute sulphuric acid, the solution boiled for about 10 minutes in contact with a spiral of aluminium wire, and the latter then withdrawn, with filter paper, and exposed to the air, the characteristic coating of aluminium amalgam can be perceived. It is stated that 0.0001 mgrm. of mercury can be detected in this manner. Aluminium amalgam can be heated to 200° C. in presence of metallic aluminium, without evolution of mercury vapour escaping.

This action of aluminium in fixing mercury can be applied for the purpose of preventing the injurious

reury vapours in mines, &c. The author has a respirator (patented in Italy, Austria and Spain) in which the air charged with mercury is caused to pass through layers of aluminium gauze before being breathed.

—A. S.

Cobalt and Nickel; Physical Characters of Pure —. Copaux. *Comptes rend.*, 1905, 140, 657—659.

The author has carefully prepared and fused pure cobalt and nickel, containing not more than 0.025 to 0.05 per cent of non-metallic impurities, and determined some of the physical constants of the metals. His results, along with previously accepted figures, are as follows:—

	Observed Values		Former Figures.		Units.

Adsorption in —. W. H. Weed. *Eng. and Mining J.*, 1905, 79, 364.

The author refers to the discovery by E. Kohler (*Z. prakt.*, 1903, 49) that colloidal substances, such as clays, possess the power of extracting metals from very dilute solutions. For example, if a 1 per cent. aqueous solution of cuprammonium sulphate be passed through a filter coated with kaolin, the copper is retained in the form of copper oxide by the filter, whilst the filtrate contains ammonium sulphate. This power of "adsorption" by clays is considered by Kohler to account for the position of ore in clayey ore-bodies such as the bearing limestone of Commern, Germany, and the bearing sandstone of Freihung. The author points out that this theory may also throw some light on the occurrence of "orn-silver" in the kaolins of the Broken Hill silver mine, and also on the association of specially rich copper ores with clays in many copper mines. In some experiments with copper solutions, it was found that 90 per cent. of the copper could be extracted by means of crushed kaolin.

Iron, Ingot Steel, and the like; Decaridation of —. Imray, London. From the Soc. Anon. pour l'Industrie de l'Aluminium, Neuhausen, Switzerland. *Eng. Pat.* 10,902, May 11th, 1904.

The molten metal is run into a second furnace, electric or otherwise, and cooled down until the oxidation products are separated. It is then heated up under a neutral atmosphere, the further necessary ingredients such as carbon, manganese, silicon, chromium, &c., being added before being cast into ingots.—J. H. C.

Improved — [for Electric Conducting Wires]. Process for Manufacturing the same. W. P. Thompson, London. From U. T. fu Carlo, E. F. di Tito, Pollak and Rothschild, Paris. *Eng. Pat.* 19,251, Sept. 6, 1904.

The alloy consists of copper, preferably electrolytic, 95 kilos.; silver, 800 to 1000, 0.2 to 0.3 kilos.; manganese, 0.6 to 1.5 kilos.; aluminium, 4.8 to 10 kilos.; amorphous phosphorus 0.005 to 0.015 kilo. The temperature of fusion of the components is about

1100° C., that of the alloy is lower. The copper is melted first in a crucible, the ingots of manganese having been heated are then added, next the phosphorus previously combined with a portion of the copper is wrapped in paper and placed in a cap or cover over the molten copper so that when the paper burns it may fall into the molten copper, and finally the silver, which has been alloyed with the aluminium, is added.—J. H. C.

Furnaces; Impts. in Reverberatory —. M. Drojecki, Stawachowiec, Russian Poland. *Eng. Pat.* 25,796, Nov. 26, 1904.

The furnace is divided above the hearth bottom by one or

more partitions extending from one side-wall to the other, and built of, or covered with non-conducting material, whereby the flame is prevented from spreading over the arch and compelled to pass beneath the partition, so producing a prolongation of its path, widening of the combustion zone, and consequent increased utilisation of heat, with better protection of the arch. The partitions may be water-cooled.—J. H. C.

Amalgamators; Impts. in —. B. A. Langridge, Boulder, Colo., U.S.A. *Eng. Pat.* 28,490, Dec. 27, 1904.

The apparatus is formed of a body section 11, divided into two compartments by the partition 27, and a base section 10, fastened together by locks on the staples 17. The ore pulp is fed on to the spreader-plate 24, which

distributes it over the perforated plate 29, through which it falls first on to the amalgamated copper rollers 30, and then through the amalgamated copper rollers 32. The pulp then passes through the amalgamated, soft-covered copper shavings 37, held between the perforated copper plates 35 and 36, and finally through a trip of lead of the funnel 37a, and the bowl 38, the latter and the funnel 37a being provided with overflow outlets 43 and 44 respectively. —A.S.

(A.)—ELECTRO-CHEMISTRY.

Platinum: Electrolytic Solution of — in Sulphuric Acid. A. Brochet and J. Petit. Comptes rend. Acad. Sci. Paris, 140, 655–657.

THE results of the authors' experiments show that (1) a current of varying intensity causes the solution of platinum in sulphuric acid; (2) an alternating current has no specific action as such, due to change of direction; (3) when the solution contains no oxidising agent, the solution of metal at the anode is exactly equivalent to the deposition at the cathode; (4) an oxidising agent does not produce a higher oxide of platinum, the solution of the metal; it simply prevents the reduction of the platinum, becoming itself reduced, and the metal remains dissolved, at least till its concentration reaches a certain limit; (5) if a continuous current is superimposed upon an alternating current, the rate of dissolution from the (continuous) anode, and deposition on the (continuous) cathode. The resultant effect of the alternating current is zero, and the uniform corrosion current behaves as though it were a variable continuous current. —J. T. D.

Kjellin's Process for the Electrical Production of —. V. Engelhardt. Stahl u. Eisen, 1905, 25, 148—205—212, 272—278.

author describes the Kjellin electric furnace and method of working it, and gives results which have obtained with this process for the electrical pro- of steel. He then makes a comparison between Kjellin process on the one hand and other methods ufacturing steel on the other. For the production l of special quality the Kjellin process is quite as t as the crucible method, and is also cheaper, the melting and of crucibles being at least 20—40 M. of steel by the crucible method as compared with 18—22 M. by the Kjellin process (the cost of electric being taken as 2 pig. per k.-w.-hour.).

with regard to the production of Martin steel, the process appears to be quite capable of competing e Siemens-Martin furnace. The cost with the Martin is from 75—80 M. per ton of steel by the basic and 85—88 M. by the acid process. With a Kjellin of 736 k.w. capacity, the cost per ton of steel is in the following table:—

	cold cold 30 tons	molten cold 30 tons
energy, reckoning at 2 pig. per k.-w.- with a consumption of 0.6 k.-w.-hour lo. when cold pig iron is used, and of -w.-hour with molten iron	12.00	10.00
s. of pig iron at 55 M. per ton	13.75	13.75
s. of iron scrap at 45 M. per ton	35.55	35.55
of ferro-silicon at 115 M. per ton	1.38	1.38
	1.48	1.23

Grease [from Waste]; Centrifugal Machine for Extracting — Oil and Waste Saving Machine Co. Fr. Pat. 347,408, Oct. 25, 1904.

SEE U.S. Pat. 773,220 of 1904; this J., 1904, 1079. —T. F. B.

Soap; Process and Apparatus for Rapid Moulding of — F. Holoubek. Fr. Pat. 347,585, Oct. 31, 1904.

THE hot liquid soap is conducted into moulds which are open at the sides, the chambers being completed by refrigerating boxes through which passes a current of cold water. The moulds and refrigerating boxes are packed in alternate vertical layers so as to form a battery, which rests on a movable carriage. Claim is also made for a horizontal channel for the introduction of the soap, this being formed by connecting corresponding extensions at the top of each mould and cooling box. A vertical pipe from this communicates with the interior of each mould. —C. A. M.

XIII.—PIGMENTS, PAINTS; RESINS, VARNISHES; INDIA-RUBBER, Etc.

(A).—PIGMENTS, PAINTS.

Barytes; Bleaching [Decolorising] — E. Higgins, jun. Eng. and Mining J., 1905, 79, 465; from Eng. News, Feb. 23, 1905.

THE crushed barytes ore is washed and then treated with sulphuric acid of 20–30° B. in circular wooden tanks lined with sheet lead. A tank 4.5 ft. high and 8 ft. in diameter will contain about 14 tons of the crushed mineral when charged to a height of 3.5 ft. Each tank is provided with a coil of 1.5- or 2-in. lead pipe, closed at the end and provided with perforations; this coil can be connected at will with a supply of water or steam. The cost of heating and agitating the mixture of ore and acid may be considerably reduced by forcing in, by means of an injector, a mixture of air and steam instead of steam alone; the temperature is maintained at about 200° F. (93° C.). The mineral freed from discolouring iron compounds by this treatment, is washed free from acid and particles of clay, dried, and ground first by rolls and then by burr-stones. The "bleaching" is finished as a rule in 24 hours, and from 30–40 tons of the barytes (barium sulphate) can be milled in 24 hours by 12 burr-stones of 3.5 ft. diam. Barytes ore containing manganese

dioxide is ground, mixed with sodium nitrate, and sulphuric acid, heated in a furnace, and the product purified by washing and settling. *Blanc fixe* is produced by mixing finely-ground barytes with one-fourth volume of coal, heating the mixture to a high temperature, treating the product with water and precipitating barium sulphate from the filtered solution by the action of sulphuric acid. —A. S.

UNITED STATES PATENT.

White Lead; Process of Manufacturing — W. H. Rowley and J. H. Montgomery, Assignors to J. C. Shaughnessy, all of St. Louis, Mo. U.S. Pat. 782,821, March 14, 1905.

MOLTEN lead is atomised and oxidised, and the lead-laden particles are subjected to the oxidising action of moisture in a closed chamber, in which they are treated with jets of water. The particles are then ground in water, and the liquid is stirred to prevent settling. Finally the material is subjected to the action of carbon dioxide gas, to produce lead carbonate. —E. S.

FRENCH PATENTS.

Monazo Dyestuff [Azo Dyestuff]; Production of Red specially suitable for the Manufacture of Lakes. Br. Pat. 213,111, Anilin und Soda Fabr. Addition to Fr. Pat. 347,408, Sept. 2, 1904. IV., page 329.

White Lead Pigment; New —, and Process of Manufacturing the same. Gebr. Heyl and Co., G. and A. Wultze. Fr. Pat. 347,311, Oct. 21, 1904. Internat. Conv., June 11, 1904.

THE new pigment is produced by treating a dilute aqueous solution of normal lead acetate with carbon dioxide under pressure. It contains on the average 16 per cent. of carbon dioxide, and thus consists almost entirely of normal lead carbonate. It is claimed to be superior in quality and covering power to ordinary white lead. —A. S.

XIV.—TANNING, LEATHER, GLUE, SIE.

Albumin Compounds; Hydrolysis of — II. C. Zdz. H. Skraup. Monatsh. f. Chem., 1905, 28, 243.

SOME time ago the author discovered certain amino-acids, such as diamino-glutaric, diamino-adipic and others among the products of the hydrolysis of casein by concentrated hydrochloric acid. He has now hydrolysed gelatin under similar conditions, and the following differences in the products of hydrolysis of casein and gelatin, besides those already known; casein and caseinic acids which are produced from casein in considerable quantity, as well as diamino-hydroxy-acids and hydroxy-amino-succinic acids could not be obtained from gelatin. Diamino-glutaric acid, on the other hand, is contained in gelatin in far greater quantity than in casein. Gelatin also yielded a new acid $C_{12}H_{25}N_5O_7$ not obtainable from casein and termed by the author "Leimsäure." The author attributes these results to which some alterations in the mode of working are due, to differences in the constitution of gelatin and casein. The hydrolysis was carried out by treating the gelatin for 12 days with dilute hydrochloric acid at 60° C., until the specific rotation became constant. The solution was then subjected to fractional precipitation with phosphotungstic acid; the crystals obtained differed widely from the analogous kyrine precipitates from casein. After isolating glutamic and similar acids from the mother liquor as hydrochlorides, cupric salts were formed and these divided into fractions by precipitation with a solution of cupric salt from gelatin which would correspond to the caseinic acid fraction of casein contained in glyco-coll. —R. L.

UNITED STATES PATENT.

Agar-agar; Process for Manufacturing Limpid Solutions of —, and Product of same. W. Riebensahn, Chemist. U.S. Pat. 784,349, March 7, 1905.

BY boiling agar-agar under pressure with a dilute aqueous

tion of an organic acid (e.g., citric acid), allowing to stand, and filtering, a limpid solution is obtained, which sets stiff jelly on cooling. The weight of organic acid used should not exceed 1.5 per cent. of the weight of agar-agar to be dissolved.—T. F. B.

FRENCH PATENTS.

ing Materials; Digestor for the Extraction of —. —, met, Spazin et Cie. Fr. Pat. 347 589, Oct. 31, 1904. Vegetable matter is charged into a large open or closed extraction vessel, and is extracted by a heated liquid which is kept in continual circulation. The liquid is drawn from the bottom of the vessel by means of a ejector, which forces it up an external pipe and returns it again at the top of the extraction vessel. The heat required for extraction is derived from a steam jet of the ejector.—J. F. B.

Method of Preparing —, for Rapid Tanning. R. Berthon. Fr. Pat. 347,315, Oct. 22, 1904.

skins previous to being tanned are immersed in a solution and subjected to the action of an alternating electric current. For strong leather, a solution of a sulphate or phosphate is used, whilst for lighter kinds of leather the electrolyte is a solution of a chloride acidulated with sulphuric acid.—A. S.

XV.—MANURES, Etc.

en Compounds; Comparative Assimilability of —. —, L. Lütz. Comptes rend., 1904, 140, 667.

author has previously shown that the assimilability of amines is inversely as their molecular weights, so such rule is discoverable in the case of amides, nitriles are hardly assimilable at all. He now finds that all nitrogen compounds, amides are the most assimilable; amines occupy the second place, nitriles the third. The simplest molecule is thus the purest of nitrogen for plants.—J. T. D.

Coating —, with Germinating Substances. A. J. Boulton, London. From A. Re. Rome. Eng. Pat. 31, Feb. 13, 1904.

are coated in a rotary pill-coating machine with a fertilising mixture, the ingredients of which may be varied according to the character of the soil in which they are to be grown. A suitable mixture for general use is composed as follows:—"Vegetable earth," 3.3; calcium carbonate, 30; potassium carbonate, 8; slag, 7; copper sulphate, 2; quick-lime, 2; a sulphate, 2.5; glue, 1; ammonium carbonate, 12.5 parts.—J. F. B.

Process and Apparatus for the Production of a new Chemical —. X. M. Roux, Paris, and B. Gonin, London. Eng. Pat. 6920, March 22, 1904.

manure, which is called "humate of calcium phosphate" is prepared by mixing humus (three parts) with a phosphate (one part), the two constituents being fed to the mixing machine by means of a funnel which is provided with a partition so as to form two compartments of the desired sizes.—N. H. J. M.

Process of and Apparatus for the Recovery of Ammonia from Gases from the Process of Manufacture. X. M. Roux, Paris, and B. Gonin, London. Eng. Pat. 6921, March 22, 1904.

gases containing ammonia are passed through a filter in which peat, which has been previously treated with an alkali, is suspended in wire baskets. The peat is

stated to absorb the ammonia and to be converted into a nitrogenised substance.—N. H. J. M.

Humus for Fertilising Purposes; Process for the Treatment of —. X. M. Roux, Paris, and B. W. Gonin, London. Eng. Pat. 6922, March 22, 1904.

THE manure, "humate of ammonia," is prepared by spraying a predetermined amount of humus, with the maximum amount of water, containing an alkali in solution, which the humus will absorb.—N. H. J. M.

FRENCH PATENT.

Calcium Orthophosphate, Mono, [Fertiliser]; Preparation of —. E. Burleigh and A. J. King. Fr. Pat. 347,307, Oct. 21, 1904.

CALCIUM phosphate, which may contain calcium carbonate, is treated with sufficient orthophosphoric acid to form monocalcium orthophosphate. The magma is dried and powdered for application as a manure. The phosphoric acid used may be obtained by treating calcium phosphate with sulphuric acid, and concentrating the solution, separated from the calcium sulphate formed.—E. S.

XVI.—SUGAR, STARCH, GUM, Etc.

Sugar in Solution; Decomposition of — by Heat. O. Molenda. Oesterr.-ungar. Z. Zuckerind., 1904, 33, 862. Bull. Assoc. Chim. Sucr. et Dist., 1905, 22, 712—714.

EXPERIMENTS with a faintly alkaline solution of pure sugar, containing only a small quantity of invert sugar, showed that there is no notable decomposition of sugar in consequence of superheating by contact with the heating surface. The loss of sugar due to decomposition is independent of the heating surface and of the temperature of the heating agent (steam), if other conditions are the same, that is, in the case of equal quantities of sugar solution at equal initial concentrations, boiled under equal vacuum to the same final concentration, the temperature of ebullition and the duration of boiling being also the same. In evaporating a definite amount of water from a sugar solution under a given vacuum, the loss of sugar decreases with the duration of boiling, or, in other words, the loss of sugar diminishes as the temperature of the steam and the area of the heating surface are increased. The colour of a sugar solution increases directly with a rise of temperature. Further experiments were made with pure and impure sugar solutions of varying alkalinity and concentration, heated for periods of 4 hours under atmospheric pressure. The results obtained indicate that under these conditions the decomposition of sugar, the decrease of alkalinity, the deepening of the colour, and the alteration of reducing power are all directly proportional to the temperature and the duration of heating. Neutral solutions rapidly become acid, and invert sugar and reducing substances are formed, the loss of sugar being greater than in alkaline solutions. The loss appears to be greater with pure than with impure neutral sugar solutions. There is no relation between the loss of sugar in saccharine solutions and the reducing power of the latter. The coloured substances formed on heating alkaline sugar solutions have practically no reducing power. The deepening of colour when sugar solutions are heated is greater in the case of alkaline than of neutral or acid solutions; it increases with the degree of alkalinity and is greater in the case of solutions made alkaline with soda or potash than in those made alkaline with lime. In general the solutions lose their alkalinity to phenolphthalein before reducing substances are formed. With regard to alkalinity in the sugar refinery, the author recommends working in such a manner that the massecuite has only a trace of alkalinity to phenolphthalein. It is preferable to use lime as alkali, especially in works where filtration is practised. In general it is best to work with a high vacuum, so that the heating is finished as quickly and at as low a temperature as is possible.—A. S.

ENGLISH PATENTS.

Sugars; Manufacture of a Crystalline —. J. F. Cross, London. Eng. Pat. 8544. April 13, 1904.

THE cellulose or hemicellulose of short cellular structure, obtained from cottonseed hulls according to Eng. Pat. 8544 of 1904 (see this J., 1905, 288), is hydrolysed with, for example, four to five times its weight of 1 to 3 per cent. sulphuric acid. The solution is filtered and neutralised with barium carbonate or chalk. After filtration, the solution is evaporated until the sugar crystallises. J. F. B.

UNITED STATES PATENTS.

Starch; Apparatus for Making —. W. H. Uhland, Leipzig-Gohlis, Germany. U.S. Pat. 784,450, March 7, 1905.

SEE Fr. Pat. 338,792 of 1903; this J., 1904, 795.—T. F. B.

FRENCH PATENTS.

Sugar Juices or Syrups; Deposition of — by means of Pure Hydrosulphites (Hyposulphites). L. Descaups. Fr. Pat. 339,253, Dec. 31, 1903.

SACCHARINE juices or syrups are treated with a regulated quantity of pure, concentrated calcium hydrosulphite (hyposulphite). The products of the reaction are precipitated by the addition of barium hydroxide or carbonate. The action of the hydrosulphite in removing the viscous constituents and coloring matters of the juice is more efficient if the treatment be performed in two successive stages at a temperature of 50°–70° C. The treated juice is then mixed with some material, such as charcoal or silica, which facilitates clarification and filtration and removes the saline matters, &c., by coagulation; it is finally filtered and passed over bone charcoal.—J. F. B.

Sugar Juices; Purification of Crude —. P. Funck. Fr. Pat. 347,238, Oct. 29, 1904.

THE crude juice is treated at a temperature of about 80° C. with 0.05–0.25 per cent. of kieselsol, the mixture is stirred for about 5 minutes, and 0.5–1.0 per cent. of lime is added. The juice is then filtered and carbonated in the usual way.—J. F. B.

Molasses; Manufacture of Feeding Stuffs from —. M. Kowalski. Fr. Pat. 347,259, Oct. 29, 1904. XVIII. A., page 341.

XVII.—BREWING, WINES, SPIRITS, Etc.

Spirit from Potatoes poor in Starch; Increased Yield of — by Addition of Kilned Malt. A. E. Schueider. Z. Spiritusind., 1905, 28, 101.

THE author has found that kilned malt may be mashed together with potatoes instead of green malt, and that the yield of spirit per fermentation tun may be increased thereby, which is particularly advantageous when the potatoes are poor in starch. The procedure followed for a fermentation tun of 3000 litres was as follows:—The water from the Henze steamers was collected in the mash-tun and cooled to 65° C., 15 lb. of kilned malt grist were then introduced with constant stirring, and after five minutes the addition of the steamed potato pulp was begun. During the addition of the potatoes the rakes were kept in motion, and kilned malt grist was added simultaneously little by little until, after half an hour, 135 lb. of malt had been used. The mash was perfectly fluid and no different in appearance from those saccharified by green malt. The time allowed for saccharification was

40 minutes, and the filtered wort showed a sacchari reading 1° Bg. higher than a similar wort saccharified by green malt.

For subsequent mashes 1 cwt. of kilned malt employed in conjunction with 50 lb. of green malt the density of the wort in this case was 0.5°–0.7° Bg. higher than with green malt alone. In addition to denser worts, it was found that the attenuation of mashes saccharified by kilned malt was 0.3° Bg. higher than those prepared with green malt alone. The average results of distillation showed an increased yield of 22 of 90 per cent. spirit per fermentation tun. The malt for the purpose is one which has been cured at a temperature of 52°–56° C.—J. F. B.

Fusel Oil; Origin of —. O. Emmerling, Berlin. 38, 953–956. (See also this J., 1904, 1107.)

THE author has continued his investigations on the fermentation of molasses by bacteria present on skins, and the production of fusel oil. It was found necessary to dilute the molasses to a concentration of 10 per cent. of sugar, since with higher concentrations the fermentation soon subsided and the formation of lactic acid ensued. In most cases the fermentation was started by potato skins, but in some cases the same fermentation was induced spontaneously by yeasts existing in the molasses. The yield of total alcohol averaged 4.3 per cent. on the molasses, or 8.9 per cent. of the sugar. The alcohols were isolated and found to contain a large proportion of ethyl alcohol and *n*-propyl alcohol, but the main constituent was *n*-butyl alcohol; amyl alcohol was practically absent. The bacteria ferment best in absence of air, but are found not to be obligatory anaerobes. In young cultures they are motile, but lose this property when spores are formed. Their dimensions are 2.5–5 μ in length and 0.6–0.8 μ in thickness. Their cell-contents are strongly granular; spores are generally formed near the middle of the cell. The bacteria liquefy gelatin slowly and ferment cane sugar solutions with evolution of carbon dioxide and hydrogen, and formation of the alcohols enumerated above, but (in presence of calcium carbonate) the chief of the sugar is converted into acids of the fatty series, chiefly butyric acid, with some acetic acid. Malt dextrose and glycerin are also fermented, but lactose is not.—J. F. B.

Flaked Cereals; Analysis of —. J. L. B. XXIII., page 353.

ENGLISH PATENTS.

Spirituous Liquids [Brandy, &c.]; Maturing of —. R. J. Friswell, London. Eng. Pat. 21,350, Oct. 29, 1904.

IMMATURE spirits are heated in an autoclave to a temperature of 212° F., for six hours, and then cooled. The treatment the quantity of esters in the spirits is increased. The temperature may be increased, but not allowed to exceed 230° F., and the time of heating correspondingly shortened. Instead of using an autoclave, the spirits may be heated under a reflux condenser.—W. P. S.

Brewers' Wash, Sewage, Waste or Spent Dyes; Evaporating and Concentrating —, the Evaporator being applicable as a Smoke Washer. A. B. Lennox. Eng. Pat. 12,145, May 28, 1904. XVIII. B., page 342.

Beer Wort from Malt Grist or Malt Flour; Clarification of —. L. Rübsam. Fr. Pat. 347,590, Oct. 31, 1904.

THE mash, prepared in any convenient manner, is maintained at the temperature of saccharification (70°–75°

ring the whole period of running off the wort. By keeping up the temperature in the clearing tun, it is contended that a finer malt grist, or even flour, can be shed without danger of clogging the filtering bed.
—J. F. B.

Fortification of Poor — by Vapours of Alcoholic Solution. E. Francon. Fr. Pat. 347,631, Nov. 3, 1904.

poor in alcohol may be fortified by distilling into the alcoholic vapours produced by boiling the washings the lees or other weakly alcoholic liquors. The washings are placed in a vertical boiler and the steam given off is condensed in a worm communicating with the reservoir of wine to be fortified. A system of recuperation is adopted by which the heat of the steam is imparted to fresh liquors for distillation.
—J. F. B.

XIII.—FOODS; SANITATION; WATER PURIFICATION, & DISINFECTANTS.

(A).—FOODS.

Beans: Natural Alkalinity of the Ash of — Froehner and H. Lührig. Z. Untersuch. Nahrungsmitt. 1905, 9, 257—263.

samples of cocoa beans examined, one sample contained 2.11 per cent. of water-soluble alkali, calculated as sodium carbonate on the dry cocoa powder, after extracting 30 per cent. of fat from the latter. The amount of alkali found, calculated to potassium carbonate, was 0.99 per cent. The author considers that a large quantity of added alkali can only be definitely to be present when the water-soluble alkali in a sample exceeds 3 per cent., calculated as potassium carbonate.—W. P. S.

Husk: Analyses of — H. Lührig. Z. Untersuch. Nahrungsmitt. u. Genussm. 1905, 9, 263—267.

results are given of determinations of the water, ash, crude fibre and alkalinity of the ash of 28 samples of cocoa husk, the investigation being made to ascertain whether any striking peculiarity could be found by means of which the detection of cocoa-husk would be rendered certain. As the percentages of crude fibre varied in 11.06 and 19.77 (average 13.05), of ash from 8.77 (average 6.46), and of alkalinity (calculated as sodium carbonate) from 0.36 to 4.80 (average 3.00), calculated on the dry substance, no reliable data for purposes were obtained. The water-soluble alkalinity of cocoa husk, being about three times that of ordinary powder, may give some indication of the presence of cocoa in chocolate, as this is usually prepared with cocoa which has not been treated with alkali.—W. P. S.

Oil: Detection of — when used as a Colouring Agent in Oils and Fats. C. A. Crampton and F. D. Sisson. XXIII., page 351.

Milk and other Food Products or Fermentable Materials: Process for Bleaching, Conditioning or Flavouring — S. Leatham, York. Eng. Pat. 5789, March 9, 1904.

flour, or other material, is subjected to the action of a current of ozonised air into which is introduced a limited supply of nitrogen peroxide. The latter destroys the disagreeable smell or flavour resulting from the use of the material alone.—W. P. S.

Flour, Flour, Milk, &c.]; Process and Apparatus for Bleaching or Sterilising — S. Leatham, York. Eng. Pat. 5790, March 9, 1904.

The first passed through an apparatus of the silent

discharge type and then through a sparking box, or it may be separately treated in an ozoniser and a sparking apparatus and the two gaseous products afterwards mixed. The mixed gases are then brought into intimate contact with the article to be treated. Apparatus similar to that described in Eng. Pat. 21,971 of 1898 (this J., 1899, 1045) may be employed for treating the air. (See also this J., 1901, 1224.)—W. P. S.

Food; Sterilisation of — W. Thorp, Limerick. Eng. Pat. 6819, March 21, 1904.

In a process for sterilising foods by means of hydrogen peroxide (see this J., 1903, 158) the patentee adds enzymes to the foods for the purpose of decomposing the peroxide, especially in the case of those articles of food which are deficient in enzymes. The latter, in the form of sterilised yeast infusion, may also be added generally to hasten the process of sterilisation.—W. P. S.

Flour: Treatment [Bleaching] of — E. Shackleton, Carlow, Ireland. Eng. Pat. 9703, April 28, 1904.

The flour is treated with nitrogen dioxide (or other oxide) produced by the electrolysis of an acid solution of sodium nitrate. The nitrogen dioxide may be mixed with air or other suitable gas. The hydrogen liberated at the cathode is separately collected and utilised for heating, &c.
—W. P. S.

UNITED STATES PATENTS.

Fatty Edible Preparation. J. E. Bloom, New York. U.S. Pat. 782,820, Feb. 21, 1905.

The preparation consists of a mixture of olein, palmitin, stearin, "trimyristine" and oleic acid in approximately the same proportions in which they exist in human fat. A "jellifying" ingredient may be added. The mixture melts at a temperature below 100° F.—W. P. S.

Oils for Edible or other Purposes [Resembling Human Fat]: Process of Preparing — J. E. Bloom, New York. U.S. Pat. 782,821, Feb. 21, 1905.

The process consists in melting fats or oils and then cooling them in order that the solid stearin and palmitin may separate from the more liquid olein. This part of the process is repeated several times. The solid and liquid portions are then analysed and re-mixed in the proportion in which they occur in human fat.—W. P. S.

Butter: Process of Refining — M. H. Greeley, Ottumwa, Iowa. U.S. Pat. 784,394, March 7, 1905.

BUTTER is melted at a temperature of 115° F. with constant stirring, then allowed to settle, and the fat separated from the water, curd, &c. The melted fat is now subjected to centrifugal action at a temperature of 90° F. and afterwards passed into a chamber, where it is thoroughly mixed with a greater quantity of pasteurised milk by means of a blast of air introduced at the bottom of the chamber, the temperature being kept at 130° F. The mixture is then withdrawn, cooled, the butter is separated, chilled for 18 hours and worked up as usual.
—W. P. S.

FRENCH PATENTS.

Molasses: Manufacture of Feeding Stuffs from — M. Kowalski. Fr. Pat. 347,259, Oct. 20, 1904.

OIL-SEED cake or other suitable fodder is mixed with molasses and the mixture is incorporated with the products of the action of dilute acids on starch. The dextrinous components act as a binding material, so that the mass may be formed into briquettes and dried. When dry, the starch products form an elastic, impervious layer over the surface, and protect the interior from the deleterious action of air and moisture.—J. F. B.

Brewers' Wash, Sewage, Waste or Spent Dye; Evaporating and Concentrating —, the Evaporator being also applicable as a Smoke Washer. A. B. Lennox. Newcastle-on-Tyne. Eng. Pat. 12,143, May 28, 1904.

THE evaporator consists of a closed cylindrical vessel in a vertical position, divided into two compartments by a perforated plate, situated near the top, through which the duct conveying the heated air or gases passes into the lower compartment. The top of the upper compartment is connected with a fan which draws off the steam and waste gases. The liquid is continuously pumped from the bottom of the lower compartment into the upper compartment, from which it flows through the perforated plate in the form of a fine shower back into the lower chamber, and during its fall comes in intimate contact with the hot gases entering the apparatus. —J. F. B.

Water and Impure Effluents; Apparatus for Mixing and Distributing Chemicals for purposes of Purification and Sterilisation of —. A. Howatson, Paris, and W. Baby, London. Eng. Pat. 28,239, Dec. 23, 1904.

THE apparatus is principally intended for use with Duyk's "Ferrochlor" process (this J., 1903, 960). Three tanks placed side by side contain respectively the water to be treated and the two chemical solutions. Tubes, having regulated orifices, and attached to floats, are provided in the chemical tanks and allow predetermined volumes of the reagents to flow from the tanks into a mixing tube. Passing down the latter, the mixture comes into contact with the water flowing down a pipe from the water-tank, the supply of water also being regulated. Reagents and water then pass through a single pipe to the bottom of a large vessel and leaving this at the top flow on to filters. The filtered water is collected in a suitable tank or the like. An alternative method of mixing the chemical solutions is claimed. The solutions flow from the tanks through tubes to the bottom of a funnel-shaped mixing vessel, and leave the latter through holes provided at the top. From these holes the mixture falls down a tube and is mixed with the water supply. —W. P. S.

SEE Fr. Pat. 338,586 of 1903; this J., 1904, 676. —T. F. B.

Water; Combined Apparatus for Producing perfectly Pure — by Distillation, Automatic and Continuous in Operation. J. S. Pearson, Glasgow. Eng. Pat. 20,984, Sept. 30, 1904.

STEAM from a boiler enters a coil in the vessel or "evaporating-tank" fig. 1, by the pipe B and the valve B, and is condensed, giving up its latent heat to the water contained therein. The hot condensed water passes by the pipe and valve C to a coil in the second vessel or "heating tank" fig. 2, where it is partially cooled, at the same time heating the water contained in the vessel. Leaving the coil in the "heating tank" by the pipe F and E, the water enters the top of the vessel fig. 2, and drops on to the perforated plate R. The "organic or volatile gases" given off, escape by the pipe G, and the condensed water, after being heated by the coil, is fed by the pipe and valves H and H' into the "evaporating tank" fig. 1, any excess

being run off by the overflow W. In the vessel fig. 1, this heated condensed water is evaporated again by the heat of the steam condensing in the coil and the vapour produced passes by the pipes I, I' to the condenser fig. 3, and when condensed flows away by the cone N and the pipe J. If desired, the steam can be mixed with carbon dioxide, oxygen or some other gas, introduced by the pipe K; the mixture condenses together and the water becomes aerated. When this is not wished for, the pipe K is cut off, and air is allowed to enter the condenser through a filter of cotton wool L, to prevent the formation of a vacuum which would hinder the free outflow of the condensed water. Cooling water enters the condenser fig. 3, at O and leaves at P, passing to a series of tanks, from which after treatment with suitable chemicals and settling, it passes through a feed-water heater to a boiler, to be converted into steam for use in the coils. Claim is not made for any special form of the different parts of the apparatus, but for the combination of apparatus; the utilisation of a coil for both condensing and cooling; the separation of the volatile impurities; the subsequent redistillation and aeration of the water; and the automatic and continuous arrangement of the combined parts. —W. H. C.

UNITED STATES PATENTS.

Liquids; Apparatus for Removing — from Solids [Melted Grease from Garbage]. C. S. Wheelwright, Bristol, R.I., Assignor to American Extractor Co., Maine, U.S.A. U.S. Pat. 783,539, Feb. 28, 1905.

A WATER-TIGHT cylinder provided with an internal carrying screw fitting its internal periphery and with perforated plates and suction-boxes, is connected with a rendering digester, so that tankage, &c., from the digester can be pressed and the water returned again and again by means of a pump and connecting pipes. A water tank is also connected with the pump and digester. —C. A.

Rendering Apparatus [for Garbage]. C. S. Wheelwright, Bristol, R.I., Assignor to American Extractor Co., Maine, U.S.A. U.S. Pat. 783,560, Feb. 28, 1905.

CLAIM is made for the combination of several digesters and water extractors (see preceding patent) with a water tank and forcing pump in common. The tank, which has a conical bottom and is capable of resisting steam pressure, is placed alongside the digesters so that its bottom is above the level of the tankage exits of the

rs; and the pump is provided with suction and
rge pipes. The grease floated off by the hot water
he garbage, &c., is received in trapped receivers,
e water can then be separated from the tankage
extractors and returned by means of the pump to
the digesters or to the hot water tank.—C. A. M.

(C.)—DISINFECTANTS.

ldehyde; *New Method of Generating — for
Fumigating Purposes.* H. V. Walker. J. Amer.
C. Soc., 1905, 27, 277—278.

ethod is based upon the addition of lime to the
is solution of formaldehyde, with the object of
ing with the water and liberating the gas. A
nt quantity of lime must be added to combine with
water and thus effect dehydration. In order to
t the lime reacting with the formaldehyde
n carbohydrates (formose, &c.), a substance, such
shuric acid or aluminium sulphate, that forms an
ole compound with the lime, is also added. For
e, the commercial 40 per cent. solution of formalde-
s mixed with about a third of its volume of com-
sulphuric acid, and eight fluid ounces of the mixture
l with 1 lb. of lime that slacks readily, for fumigating
b. ft. of space. An objection to the sulphuric
that it causes polymerisation of the formaldehyde,
ixture containing aluminium sulphate is preferable
his point of view. It is prepared by dissolving
5 lb. of commercial aluminium sulphate in 5 galls.
water, and mixing the solution with 15 galls. of
cent. formaldehyde solution. Lime in the form
se powder or small lumps is added in the same
tion as used with the sulphuric acid mixture. The
l is stated to have given excellent results in muni-
work, effecting a reduction of micro-organisms
eyanus) to the extent of over 90 per cent.—C. A. M.

FRENCH PATENT.

ection; *Process and Apparatus for —.*
Gronwald. Fr. Pat. 347,407, Oct. 25, 1904.

re destruction of vermin and of pathogenic organisms
ed apaces, e.g., the hold of a ship, an apparatus is
ed consisting of a reservoir containing a solution
maldehyde, a mixing chamber provided with
ag paddles for saturating gases with formaldehyde
; a condenser, water separator, distributing
and an aspirator. A calculated quantity of formal-
solution is introduced into the mixing chamber
it is mixed with carbon dioxide and carbonic oxide
d hot from generators. The mixed gases and
lehyde vapours are then aspirated into the space
isinfected.—J. F. B.

XIX.—PAPER, PASTEBOARD, Etc.

Size [Paper Manufacture]; *Rational Dilution*
— P. Klemm. Wochenbl. f. Papierfab., 1905,
768—770.

nits of concentration at which the solution of rosin
dded to the beater vary in practice between 15 and
s. per litre. The chief point is that the particles
rosin in the emulsion should be as minute as possible.
ering first the dilution of the rosin size by soft
it is probable that a liberation of free rosin takes
owing to dissociation as well as by the action of
rbon dioxide dissolved in the water. The fineness
emulsion depends on the conditions under which
xture of soap and water is made, the main factor
mechanical agitation. Direct dilution of size con-
tains much free rosin by a large volume of water is
omical, since the diluting water must be heated
melting point of the size and subsequently cooled
use. It is far more rational, if only crude agitating
are available, to prepare first a concentrated
n of the size and to dilute this as soon as possible

with cold water. With Erfurt's steam-atomiser the
minutest subdivision is obtained regardless of the con-
ditions and a strong size may be blown direct into cold
water. With soft water the concentration of the size
solution is of little importance, but extreme dilutions are
generally to be avoided. An alkaline reaction is essential
for the maintenance of a permanent emulsion, and since
very dilute solutions are deficient in alkalinity, the rosin
soon settles out. With hard waters the result differs greatly
according to the nature of the hardness. With waters
containing carbonate, the diluted size is rich in free rosin
and resinates of alkaline earths, but these are still held
in emulsion by the sodium carbonate produced by the
action of the hard water on the soap. With sulphate
waters, on the other hand, sodium sulphate is produced
which is devoid of emulsifying power and favours pre-
cipitation. With such waters the size should be employed
in a fairly concentrated condition, in order that a maximum
proportion of undecomposed rosin soap may remain in
the solution. Moreover, with strong solutions the effects
of fluctuations in the composition of the water are less
than when large volumes of water are used.—J. F. B.

Paper; *Sizing — with Rosin Soaps.* M. J. Griffin.
J. Amer. Chem. Soc., 1905, 27, 258—263.

A LARGE proportion of the total rosin can be removed
from sized paper by extraction with alcohol, but some
is still left as resinate until the paper has been treated
with hydrochloric acid. On the other hand, such paper
when treated with dilute hydrochloric acid and then washed
and dried, is very absorbent before removal of any of the
free rosin by alcohol. Again, experiments made by the
author have shown that it is not possible to size paper
with free rosin alone without the addition of alum or other
precipitating agent, and, in the author's opinion, this is
conclusive evidence against claims made on behalf of free
rosin sizes. He finds that alum precipitates the rosin
effectually as a resinate, and that all three constituents—
resinate, rosin and alumina—have a share in the sizing
process, the resinate being partially broken up by the
cellulose. Experiments were also made with other pre-
cipitating agents. Calcium sulphate and calcium chloride
yielded an alkaline pulp, but the paper was not properly
sized, the samples in which calcium chloride had been
used being the poorer. Some improvement was effected
by the use of an excess of sulphuric acid with the calcium
sulphate to give an acid reaction. Zinc sulphate and lead
acetate both yielded absorbent papers, and the author
thus considers that the former cannot be regarded as a
useful sizing material. He concludes that cellulose
hydrates cannot directly combine with either free rosin
acids or aluminium hydroxide to such an extent as to be
"sized," but that when aluminium resinate is beaten
into the fibres and precipitated, decomposition occurs,
and that both the rosin acids and the alumina (which is
relatively acid) enter into combination with the basic
cellulose hydrates. Finally, it is pointed out that papers
treated with hard waters or those to which calcium sulphate
has been added as a filling material cannot be effectually
sized, owing to their causing the precipitation of the size
before the addition of the alum.—C. A. M.

Sulphite-Cellulose Lyes; *Utilisation of Waste — [as
Manure].* F. B. Ahrens. Chem.-Zeits., 1905, 4,
40—41. Chem. Centr., 1905, 1, 700.

THE author has examined the method proposed by
Knoesel (this J., 1902, 489) for the utilisation of waste
sulphite-cellulose lyes. The lye was concentrated to
about 25° B., and mixed with an equal weight of Thomas
slag-meal. In no case was a rise of temperature of more
than a few degrees observed, nor was the citrate solubility
of the phosphoric acid increased. The organic constituents
of the lyes are in no way changed by the treatment with
Thomas slag-meal, except that a small proportion com-
bines with lime, and is thereby rendered insoluble, and
the method cannot therefore be considered of any value.

Bleaching Vegetable Textile Matter [Paper Pulp], Flax, Hemp, Ramie, Jute and Cotton. A. Gagedois. First Addition, dated Oct. 17, 1904, to Fr. Pat. 306,276, Dec. 15, 1900.

CLAIM is made for the application of the process of bleaching vegetable textile material described in the principal patent (see Eng. Pat. 23,110 of 1900; this J., 1902, 48), to the bleaching of paper pulp.—T. F. B.

Cellulose of Gorse and Similar Materials; Utilisation of — for Manufacturing Artificial Silk, Celluloid, Plastic Substances, Dynamite, and for other Purposes. G. P. Horteloup. Fr. Pat. 347,353, Oct. 24, 1904.

CLAIM is made for the utilisation of cellulose obtained from gorse according to Fr. Pat. 327,136 of 1902, and 331,176 of 1903 (see this J., 1903, 879 and 1145) for preparing nitrocellulose for various purposes.—T. F. B.

Plastic Material; Composition and Preparation of an Improved — from Nitrocellulose. L. L. Bethisy and Soc. M. Rose et Cie. Fr. Pat. 347,303, Oct. 21, 1904.

NITROCELLULOSE is bleached in a solution containing bleaching powder and aluminium and magnesium sulphates and is then treated in the wet condition (40—50 per cent. of moisture) with 15—20 per cent. of a mixture containing crystallised zinc chloride, 75; a solution of citric acid (50) in 90 per cent. alcohol (100), 20; aspic (spike-lavender) oil, 5 parts; and if desired, also with some colouring matter. The mass is well mixed by grinding, pressed to remove moisture, and dissolved in the following mixture:—amyl acetate, 26.7 kilos.; ether, 15 kilos.; 90 per cent. alcohol, 7.5 kilos.; glacial acetic acid, 0.8 kilo.; and a solution of calcium chloride in its own weight of 90 per cent. alcohol, 20 kilos. The pasty mass is allowed to stand for 24 hours in a closed vessel, passed between rollers heated to 60° C., till it is of the proper consistency, then covered with a solution of gelatin, albumin or protein in glacial acetic acid, again rolled, and formed into the desired objects. (See also Fr. Pat. 340,622 of 1904; this J., 1904, 825.)—A. S.

Celluloid and Nitrocellulose; Process for Rendering — Non-inflammable. W. C. Parkin. Fr. Pat. 347,446, Oct. 27, 1904.

CELLULOID or nitrocellulose compositions are mixed with boric acid either in the form of an alcoholic solution or of a dry powder, for the purpose of making the product non-inflammable. (Compare Fr. Pat. 344,501; this J., 1904, 1111.)—J. F. B.

Celluloid for Imitation Horn, Shell, Ivory, Pearl, etc; Manufacture and Application of — T. Didier. First Addition, dated Oct. 28, 1904, to Fr. Pat. 336,970, Nov. 3, 1903 (this J. 1904, 453).

The process of steeping articles in the celluloid paste (*loc. cit.*) is carried out in a closed chamber. The articles are fixed on a beam capable of being rotated on an axis. The vessel containing the pasty composition is raised by a rack and pinion until the articles are immersed. When the

steeping is finished, the vessel is lowered, the article drained, and the beam which carries them is rotated through an angle of 180°, so as to bring another set of articles to the steeping vessel. Meanwhile the first set is and the volatile solvents discharged from them recovered by condensation in a cooling worm.—J. B.

XX.—FINE CHEMICALS, ALKALOIDS ESSENCES, AND EXTRACTS.

Amyl Alcohol; Impure Commercial — H. D. Mond and J. A. Goodson. Analyst, 1905, 30, 77.

ATTENTION is drawn to the fact that amyl alcohol is to contain petroleum as an impurity, owing to the petroleum casks for packing the alcohol; the presence as much as 4 per cent. of petroleum has been recorded. The authors have examined a sample of commercial alcohol which contained about 1 per cent. of petroleum and which gave excessive results when employed for the determination of fat in milk by Gerber's method. The above proportion of petroleum is soluble in the mixture of amyl alcohol, sulphuric acid and water used in the method, but it is wholly or partially extracted from the mixture by the fat of the milk. Amyl alcohol which contains any visible insoluble layer when 2 c.c. are treated with 10 c.c. of water and 10 c.c. of sulphuric acid should be used for testing milk. The petroleum remains in residue when the amyl alcohol is distilled by fractionation to 131° C.—J. F. B.

Acetone; Action of Magnesium Amalgam on — F. Courturier and L. Meunier. Comptes rend., 1905, 140, 721—723.

WHEN dry acetone is gradually added to magnesium amalgam a violent reaction ensues, which ceases when about three molecular equivalents of acetone have been added for one atom of magnesium. The product is a greyish mass which contains finely divided mercury which is rapidly decomposed by moisture. This product, magnesium-acetone, is formed in reality by the union of two molecules of acetone with one atom of magnesium, the third molecule of acetone being acetone of crystallisation. When magnesium-acetone is decomposed and thoroughly extracted with boiling water, a copious deposit of crystals of pinacone hydrate ($(CH_3)_2C(OH)COH$) separates out. When the magnesium-acetone is subjected to dry distillation at a temperature of 250°—300° C. for 36 hours, the products of distillation consist of acetone (of crystallisation) isopropyl alcohol, pinacol (main product) and mesityl oxide.—J. F. B.

Piperazine; Glycerophosphates of — A. A. Comptes rend., 1905, 140, 727—780.

THE acid glycerophosphate of piperazine is prepared by evaporating a solution of 2 mols. of glycerophosphoric acid and 1 mol. of piperazine. It is an uncrystallisable viscous mass soluble in water in all proportions; the solution is precipitated by lead acetate, picric acid, &c., but not by barium chloride, silver nitrate and other precipitants. This body has a composition corresponding to the formula $[H_2PO_3 \cdot OC_4H_8N_2(OH)_2]_2 \cdot C_4H_{10}N_2$. It is neutral to methyl orange, but acid to phenolphthalein. In presence of the latter, it is neutralised by three equivalents of alkali, and is split up into $NaOC_4H_8N_2(OH)_2 \cdot C_4H_{10}N_2$ and sodium glycerophosphate. Piperazine glycerophosphate, $H_2PO_3 \cdot OC_4H_8N_2$, is prepared from a mixture of equimolecular proportions of glycerophosphoric acid and piperazine, preferably in alcoholic solutions, from which it separates in crystalline form, melting about 155° C. with decomposition. It is acid to phenolphthalein and alkaline to methyl orange, being neutralised by one equivalent of alkali or acid respectively.—J. F. B.

Pyridine; Action of Formaldehyde on — E. Form. Ber., 1905, 38, 944—945.

IF pyridine be heated on the water-bath for some time with an excess of 40 per cent. formaldehyde solution, then

ling, a condensation product is obtained in the form of a white crystalline paste, which finally sets to a solid. The product is regarded by the author as either a dition compound of formaldehyde and pyridine, H.CHO , or an unstable alkine, $\text{C}_5\text{H}_4\text{N}.\text{CH}_2\text{OH}$. It is easily soluble in warm, less readily in cold water. It crystallises from alcohol in rosettes of microscopic size. When heated, it is decomposed into formaldehyde and pyridine; some decomposition takes place even at ordinary temperature.—A. S.

Oil and Terpenic Compounds; Successive Redistributions of —, among the Organs of an Annual Plant. Charabot and G. Laloue. *Comptes rend.*, 1905, 1, 667–669.

ARISING from the results of all their former work, the authors come to the following conclusions:—During the period of inflorescence, an essential oil poor in estragol is present in terpenic compounds accumulates in the green parts of the plant. It is relatively soluble, for the terpenic compounds, especially those other than linalöl, are more soluble than estragol. The early flowers contain an essential oil less soluble, but richer in estragol. When the plant is mature, the amount of essential oil diminishes in the green parts and increases in the flowers; and the quantity of that in the green parts diminishes and becomes less than that of the oil in the flowers. Yet the solubility of the latter does not increase, so that the oil in the plant, as a whole, diminishes, a result of its becoming poorer in terpenic compounds. Later, when the fruit has ripened, the amount of oil in the green parts has increased, that in the inflorescence has diminished; and, while the solubility of the oil in the green parts has increased, that of the oil in the inflorescence has not diminished, that of the oil in the green parts has increased. There has been a variation both of estragol and of terpenic compounds, relatively greater in the case of the former.—J. T. D.

Pharmaceutical Product [m-Tolylsemicarbazide]; Manufacture of a New —. H. E. Newton, London. From Farbenfabr. vorm. F. Bayer and Co., Elberfeld, Germany. Eng. Pat. 7954, April 6, 1904.

THE following additional methods are claimed for preparing m-tolylsemicarbazide, as described in U.S. Pat. 844 of 1904 (this J., 1904, 950):—(1) Treating m-tolylhydrazine or its salts with urea, carbamic chloride, urethanes; (2) treating di-m-tolylcarbazide with $\text{H.NH.C}_6\text{H}_4.\text{CH}_3$, with ammonia or urea; (3) treating the esters of m-tolylhydrazine carboxylic acid, $\text{CH}_3.\text{C}_6\text{H}_4.\text{NH.NH.COOR}$, with ammonia; (4) heating to above its m. pt. (e.g., to 140°C), asymmetric m-tolylsemicarbazide, $\text{CH}_3.\text{C}_6\text{H}_4.\text{N}(\text{NH}_2).\text{CONH}_2$. The latter compound is obtained by treating benzaldehyde with m-tolylhydrazine with carbonyl chloride in pyridine solution, converting the chloride thus produced into the amide, and boiling the amide with sulphuric acid.—T. F. B.

Barbituric Acid; Manufacture of Derivatives of — [Dialkylbarbituric Acids]. C. D. Abel, London. From Act.-Ges. f. Anilinfabr., Berlin. Eng. Pat. 8513, April 13, 1904.

DIALKYLBARBITURIC acids are produced by the action of carbonyl chloride on dialkylmalonic acid diamides, $\text{R}_2\text{C}(\text{CONH}_2)_2$, at temperatures above 100°C . The excess of carbonyl chloride is distilled off on the completion of the reaction, and the product may be recrystallised from water. Dialkylmalonic acid dinitrile is obtained as a by-product in this reaction. (Compare Eng. Pat. 8302 of 1904; this J., 1905, 289.)—T. F. B.

Phenol Compounds; Manufacture of New —, and the Separation of Phenols from Phenol Mixtures. H. E. Newton, London. From Farbenfabr. vorm. F. Bayer und Co., Elberfeld, Germany. Eng. Pat. 9953, April 30, 1904.

CRYSTALLINE additive compounds of phenols with the alkali salts of phenols are obtained by treating phenols with alkali hydroxides or carbonates, or with the alkali salts of phenols, with or without the use of a suitable solvent. Thus, p-cresol yields the compound $\text{CH}_3.\text{C}_6\text{H}_4.\text{OK}.3\text{CH}_3.\text{C}_6\text{H}_4.\text{OH}$, when treated with potassium hydroxide. The compound $\text{C}_6\text{H}_5.\text{OK}.3\text{C}_6\text{H}_5.\text{OH}$ may be obtained in a similar manner from phenol. Two mols. of phenol or p-cresol form additive compounds with 1 mol. of the sodium salt of the phenol. These additive compounds are stated to possess valuable therapeutic (especially antiseptic) properties. This reaction of phenols may be utilised for the separation of phenols from each other or from other organic compounds, by the fractional solution of the additive compounds. Thus, a mixture of o- and p-cresol may be separated by heating with 13 per cent. of its weight of potassium hydroxide, filtering the crystalline mass from the cooled solution, and acidifying the filtrate, from which o-cresol separates. The crystalline mass is freed from the remainder of the o-cresol compound by washing with small quantities of benzene, and is heated with acid; p-cresol crystallises from the solution on cooling.—T. F. B.

Aldehydes $\text{R}_2\text{CH}.\text{CHO}$ and $\text{RR}^1\text{CH}.\text{CHO}$; Process for Preparing the —. A. Behal and M. Sommelet. Fr. Pat. 347,399, Jan. 6, 1904.

ALDEHYDES of the general formula $\text{RR}^1\text{CH}.\text{CHO}$ are prepared by the action of acids on the ethers of the corresponding dialkyl- or diaryl-glycols $\text{RR}^1\text{CH}(\text{OH})\text{CH}_2\text{OH}$. The simple disubstituted glycols $\text{R}_2\text{C}(\text{OH})\text{CH}_2\text{OH}$ are obtained by the action of 2 mols. of the corresponding organomagnesium halide on alkoxyl- or aryloxy-acetic esters, according to the equation:—

The mixed disubstituted glycols, on the other hand, are obtained by the action of 1 mol. of organomagnesium halide on 1 mol. of the requisite hydroxyketone ether:

Ethoxy- or methoxy-acetonitrile, for use in the first

method, is prepared by the action of mercuric cyanide, in the cold, on monochloro-methylethyl- or dimethylether. The hydroxyketone ethers are prepared by decomposing with water the reaction product of ethereal solutions of organomagnesium halides and ethoxyacetoneitrile. The new ethoxyketones obtained by this process were ethoxybutanone; ethoxy-1-methyl-5-hexanone-2; and ethoxyacetophenone. A number of new glycol derivatives, obtained as above, are described, and also the following new aldehydes: Diethylacetaldehyde, dipropylacetaldehyde, diisobutylacetaldehyde, ethylpropylacetaldehyde, diisobutylacetaldehyde, methyl-2-octanal-1, and methyl-2-nonanal-1.—T. o-Hydroxybenzoic Acid (Salicylic Acid); Process for Making the Phenol or Naphthyl Ethers of —. Act.-Ges. f. Anilinfabr. Fr. Pat. 347,734 Nov. 8, 1904.

PHENYL or naphthyl ethers of salicylic acid

may be prepared by heating the corresponding alkali phenolate or naphtholate with *o*-chlorobenzoic acid in presence of a small quantity of copper or a copper salt and excess of the free phenol. The new *p*-cresyl- and *o*-methoxyphenyl ethers of salicylic acid may be prepared by this method, and are described.—T. F. B.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Photographic Processes; Theory of —. Chemical Dynamics of Development. S. E. Sheppard and C. E. K. Mees. Proc. Roy. Soc., 1905, 74, 447—473.

It is proved experimentally that, in photographic development, the amount of silver deposited increases rapidly at first, then more slowly, and finally tends to a definite limit, which depends solely on the exposure. The velocity depends on the concentration of the developer. A soluble bromide reduces the velocity, but the retardation with time is not so great. It is shown that, if *T* be the optical transparency of the silver deposited in photographic processes, the density ($= -\log T$) of that reduced silver is proportional to its mass. The equation:—

$$\frac{1}{t} \log \frac{Dx}{Dx - D} = K,$$

introduced by Hurter and Driffield (this J., 1890, 455, 529), is shown, on mathematical grounds, to represent the reaction taking place in photographic development, and is also experimentally verified. It is considered that the velocity of development mainly depends on the rate of diffusion of the active halide. In this connection, it is found that the velocity, as measured from the above equation, is directly proportional to the concentration of the reducer, is affected by the age and condition of the plate, and is reduced by the addition of soluble bromides, but not in the proportion shown by the use of the simple chemical equation of reduction alone. The law of constant density ratios due to varying exposures is also confirmed experimentally. The development factor in the sensitometry equation is considered from the mathematical point of view.—T. F. B.

Developer Amidol. A. and L. Lumière and A. Seyewitz. Brit. J. Phot., 1905, 52, 205—206.

THE oxidation of developers composed of amidol (diaminophenol dihydrochloride) and sodium sulphite is due solely to the oxidation of the amidol by atmospheric oxygen, since the amidol is much less oxidised in presence of sulphite than in a simple aqueous solution. An increase in the quantity of sulphite present only increases

the stability of the solution up to the point when it contains 3 per cent. of sulphite; further additions of sulphite render the solution more susceptible to oxidation, increase in the concentration of the developer beyond normal strength is not advantageous, owing to the precipitation of diaminophenol, and to the rapidity with which oxidation takes place, even when air is excluded. On the other hand, the "normal" developer (as 5 grms., anhydrous sodium sulphite, 30 grms., 1 litre) will keep for a long time if stored in well-closed vessels.—T. F. B.

of using only one layer of collodion, viz., between iminoid film and the gelatin, as described in the patent (this J., 1904, 1238), a second layer is added between the gelatin film and the film of emulsion.—T. F. B.

Originals [Negatives] for Producing Designs "reactions by the Chemical [Catalytic] Action of the al; Process for the De-gradation of —. Neue Photographische Ges. Act.-Ges. Fr. Pat. 347,732, No. 8, 1901. Under Internat. Conv., Oct. 13, 1904.

RES produced by the catalytic process (see this J., 380, 963 and 1015) are frequently found to prints showing too harsh contrast, owing to the action having been too powerful. It is necessary, e.g., to treat these negatives with substances which their catalytic action. For instance, "platinum" negatives may be immersed in a solution of of thiourea or of 20 drops of a saturated aqueous of sulphur dioxide in 100 c.c. of a mixture of of alcohol with one part of water. A "man- negative may be "softened" by treatment above mentioned thiourea solution. If this "ding" or "softening" action has proceeded too if the catalytic power has been reduced too much, he strengthened again by washing.—T. F. B.

XII.—EXPLOSIVES, MATCHES, Etc.

nitrocellulose; Rate of Decomposition of — and its me- tric Determination. P. Obermüller. Berl. ksverein des Ver. deutsch. Chem., Oct. 11, 1904.

thor points out that whilst Bergmann and Junk's (this J., 1904, 953) gives excellent results mining the stability of nitrocellulose, it is too ated, and occupies too much time to be of service rolling the process of manufacture. The author's consists in heating the nitrocellulose *in vacuo* at a t temperature (140° C.), and measuring continu- y means of a mercury manometer, the pressure by the evolved gases, the latter being maintained tant volume. The rate at which the pressure s is a measure of the rate of decomposition of

FIG. 1.

FIG. 2.

the nitrocellulose. The apparatus used is shown in figs. 1 and 2. The decomposition vessel Z, a small glass tube of about 12 c.c. capacity, and having a mark at 5 c.c., is connected by means of the tube T with the manometer M, which is provided with a movable mirror-scale S, and with a side tube R, by which it is joined to the pump. A receiver is interposed between the manometer M, and the pump beyond H¹, and two taps H and H¹ are provided to cut off this receiver from the manometer or from the pump. By raising or lowering the mercury reservoir, G, the level of mercury in the left limb of the manometer can be adjusted to a predetermined mark, m, and thus a constant volume maintained. The decomposition-vessel is heated in a bath of calcium chloride solution, L, covered by a thin layer of paraffin oil, and this part of the apparatus is enclosed in a casing of sheet iron, K, provided with a window of strong glass. The nitrocellulose is pressed until it contains from 30 to 35 per cent. of moisture, and then forced through a sieve with 2 mm. mesh. About 2 grms. of the prepared sample are placed in the decomposition vessel and pressed down by means of a glass rod until it occupies a volume of 5 c.c., the glass rod is left in the vessel (see fig. 2). The apparatus is then evacuated, the tap H¹ closed, and the decomposition-vessel immersed up to a definite mark (1 cm. below the top) in the bath, which has been heated to 140° C. After about 10 minutes, the water which has condensed in the left limb of the manometer is forced into the receiver by raising the mercury reservoir, the level of mercury in this limb is then adjusted to the mark m, and the zero point of the scale is placed opposite the level of mercury in the right limb. After the decomposition vessel has been heated for 15 minutes, the tap H is also closed. (If a pump which acts continuously, e.g., a water-pump, be used, the tap H¹ is not needed.) The time is noted, and then after definite intervals, the increase of pressure is read off on the scale, the level of mercury in the left limb being adjusted before each reading. At the end of the test, the decomposition-vessel is removed from the bath, allowed to cool, cleaned and weighed. The pressures observed are reduced to the corresponding ones for 1 gm. of substance.

The following results were obtained with: (a) a sample of guncotton (12.9 per cent. of nitrogen; solubility in ether-alcohol, 8 per cent.); (b) a sample of collodion-cotton (12.4 per cent. of nitrogen; solubility in ether-alcohol, 98 per cent.).

Time. mins.	Guncotton.		Collodion Cotton.	
	Pressure. mm.	Increase of Pressure. mm.	Pressure. mm.	Increase of Pressure. mm.
0	0	19	0	15
15	19	22	15	16
30	41	25	31	20
45	66	29	51	24
60	95		75	

The results obtained by the author's method in one hour correspond well with those yielded by Bergmann and Junk's process in 7—8 hours.

As an example of the application of the method to the control of the manufacturing process, the author examined the influence of washing at the boiling temperature on gun-cotton. The results are shown in the following curve-diagram.

After the fifth washing in the boiling vessel, the stability of the product had attained the desired standard. The process of beating the gun-cotton in a hollander is next referred to, and the author states that the disintegration has a markedly favourable influence on the stability of the explosive, quite apart from its action in promoting the washing. In this connection it is pointed out that the specimen of gun-cotton which after five washings behaved satisfactorily with regard to stability, was tested after being ground; when tested in the unground condition, excessive pressure was developed in the first minute, and after a short time, the gun-cotton exploded. The relation between the state of division of the material and its stability was also clearly shown by cutting a specimen of dried, unground gun-cotton with scissors successively into smaller and smaller pieces, and testing it from time to time. It is recommended that all samples of gun-cotton before being tested, be beaten for one hour in a small hollander; and also that the technical beating process be continued, until successive test samples give constant results in the stability test.

XXIII.—ANALYTICAL CHEMISTRY.

INORGANIC QUALITATIVE.

Nitric Acid; Detection of —, by the Diphenylamine Reaction. G. Frerichs. Arch. Pharm., 1905, 2, 1.

NITRIC acid is not the only compound which gives a blue colour with diphenylamine sulphate, but it is separated from all others by first extracting with ether. The substance is shaken with about 10 c.c. of concentrated sulphuric acid and 20 c.c. of ether. After the layers are separated, a little alcohol being added if necessary to hasten this process, 2—3 c.c. of the ether solution are added to a dry filter, a little diphenylamine added and cautiously 5—10 c.c. of concentrated sulphuric acid. In the presence of nitric acid, the well-known dark blue colour is developed. If the ethereal extract is coloured, it may contain iodine, bromine or chromic acid. The colour may be readily removed by shaking with aqueous sodium sulphuric acid and then carrying out the test on a fresh quantity of the filtered ether.—F. Spx.

Yttrium and Cerium Groups; Action of some Acids on the Metals of the —. H. Behrens. Trav. chim. Pays-Bas, 1904, 23, 413—418. Chem. Centr., 1905, 1, 659.

FORMIC, glycollic, lactic, paralactic, hydroxy-lactic, hydroxyisobutyric, malic, succinic, glutaric, monoacetic, fumaric, and mesaconic acids form with the metals of the yttrium and cerium groups, characteristic salts suitable for the microchemical detection of the metals. The metals of the yttrium group form slightly soluble salts with formic and acetic acids; these salts cry out, if the aqueous solution of the formate be treated with acetic acid, or if the solution of the acetate be treated with formic acid. A double salt is also formed with yttrium lactate is dissolved in a hot aqueous solution of sodium nitrate; it separates in the form of square crystals.

Aluminium as an Antidote in Acute and Chronic Arsenicalism (and Detection of Mercury). N. S. X., page 334.

INORGANIC QUANTITATIVE.

Hydrosulphites; Analysis of Solutions of —, by the Formaline. E. Orloff. J. russ. phys.-chem. Ges., 1904, 36, 1311—1317. Chem. Centr., 1905, 1, 69.

Determination of Hydrosulphites.—The method is based on the reaction of the hydrosulphite with a solution of mercuric chloride, which forms a white precipitate of mercurous chloride.

the reduction of mercuric-potassium iodide to metallic mercury by the hydrosulphite, and determination of mercury by means of iodine.

a. of a solution of mercuric-potassium iodide (60 of mercuric chloride and 260 grms. of potassium iodide) are mixed with 10 c.c. of potassium iodide solution (500 grms. per litre), and 2 c.c. of the sulphite solution. The separated mercury is filtered on a plug of asbestos, washed with water, introduced into a solution of sodium hydroxide (100 grms. per litre), 1 c.c. of N/10 iodine solution added. The solution is acidified with hydrochloric acid, and the excess of iodine is titrated with N/10 thiosulphate solution.

Determination of Formaldehyde.—Formaldehyde reduces mercuric-potassium iodide according to the equation:

c. of the formalin solution (containing 10 c.c. of formaldehyde per litre) are treated with 10 c.c. of mercuric-potassium iodide solution, and the separated mercury filtered off and determined as described above.

—A. S.

Aluminium; Determination of Acids combined with —. O. Schmatolla. Ber., 1905, 38, 985—989.

The author investigated the influence of carbonate, contained in standard alkali solutions, on the results of the determination of acids combined with aluminium. He determined the quantity of sulphuric anhydride contained in a solution of aluminium sulphate by precipitation with barium chloride. The results of subsequent titrations of the same solution with alkali differed more or less from those obtained gravimetrically, according to whether the standard solution was prepared from chemically pure sodium hydroxide, from commercial caustic potash containing carbonate, or from sodium carbonate. Differences were also observed between the direct titration of the boiling solution and the titration in the cold after decomposition of the aluminium sulphate with barium chloride. This is due to the structure of the aluminium sulphate and to the formation of neutral salts. In the presence of the latter, it is, according to the author, impossible to precipitate pure aluminium hydroxide from a sulphate solution; the decomposition is incomplete even with an excess of alkali. This effect of the neutral salts is much stronger when caustic soda is used than with alkali carbonate, probably owing to the formation of basic alkali salts. Although the alkali carbonates are also affected in their power of reaction by the presence of neutral salts, they are preferable for the determination, as the percentage of aluminium sulphate they contain is always constant, and stated by the author to correspond to $\frac{1}{140}$ of the total amount. However, the reaction to phenolphthalein, of which 10 drops are required for about 1 gram of aluminium sulphate, is more distinct with carbonate than with caustic alkali. The author recommends as the most reliable method for the determination of acids combined with aluminium, the titration of the boiling solution of aluminium salt with alkali carbonate, till phenolphthalein turns distinctly red, subsequently titrating back with acid if necessary. To compensate for the incomplete decomposition of aluminium sulphate, the number of c.c. of standard solution used, should be increased by 0.75 per cent. Nitrates, nitrites and chlorides, the addition of an excess of sodium carbonate and back titration is always reliable on account of the volatility of the respective acids. —R. L.

Parting. W. F. Hillebrand and E. T. Allen. U.S. Geological Survey, Series E., Chem. and Physics., 41, Bull. No. 253.

The authors' experiments were made on telluride gold ores from Cripple Creek, Colo. The results, which are given in a series of tables, show that the crucible fire assay yields results quite as accurate as those obtained by the wet method, provided corrections be made for losses in cupelling and those due to retention of gold by the slag. The amount of gold retained by the slag is very small and generally negligible if a suitable charge be employed. The authors obtained the best results with the following charge:—Ore, 1 assay ton (29.166 grms.); sodium bicarbonate, 1 assay ton; litharge, 6 assay tons; fused borax, 10 grms.; with a covering of sodium chloride. The loss in cupelling is more considerable, that due to absorption by the cupel being greater than that caused by volatilisation. If the cupellation be carried out at a temperature at which "feather" litharge is abundantly formed, the loss due to volatilisation is generally negligible, or perhaps compensated for by the retention of lead by the gold bead. The loss of gold due to absorption by the cupel is very important, and increases with rise of temperature. It is greater with pure gold and alloys poor in silver than with alloys rich in silver. It is unnecessary to leave gold beads in the muffle for some time after brightening with a view to removing the last traces of lead. Experiments showed that the beads do not decrease in weight, but actually show a very slight tendency to become heavier. Silver can be completely extracted from quartation alloys by means of nitric acid, but it is necessary to repeat the treatment with acid more than twice, and to wash after each treatment. The losses of gold in parting are negligible in an ore assay.—A. S.

Cupellation and Parting in [Gold] Ore Assaying. T. Kirke Rose. J. Chem. Metall. and Mining Soc., S. Africa, 1905, 5, 165—168.

Cupellation.—The muffle shown in the illustration (see figure) has been found to give good results during the last twelve months in the Assay Laboratory at the Royal Mint, London. It is made of graphite, and there is no connection between the interior of the muffle and the space of com-

bustion, whether the fuel used be coke or gas. Air enters at the front near the top, and passes out through a hole in the back, which communicates with a tube of $1\frac{1}{2}$ in. diameter leading to the flue. This tube is of graphite inside the furnace and iron outside, and is provided with a damper for regulating the draught of air through the muffle. A good temperature for the air in the muffle is 700°C ., but if the buttons contain antimony, iron, &c., a much higher temperature must be used. The increase

Telluride Ores; Comparison of the Wet and Crucible Methods for the Assay of —, with Notes on the Ores occurring in the Operations of Fire Assay and

in the loss of gold with rise of temperature is shown by the following results:—

Charges.	Loss of Gold in Cupelling	
	at 700° C.	at 900° C.
Gold, 0.001; silver, 0.006; lead, 25 grms.	0.45	1.05
Gold, 0.001; silver, 0.010; lead, 25 grms.	0.39	0.80

A comparison of magnesia- and bone-ash-cupels showed that the most satisfactory results are obtained with bone-ash cupels of London make. The influence of various impurities in the lead buttons on the loss of gold and silver is shown in the following table. The cupellations were made at about 1000° C., and the charge consisted in each case of 1 mgrm. of gold, 1 mgrm. of silver, and 1 gm. of the impurity, with 25 grms. of lead:—

Impurity.	Loss of Gold.	Loss of Silver	Remarks.
	Per Cent.	Per Cent.	—
None	1.2	11.8	—
Tin	2.3	13.9	Slight scoria
Arsenic	3.9	16.3	Much ..
Antimony	5.3	13.2	No ..
Zinc	9.3	17.6	Much ..
Cadmium	3.5	13.1	Ring of ..
Iron	4.0	16.6	No ..
Manganese	13.6	24.3	Some ..
Molybdenum	11.0	26.2	No ..
Vanadium	7.7	21.7	No ..
Copper	10.0	32.6	No ..
Bismuth	21.8	27.9	No ..
Thallium	23.1	34.4	No ..
Tellurium	55.8	67.9	No ..
Selenium	54.1	64.5	No ..

When tellurium and selenium were present, practically the whole of the missing gold and silver were recovered by fusing the cupels. In no case was there proof of any loss by volatilisation.

Parting.—The author has found the following method to be rapid, convenient and accurate. A porcelain crucible is nearly filled with nitric acid of sp. gr. 1.25 (4 of acid : 3 of water), and the liquid heated to boiling. The watch-glass cover is then raised for a moment, and the flattened bead dropped in. Beads of the following composition have been found to give good results:—Gold, 0.1 mgrm., silver, 4—5 mgrms.; gold, 0.2, silver, 2; gold, 1; silver, 6—10; and gold, 10; silver, 40 mgrms. The large beads were parted by the boiling acid in from 5 to 10 minutes, and no second treatment with acid was required.—A. S.

Phosphoric Acid: Volumetric Determination of —.

F. Raschig. *Z. angew. Chem.*, 1905, 18, 374—376.

By using the method of filtration and washing he has described in his account of the benzidine method of sulphuric acid determination (this J., 1903, 1066), the author finds that ammonium magnesium phosphate, precipitated in the usual way, can be washed free from ammonia by a quantity of water insufficient to dissolve an appreciable amount of the precipitate, and that the latter can then be titrated by means of standard acid. A quantity of the substance is weighed for analysis, containing as nearly as possible (and not more than) 0.15 gm. of phosphoric anhydride. The solution is precipitated in a conical flask with magnesia mixture, and the precipitate collected on a 40 mm. filter prepared as described (*loc. cit.*), the filtrate being used to rinse on the latest portions of the precipitate. After the pump has completely drained off the mother-liquor, the precipitate is washed with 10 c.c. of water, then with 5 c.c. The filter is then lifted off by forceps, placed in a beaker, and the forceps and funnel rinsed with not more than 20 c.c. of water. A few drops of Methyl Orange are added, and the precipitate titrated with N/10 hydrochloric acid, shaking or stirring with a rubber-tipped rod. The change (which occurs when the reaction $\text{NH}_4\text{MgPO}_4 + 2\text{HCl} = \text{MgCl}_2 + \text{NH}_4\text{H}_2\text{PO}_4$ is com-

plete) is not very sharp, but with a little practice observed within 0.05 c.c. of N/10 acid. The result with those obtained gravimetrically.—J. T. D.

Nitrogen as Nitrites: Determination of — in —.

R. S. Weston. *J. Amer. Chem. Soc.*, 1905, 27, 281

A COMPARATIVE experimental study of the Griess-Warrington and Hlosvay methods of determining nitrogen as nitrites in water has shown that an excess of chloric acid interferes with the delicacy of the reagent but this does not apply to acetic acid. The speed of reaction varies with the amount of hydrochloric acid added, and is also affected to some extent by the reagents. The Hlosvay method is more rapid than the original Griess-Warrington method. The various modifications of the method do not yield any apparent differences in the colorations. An explanation of discrepancies obtained by different chemists with the Hlosvay method is found in the differences in mixing. If liquids be mixed, the heavier acetic acid (Hlosvay's) becomes diffused through the whole; if not, they remain at the bottom and the reaction is retarded. In the Warrington method, the variation in the alkalinity of natural waters renders the use of small additions of hydrochloric acid inaccurate. To obviate this there should be enough acid present to nullify the influence of varying alkalinity, but to add the hydrochloric acid would retard the reaction. Acetic acid, however, may be added without this drawback, and for this the author gives the preference to Hlosvay's method. On treating a decolorised sample of water with each of Hlosvay's reagents, a colour is obtained which may be compared, after standing for 10 minutes, with standard solutions treated in the same manner. It is suggested as an improvement that the solutions be made more concentrated than Hlosvay directs, to prevent excessive dilution. The following solutions are recommended (a) 8 grms. of sulphanilic acid in 100 c.c. of dilute acetic acid (sp. gr. 1.044), and (b) 8 grms. of α -naphthylamine in a litre of the acetic acid, the solutions being filtered through cotton after standing a few minutes. Two c.c. of each of these solutions are to be used in the test.—C. M.

Mercury: Determination of — in Organic Compounds [and Reactions of Mercury Succinimide].

E. R. Noll. *Arch. Pharm.*, 1905, 243, 1—5.

The volumetric determination of mercury by thionine (Ber., 35, 2015) has been adapted to the valuation of organic mercury compounds such as the drugs *Hydrarg. salicylicum* and *Hydrarg. succinimidatum*.

In order to oxidise the organic matter, 0.3 gm. of the substance is heated in a 150 c.c. flask with 4 grms. of sodium sulphate and 5 c.c. of concentrated sulphuric acid to gentle boiling until quite clear. A reflux condenser, 40—50 cm. long is provided to prevent loss of mercury by volatilisation, and this is then rinsed with 5—10 c.c. of concentrated sulphuric acid and reduced to 0.1—0.2 gm. of potassium permanganate is now added to ensure the mercury being in the mercuric condition and the heating continued until the pink colour vanishes. After cooling, the liquid is diluted to about 100 c.c., allowed to cool, 2 c.c. of 10 per cent. iron alum solution added as indicator and then titrated with N/10 thiocyanate, the flask being frequently rotated. Every 0.1 c.c. of thiocyanate corresponds to 0.010015 gm. of mercury and 93.93 per cent. of mercury salicylate was found in the drug, compared with 94.02 per cent. found gravimetrically.

The paper concludes with a description of two characteristic reactions of mercury succinimide,

When this compound is heated with zinc pyrrol is liberated, and may be detected in the usual manner by the red colour imparted to a pine shaving soaked in concentrated hydrochloric acid. Also the 10 per cent. aqueous solution added to 2 volumes of baryta-water gives a white precipitate turning greyish-black.

ag, owing to liberation of ammonia by hydrolysis subsequent formation of a mercuriamino compound. —F. Sox.

ORGANIC—QUALITATIVE.

Oil; Detection of — when used as a Colouring Material in Oils and Fats. C. A. Crampton and F. H. Sins. J. Amer. Chem. Soc., 1905, 27, 270—274.

oil is used in admixture with cotton-seed oil as a "rag" or "oleomargarine." Two commercial "rag oils" of this character, consisting of cotton-seed oil with 2 to 5 per cent. of palm oil gave the following results on analysis:—Sp. gr. at 15.5° C. 0.9119 and 0.9121; refractive index at 25° C. 1.4701 and 1.4706; density at 107.8 and 110.3; and acid value, 3.1 and 3.2. For the identification of the small amount of palm oil which would be present in the oleomargarine prepared from these products (not more than 1 per cent.), the test is placed reliance on the following reactions:—*First Method*: 100 c.c. of the fat are dissolved in 300 c.c. of amyl spirit, and the solution shaken out with 50 c.c. of 5 per cent. solution of potassium hydroxide. The aqueous layer is acidified with hydrochloric acid and extracted with 10 c.c. of carbon tetrachloride, and part of the extract treated with 2 c.c. of a reagent consisting of crystallised phenol in 2 parts of carbon tetrachloride, and then with 5 drops of hydrobromic acid (sp. gr. 1.19). The porcelain crucible is gently shaken, a bluish-green colour appears almost immediately, the absence of palm oil is indicated. *Second Method*: A solution of the reagent used in the Liebermann test for rosin oil is employed. Ten c.c. of the oil and filtered fat are shaken with an equal quantity of colourless acetic anhydride, after which one drop of sulphuric acid (sp. gr. 1.53) is added, and the mixture again shaken for a few seconds. When palm oil is present, a greenish-blue colour is seen on the lower layers, as they separate. The test was applied to various oils and fats ordinarily used for edible purposes, and all were found to give the characteristic colour. For example, sesame oil and mustard oil did give colours that could be confused with the colour yielded by palm oil, but their presence could easily be demonstrated by other characteristic tests, the sesame oil by the furfural reaction, the mustard oil by the high refractive index of the acids extracted by the alkali solution. More colouring matter in sesame oil may be revealed by repeated extraction with alcohol, and the oil will not give the blue colour in the test for palm oil. Cotton-seed oil containing 1 per cent. of palm oil reacts with the same intensity after extraction with alcohol as before. The following precautions must be observed in making these colour tests for palm oil:—(1) All reagents must be pure and colourless, any tint in the phenol, acetic anhydride or carbon tetrachloride, having an influence on the final coloration. (2) The fat under examination must be freshly and well filtered at a temperature not exceeding 70° C. (3) Exposure of the fat to air or light, or the presence of water, alcohol, ether, &c., interferes with the reaction. (4) The bluish-green colour is transient. Any colorations which occur after the lapse of several minutes must be disregarded. (5) The test should be corroborated by determining the refractive index of the fatty acids. This must not exceed 1.4615 at 25° C. in the case of oleomargarine prepared from oleo oil, cotton-seed oil and palm oil. If maize oil, mustard oil, &c., be present, this value will be much higher. Bleached palm oil does not give the reactions just described.—C. A. M.

Hydrates; Some Reactions of —. R. and O. L. Pflüger's Arch., 1905, 106, 323—328. Chem. Abstr., 1905, 1, 672—673.

Pentoses. A mixture of equal parts of glacial acetic acid and aniline is heated to boiling, and a small quantity of the substance under examination introduced, when if pentoses be present, a red colour is produced owing to formation of furfural-aniline acetate. Other aromatic amines may be used in place of aniline. With the toluidines, red furfural-toluidines, and with benzidine, brownish-red

furfural-benzidine, are formed. These compounds are all insoluble in water, but soluble in ether. *Methylpentoses* (rhamnose) react in a similar manner to pentoses, with aniline, a yellow coloration is produced. Tollens' tests for *pentoses* with orcinol and phloroglucinol can be carried out in glacial acetic acid solution if a small quantity of hydrochloric acid (one or two drops of a 36 per cent. solution) be added. *Pentoses* and *hexoses* give with orcinol a violet coloration, changing to green on addition of ferric chloride, and to red on addition of caustic soda. *Hexoses* and *hexose-forming di- and tri-saccharides* behave differently. If *dextrose* be heated with glacial acetic acid and aniline, a reddish-brown coloration is produced, changing to green on further heating. *Disaccharides* give these reactions only if they are previously hydrolysed. *o- and m-Toluidine* produce a green, *p-toluidine* a red, and benzidine a reddish-brown coloration with *dextrose*. The green colouring matter produced when hexoses are heated with aniline and glacial acetic acid is insoluble in water, but easily soluble in ether. Selivanoff's reaction with resorcinol for distinguishing *ketoses* from *aldoses* can be carried out in glacial acetic acid solution with the addition of a little hydrochloric acid. *Ketoses* give a red coloration, but not *aldoses*. Dimethylresorcinol or diresorcinol may be used instead of resorcinol; with the latter, an intense dark red to violet-black coloration is produced.—A. S.

Papers from Rags; Testing —. E. L. Sellegger. Paper and Pulp., 1905, 10, 189—191.

RECENTLY ramie fibre has been employed to a slight extent in the manufacture of German rag papers; it closely resembles linen and hemp in appearance, and is in no way inferior to these in strength and durability. The detection of ramie in admixture with rag fibres is very difficult and necessitates the examination of a section. When testing reputed rag papers for adulteration with straw- or wood-cellulose, it is usual to stain the preparation with iodine in conjunction with a reagent such as zinc chloride or calcium nitrate. In such cases, a casual examination may lead to the impression that foreign fibres are present, since fibres and particles are sometimes observed which are stained a pure blue colour by the reagent. These fragments are, however, merely the bleached residues of the "sheavy" or flax-straw, and are very numerous in canvas and coarse Russian linens. The cell elements are generally quite short, very thin, and marked with fine lines or seams; they have a slight resemblance to straw-cellulose, but the corrugated cells of the latter are absent, and the cells of the parenchyma in the "sheavy" are rarer and smaller, and of a different shape. If the calcium nitrate-iodine reagent be employed, the cells of the "sheavy" are stained a bright blue, whereas those of straw- and pine-cellulose do not acquire such a definite colour. The small proportion of "sheavy" cannot have any deleterious effect on the mechanical qualities of the paper; on the contrary, it is generally found that papers containing bleached "sheavy" are stronger than those free from the same, owing to the fact that they are prepared from coarser stronger rags.

Mercury in Mercury Compounds; Determination of — [and Reactions of Mercury Succinimide]. E. Rupp and Ph. Nöll. Inorg. Quantitat., page 350.

ORGANIC—QUANTITATIVE.

Amino Bases; Separation of Primary and Secondary —. O. Hinsberg and J. Kessler. Ber., 1905, 38, 906—911.

Separation of Primary Bases with less than Seven Atoms of Carbon from Secondary Bases. — The mixture of bases is treated with 4 mol. equivalents of potassium hydroxide in the form of a 12 per cent. solution, 1½ mol. equivalents of benzene-sulphochloride are added in small portions with agitation, and the mixture is warmed to remove excess of the sulphochloride. The liquid is acidified with hydrochloric acid, and the

precipitated benzene-sulphamides are filtered off, or extracted with ether. Any dibenzene-sulphamides present are converted into the mono-compounds by heating the precipitate for 15 minutes under a reflux condenser with sodium ethylate (about 0.8 gm. of sodium in 20 c.c. of 96 per cent. alcohol for each gm. of bases). The liquid is then diluted with water, the alcohol distilled off, and the benzene-sulphamides of the secondary bases, which are insoluble in alkali filtered off. The filtrate is acidified and the separated benzene-sulphamides of the primary bases removed by filtration or extraction with ether. The free bases are obtained from the benzene-sulphamides by heating with hydrochloric or sulphuric acid to 120—150° C. in the usual manner.

Separation of Primary Aliphatic and Hydrocarbon Bases with more than Six Atoms of Carbon from Secondary Bases.—After the treatment with sodium ethylate as described above, the liquid is diluted with water, the alcohol distilled off, the residue acidified, and the mixture of sulphamides filtered off. After drying, the precipitate is dissolved in anhydrous ether, metallic sodium added in small pieces, and the whole gently warmed on the water-bath for six to eight hours. After cooling, the ethered solution is filtered, the residue in the flask shaken with ether, and the latter poured through the same filter. The insoluble matter when acidified with hydrochloric acid yields the benzene-sulphamides of the primary bases, whilst the evaporation residue of the etheral solution contains those of the secondary bases.—A. S.

Oils, Lubricating; Testing the Behaviour of — in the Cold. R. Hackel. Mitt. Kaiserl. Königl. Techn. Gewerbe-Museum in Wien. 1905, 15, 38—43.

Is the author's opinion the best method of determining the solidification point of lubricating oils is to keep them for at least an hour immersed successively in freezing mixtures of ice and water, containing the following salts in solution:—

To Produce a Temperature of Approximately:	Salt.	Parts by Weight in 100 Parts of Water.
— 1° C.	Potassium nitrate	13.0
— 3	Potassium nitrate and sodium chloride	13.0 and 3.3
— 5	Barium chloride	35.8
— 9	Potassium chloride	22.5
— 10	Ammonium chloride	25.0
— 15	Sodium nitrate	50.0
— 18	Sodium chloride	33.0
— 21		

The salt solutions and ice must be placed in a vessel of at least 100 mm. in diameter, since otherwise the layer of liquid between the test-tube and wall of the vessel solidifies too rapidly. The results thus obtained differed very greatly from the solidification points determined by the more rapid method of immersing the tube of oil in a mixture of ice and salt. The error in the latter method is shown to differ in amount in each individual case, so that it is impossible to determine any factor of correction, and the author considers that the results cannot be regarded of value as even approximate determinations. The apparatus shown in the figure, however, is recommended as giving results closer to the truth, since it allows the oil to be cooled much more slowly. The vessel A is filled with the mixture of ice and salt, whilst none is placed in the inner chamber B, and the observation slit C. The test-tube, *n* (diameter 20 mm.) is filled with the oil to a depth of 30 mm. and closed by the india-rubber cork, *s*, through which is passed the thermometer, *t*. The tube is then placed in a larger tube, *m* (diameter 30 mm.), and kept in position by means of the cork ring, *v*, so that it is surrounded by a layer of air of about 4 mm. The tube *m* is then lowered into the vessel, B, and clamped in position. The behaviour of the oil can be observed through the slit, C, and the tubes can be raised and shaken without coming in contact with the hand. The results thus obtained with three different oils differed by

at most —1.5° C. from those given by the method of immersion in the different salt solutions, which were taken as standards of comparison.—C. A. M.

Maltose in Presence of Dextrose; Detection and Determination of Small Quantities of —. J. L. Baker and W. D. Dick. Analyst. 1905, 30, 79—83.

THE authors have critically examined the method proposed by Grimbert (this J., 1903, 382) for the detection of maltose in presence of dextrose, based on the different solubilities of their osazones in acetone. They found that benzene is not a suitable solvent for removing the by-products of the osazone reaction, since it dissolves the maltosazone. The mixed osazones, however, purified by treatment with a little cold 5 per cent. acetone; when the mixture is subsequently extracted in a Gooch crucible with 10—15 c.c. of cold 20 per cent. acetone, the filtrate deposits crystals of maltosazone mixed with a little dextrosazone. In this manner the presence of maltose can be detected with certainty provided the proportion of this sugar is not less than 15 per cent. in the mixture. The method, however, cannot serve for the quantitative determination of maltose in presence of dextrose.

Small quantities of maltose can be determined in the presence of dextrose, with a fair degree of accuracy, by determining the reducing power of the solution before and after inversion. The inversion is best effected by heating 10 c.c. of a 2 per cent. solution of the sugars with 1 c.c. of strong hydrochloric acid and 10 c.c. of water in a boiling water-bath for 90 minutes. The results so obtained may be confirmed by fermenting the solution of the sugars by *S. Marxianus*, which removes most of the dextrose, and leaves the maltose unchanged. A fall in the specific rotation and a fall in the reducing power as the result of the fermentation, is additional evidence of the presence of maltose. Finally the fermented solution may be tested by the osazone method.

above tests cannot be applied in presence of dex-
and the latter, if present, must first be removed by
and precipitations with alcohol or mixtures of alcohol
etone.—J. F. B.

Flaked Cereals; Analysis of ——. J. L. Baker.
Brewers J., 1905, 41, 186.

Brewers' extract in flaked cereals is usually deter-
by mashing a mixture of two-thirds of malt, the
f extract in which is known, and one-third of the
ed cereal. The total extract of the mixture is
d from the density of the wort, and the proportion
by the "flakes" is calculated by subtracting that
the malt. The author uses a mixture of equal parts
and "flakes," in order to decrease the error of the
t determination, passing both malt and cereal
a a Sieck mill set at 25. It is shown, however,
no yield of extract obtained from the "flakes"
largely according to the diastatic power of the
and that with the more highly cured malts, the
n of the proportion of "flakes" to malt is of con-
siderable importance. The following results are quoted
sample of flaked maize:—

Power Malt. tner.)	Extract per 336 lb. of Maize, Mashed in Proportion of 1:1.	Extract per 336 lb. of Maize, Mashed in Proportion of 1:2.
40	106.50 lb.	106.4 lb.
34	102.40 "	103.2 "
25	100.25 "	103.3 "
12	97.64 "	99.17 "

—J. F. B.

Acid; Purification and Determination of ——.
E. Rapp. Arch. Pharm., 1905, 243, 69—73.

Formic acid prepared from sodium formate,
is now made in large quantities by the action of
monoxide on powdered caustic soda under pressure,
to contain traces of sulphur and chlorine. It may
ified by shaking with litharge for 24 hours and
ling, and then precipitating the sulphur by dilution,
being insoluble in 25 per cent. acid.

The determination of formic acid or formates, oxida-
th sodium hypobromite is recommended. Carbon
and water are produced. A measured volume of
d hypobromite solution is diluted to 70—100 c.c.
oppered flask and the formic acid added in such
y that about half the hypobromite remains in
Dilute hydrochloric acid is dropped in from a
until the yellow colour of bromine becomes per-
The solution is then allowed to stand for 30
s in the dark, after which about 1 gm. of potassium
nd 10—20 c.c. of dilute hydrochloric acid are added,
e liberated iodine titrated with N/10 thiosulphate
n. The difference between the initial and final
values gives the amount of hypobromite used.
of N/10 thiosulphate corresponds to 0.0023 gm.
ic acid.

The hypobromite solution is made by dissolving 15
of sodium hydroxide (pure by alcohol) in 450 c.c.
er and adding 5 c.c. of bromine, after cooling, and
up to 500 c.c. In absence of air and light the
factor remains very constant.—F. SDN.

Hydroxylamine; Volumetric Determination of ——.
J. Simon. Comptes rend., 1905, 140, 724—727.

According to the author's method (this J., 1903, 113),
ylamine is determined by adding an excess of
xalate to a neutralised solution of the hydroxyl-
salt and titrating with permanganate. The theo-
proportion of oxalate required to give correct
according to the equation (*loc. cit.*) is 1 mol. of
m oxalate to 2 mols. of hydroxylamine. If the
tion of sodium oxalate be lower than the above,
hole of the oxalate behaves as hydroxylamine
e, and reduces the permanganate in accordance
the equation, but the excess of other hydroxylamine
duces it in another ratio (*loc. cit.*), and the results
o high. On the other hand, an excess of sodium

oxalate beyond the theoretical quantity introduce
error in the results, which may be as much as 3 per cent.
too low. The best way is to make a first titration in
presence of an excess of sodium oxalate, thus obtaining
a permanganate value slightly too low, and then to make
a second titration in presence of a volume of N/10 sodium
oxalate solution equal to double the volume of N/10
permanganate consumed in the first test. The second
titration, being made with a deficiency of sodium oxalate
proportional to the error of the first test, will give a per-
manganate value correspondingly too high. The mean of
the two tests may then be taken as the closest approxi-
mation to the true value that the method is capable of
affording.—J. F. B.

*Hydroxylamine; Action of Potassium Permanganate on
Salts of* ——. L. J. Simon. Comptes rend., 1905,
140, 659—661.

THE reaction of potassium permanganate on hydroxyl-
amine nitrate is expressed by the equation—

so that 1 molecule of hydroxylamine nitrate reduces
0.4 molecule of permanganate (as with the chloride and
sulphate, this J., 1903, 113). If the solution be now
acidified, further permanganate can be decolorised, corres-
ponding to the nitrite formed—0.16 molecule for each
molecule of hydroxylamine. This is double the corres-
ponding quantity in the case of chloride or sulphate.
With phosphate or arsenate of hydroxylamine the equation
is—

and the proportion of permanganate to hydroxylamine is
the same as in the case of the oxalate (*loc. cit.*). The
additional amount of permanganate decolorised on
acidifying is only 0.0166 molecule per molecule of
hydroxylamine.

If the hydroxylamine solution be acidified before adding
the permanganate, the reaction is much more complex
and less regular. The reducing power is increased, but
the amount of permanganate destroyed depends on the
concentration, the temperature, the rapidity of the opera-
tion, and other circumstances; so that the reaction of
permanganate in acid solution cannot be used as a mode
of determining hydroxylamine.—J. T. D.

Iodoform; Determination of ——. Utz. Pharm. Centr.,
1904, 45, 985—987. Pharm. J., 1905, 74, 405.

0.1 GRM. of the sample is dissolved in 10 c.c. of a mixture
of ether and methyl alcohol, and the solution is treated
with a few drops of fuming nitric acid and 10 c.c. of N/10
silver nitrate solution, and heated gently on the water-
bath, until an odour of ether or of nitrous acid can no
longer be detected. The solution is then diluted with
50—100 c.c. of water, and the excess of silver nitrate
titrated with ammonium thiocyanate solution. 1 c.c. of
N/10 silver nitrate solution is equivalent to 0.0131 gm.
of iodoform. In the case of bandages, &c., 5 grms. of
the material are extracted with 100 c.c. of a mixture of
ether and methyl alcohol, and the amount of iodoform in
20 c.c. of the solution determined.—A. S.

Hydrosulphites; Analysis of Solutions of —, and of
Formaline. E. Orloff. Inorg. Quantitat., page 348.

XXIV.—SCIENTIFIC & TECHNICAL NOTES.

Radium Bromide; Action of —, upon the Electric
Resistance of Metals. B. Sabat. Comptes rend.,
1905, 140, 644—646.

METALLIC wires were wrapped round a glass tube, in the
centre of which a tube of pure radium bromide could be
placed, and the electric resistance was measured before
and after the introduction of the radium bromide. The
metals used were iron, steel, copper, platinum, bismuth,

Exposure to radium bromide increased their resistance. Immediately on exposure the resistance rose suddenly, then a further gradual increase occurred, till a maximum was reached. On removing the radium, the resistance slowly fell till the initial value was regained. The variation of resistance was several times too great to be accounted for by the direct communication of heat from the radium to the wire. The author concludes that the metals, absorbing the β -radiation, transform part of its energy into heat, which raises the temperature of the metal and thus increases its resistance. The β -rays thus behave exactly like cathode rays, though with a less intensity, for they are not so readily absorbed as cathode rays.

— J. T. D.

Hydrogen and Chlorine; Cause of the Period of Chemical Induction in the Union of —. D. L. Chapman and C. H. Burgess. *Proc. Roy. Soc.*, 1905, **74**, 400.

THE retardation of the interaction of hydrogen and chlorine which is observed under certain conditions does not depend on any condition of the hydrogen. Water and aqueous solutions of salts are found to render active chlorine inactive towards hydrogen. On long contact with chlorine in presence of light, or on boiling with chlorine, the solutions lose this property, and do not regain it even on subsequent removal of the chlorine; the only method found to restore to these solutions their power of rendering chlorine inactive was the introduction of substances which react with chlorine; ammonia is the most efficient in this respect; sulphur dioxide acts similarly, but is more easily removed on exposure to light. It was proved that no decay of activity took place when an active mixture of hydrogen and chlorine was kept for some time in the dark. It is conclusively established that the phenomenon in question is due solely to the presence in the gas of substances capable of reacting with chlorine, and not to the formation of an unstable intermediate compound.—T. F. B.

Calcium; Some Applications of Metallic —.
E. Beckmann. *Ber.* 1905, **38**, 904–906.

THE metallic calcium used by the author was in the form of turnings, which keep bright in dry air. Calcium reduces nitrobenzene in alkaline, alcoholic solution to azoxybenzene, in hydrochloric acid solution further to aniline. Oximes yielded amines in alkaline as well as acid solution. Benzenesulphonichloride in alkaline solution was reduced to the sulphinic acid, in acid solution to thiophenol. In alkaline solution some mercury bichloride was always added. Calcium may replace magnesium in Grignard's reaction. The author obtained by heating iodobenzene dissolved in dry ether with finely-divided calcium after one hour, a light brown powder which yielded benzoic acid by passing carbon dioxide into the solution, or diphenyl carbinol by addition of benzaldehyde. Ethyl iodide reacts more readily, yielding calcium-ethyl iodide. The presence of ether is necessary for this reaction, for calcium remains unattacked by ethyl halide in benzene solution. According to Baeyer (see this J., 1902, 607) a combination of calcium ethyl iodide with ether to

is suggested. This would explain why ether adheres so tenaciously to these compounds, and is only split off under reduced pressure at 40° C. By addition of water, ethane is liberated and the smell of ether is perceptible. Several metallic oxides and sulphides are reduced by finely-divided calcium according to Goldschmidt's method (see this J., 1898, 543), e.g., manganese peroxide, cupric oxide, lead oxide and cupric sulphide.—R. L.

Fermentative Oxidations; Indirect —. Oxidation of Hydroquinone. L. Marchadier. *J. Pharm. Chim.*, 1905, **21**, 299–302.

UNDER the action of the oxygen of the air or of hydrogen peroxide, hydroquinone undergoes a slight oxidation, but an oxidising enzyme causes vigorous oxidation, quinhydrone and quinone being formed. When the

oxydase acts on hydroquinone in conjunction with gen peroxide, the different stages of the oxidation more clearly manifested, quinone and ordinary hydrone being obtained, together with another hydrone corresponding with a lesser degree of oxidation than the ordinary quinhydrone.—T. H. P.

Nitrifying Ferment; Influence of Ammonium Salt. Nitrication of Sodium Nitrite by the —. E. J. langer and L. Massol. *Comptes rend.*, 1905, **687**–689.

THE mineral nutrient medium employed by Winogradsky and Omeliansky for the cultivation of the nitrifying organism contains one gram of sodium carbonate per litre. The present authors find that this proportion may be reduced to 0.2 gram per litre without interfering with the nitrifying activity of the organism. With media in which the amount of sodium carbonate does not exceed 0.25 gram per litre, the addition of ammonium sulphate (1 gram per litre) in no way retards the oxidation of sodium nitrite by the ferment. Consequently, the inhibitive action of ammonium salts on the activity of the organism, reported by Winogradsky and Omeliansky, is to be ascribed not to the action of those salts themselves, but to the production of free ammonia in quantities sufficient to injure the organism, owing to the excessive proportion of sodium carbonate present in the medium and to the dissociation of the ammonium carbonate present thereby.—J. F. B.

Nicotine; Antidote to —. C. Zalackas. *Comptes rend.*, 1905, **140**, 741–742.

THE juice of *Nasturtium officinale* is a definite antidote to nicotine poisoning. This juice is very rich in iodine, especially when the plant is grown near sea coasts, and these elements, and the action of the antidote, are ascribed to the revivification of the blood corpuscles by these constituents.—J. F. B.

New Books.

MINERAL RESOURCES OF THE UNITED STATES. Year 1903. (Department of the Interior, United States Geological Survey, Chas. D. Walcott, Director.) DAVID T. DAY, Chief of Division of Mining and Geographical Resources. Washington, U.S.A., Government Printing Office, 1904.

Two volumes, containing "Letter of Transmittal," Preface, and 1178 pages of subject matter with a detailed alphabetical index of subjects. The following are the principal subjects which geographical and industrial details are given: I. Iron Ores. (i) Statistics of the American Iron Trade. II. Manganese Ore. III. Gold and Silver. IV. Copper. V. Lead. VI. Zinc. VII. Aluminium. VIII. Mercury. IX. Steel-hardening (Manganese, Nickel and Cobalt, Chromium, Titanium, Molybdenum, Vanadium, Uranium and Titanium). X. Platinum. XI. Lithium. XII. Antimony. XIII. Tin. XIV. Coal and Coke. XV. Gas. XVI. Tar, and Ammonia at Gas Works, and in Retorts. XVII. Petroleum. XVIII. Natural Gas. XIX. Asphaltum and Bituminous Rock. XX. Stone. XXI. Clay Working Industries. XXII. Cement. XXIII. Precious Stones. XXIV. Tale and Soapstone. XXV. Abrasive Materials. XXVI. Borax. XXVII. Feldspar and Cryolite. XXVIII. Gypsum and Gypsum Plaster. XXIX. Phosphate Rock. XXX. Salt. XXXI. Pyrites. XXXII. Barytes. XXXIII. Paints. XXXIV. Asbestos. XXXV. Flint and XXXVI. Graphite. XXXVII. Magnesite. XXXVIII. Mineral Waters. XXXIX. Monazite and Zircon. XL. Glass Sand.

Trade Report.

I.—GENERAL.

CAPE COLONY; TRADE OF — IN 1904.

Bd. of Trade J., March 16, 1905.

Following tables show the total value of the imports and exports, including transit trade in both cases, of articles into and from Cape Colony during 1903 and 1904.

Imports into Cape Colony.

Article.	Year ended 31st December, 1903.	Year ended 31st December, 1904.
Gold metal manufactures	£ 3,863,000	£ 2,510,000
Gold leather manufactures	1,491,000	877,000
Beverages	580,000	385,000
Chemicals	365,000	246,000
Candles	231,000	242,000
Coal and patent fuel	295,000	204,000
Rail	136,000	165,000
Ammunition (includes te and blasting com- and powder)	216,000	156,000
Are manufactures	196,000	123,000
Colours (includes ine and varnish)	159,000	100,000
Stores	85,000	73,000

1.—The figures of imports into Cape Colony are exclusive of supplies by the Imperial Government, but supplies for the stores still partly contracted for on the spot.

Exports from Cape Colony.

Article.	Year ended 31st December, 1903.	Year ended 31st December, 1904.
Wool	£ 457,000	£ 514,000
Skins	469,000	476,000

TRANSVAAL; TRADE OF THE — IN 1904.

Bd. of Trade J., March 16, 1905.

Following tables, showing the value of certain articles imported into and exported from the Transvaal for the year ended 31st December, 1904, as compared with the year 1903, have been compiled from official figures published in the *Transvaal Government Gazette* of February 1905.

Imports.

Article.	1903.	1904.
Gold manufactures	£ 3,769,000	£ 2,550,000
Chemicals	500,000	472,000
Gold and manufactures	735,000	468,000
(includes ale, spirits, and mineral waters)	814,000	426,000
Ammunition (includes te and other explosives)	130,000	291,000
And oilmen's stores	398,000	289,000
As oils and paints)	246,000	239,000
Candles	113,000	74,000
Glassware	80,000	42,000
Ware and crockery	41,000	41,000
And lime	35,000	30,000
Coal and patent fuel	9,000	23,000
Phosphoric material	34,000	21,000

Exports.

Article.	1903.	1904.
Coal	£ 151,000	£ 144,000
Skins, hides and horns	4,000	40,000

II.—FUEL, GAS, AND LIGHT.

MANTLES FOR INCANDESCENT LIGHT; TARIFF CLASSIFICATION OF — IN RUSSIA.

Bd. of Trade J., March 23, 1905.

The Russian Customs Department have notified that annealed mantles for incandescent light are to be dutiable on importation into Russia under Article 169 of the tariff as "physical apparatus for intensifying light," at the rate of 10 rubls. 20 cop. per pound (7½d. per lb.).

Similar mantles, not annealed, of textile materials, even if impregnated with a mineral substance, are to pay duty according to the material of which they are made.

III.—TAR PRODUCTS, PETROLEUM, Etc.

PARAFFIN: U.S. CUSTOMS DECISION.

The United States Circuit Court has decided that both liquid paraffin and paraffinum molle, a product of petroleum and a wax, are free of duty as "paraffin" under paragraph 633 of the free list. The ground taken by the Court was that the enumeration of paraffin by name constitutes a more specific designation than the provisions of paragraph 626, which places a countervailing duty on products of petroleum.—R. W. M.

VII.—ACIDS, ALKALIS, Etc.

ACETIC ACID; EXEMPTION FROM DUTY OF — IN THE NETHERLANDS.

Bd. of Trade J., March 23, 1905.

A Dutch Decree, dated December 23rd, 1904, exempts from taxation acetic acid and acetyl oxide (acetic anhydride) for use in the preparation of chemical products.

PHOSPHORIC ACID: U.S. CUSTOMS DECISION.

The United States Circuit Court has decided that syrupy phosphoric acid is free of duty as "phosphoric acid" under paragraph 464 of the free list. The assessment of duty as "syrup of phosphoric acid" at 25 per cent. *ad valorem* under paragraph 68, providing for "medicinal preparations," was overruled. The Treasury Department will not appeal from this decision.—R. W. M.

STRONTIUM CARBONATE: U.S. CUSTOMS DECISION.

Feb. 28, 1904.

Precipitated strontium carbonate was held to be dutiable at 25 per cent. *ad valorem* as a "chemical salt," under paragraph three of the tariff. No evidence was offered to show that it was mineral carbonate of strontia.

—R. W. M.

IX.—BUILDING MATERIALS, Etc.

CEMENT INDUSTRY; ESTABLISHMENT OF — IN CANADA.

Bd. of Trade J., March 23, 1905.

The *Monetary Times* (Toronto) states that arrangements have been completed for the building at Sydney,

Cape Breton, of a large plant for making cement from slag, one of the by-products of the Dominion Iron and Steel Company. The plant is to cost about 250,000 dol., and will be the only one of the kind in Canada. The site has been selected close to the steel works. Its capacity will probably be 500 barrels a day, and a coeprage with a capacity of 50,000 barrels a year is also proposed to be built. The plant, which is to be of steel, will probably be finished in July. The city council of Sydney have granted the company a bonus of 10,000 dol., exemption from taxes for 20 years, and low water rates, providing the company manufacture not less than 25,000 barrels of cement a year.

X.—METALLURGY.

TRANSVAAL: MINERAL PRODUCTION OF —, IN 1903-04.

Bd. of Trade J., March 2, 1905.

The following table shows the quantity and value of the mineral production of the Transvaal during the year ended June 30, 1904, with comparative figures for the preceding year:—

		1902-03.		1903-04.	
		Quantity.	Value.	Quantity.	Value.
Gold	fine ozs.	2,372,076	£ 10,075,928	3,475,911	£ 14,762,110
Silver	"	280,997	29,215	406,677	45,110
Diamonds	carats	33,572.57	46,358	487,917.14	685,729
Coal	tons	1,969,089	782,906*	2,370,465	895,910

* Value of coal sold.

The following figures show the value of the output of the various industrial concerns in the Transvaal during the year ended June last, with comparisons for the preceding year:—

	1902-03.	1903-04.
Machine-made bricks (building)	£ 59,741	£ 114,698
" " " (fire)	7,961	8,726
Cement	9,880	21,355
Lime (blue)	41,129	16,628
" (white)	12,727	56,486
Slate	6,000	15,500

PIG IRON PRODUCTION OF CANADA.

Eng. and Mining J., March 9, 1905.

The statistics of the production of all kinds of pig iron in Canada in the calendar year 1904 show an increase of 5524 gross tons, or a little over 2 per cent., as compared with 1903, but a decrease of 48,615 tons as compared with 1902.

The total production in 1904 amounted to 270,942 gross tons, against 265,418 tons in 1903. In the first half of 1904 the production was 129,643 tons, and in the second half it was 150,299 tons. Of the total production in 1904, 251,671 tons were made with coke and 19,271 tons with charcoal. About one-fourth of the total production was basic pig iron, namely, 70,133 tons. The production of bessemer pig iron, all made in the last half of the year, was 26,016 tons. Spiegeleisen and ferromanganese have not been made since 1899.

The unsold stocks of pig iron in Canada at the close of 1904 amounted to 35,119 tons. On December 31, 1904, Canada had 15 completed blast furnaces, of which eight were in blast and seven were idle. Of this total, 19 were equipped to use coke for fuel and five to use charcoal. In addition, three coke furnaces were partly erected on

December 31, but work on the furnaces had been suspended some time ago.

OPEN-HEARTH STEEL PRODUCTION OF THE U.S.

Eng. and Mining J., March 16, 1905.

The total production of open-hearth steel ingots and castings in the United States in 1904 was 5,907,666 tons, against 5,829,911 tons in 1903, an increase of 1.3 per cent. In 1902 the total production was 5,687,729 tons, in 1901 it was 4,656,309 tons. The open-hearth made in 1904 was produced by 115 works. In 1903 there were 111 such works.

The production of open-hearth steel ingots in 1904, excluding castings, amounted to 5,605,332 gross tons, against 5,429,563 tons in 1903, an increase of 175,769 tons.

In 1903, 4,734,913 tons of open-hearth steel were made by the basic process and 1,094,998 tons were made by the acid process, while in 1904 the production by the basic process amounted to 5,106,367 tons and by the acid process to 801,299 tons.

There was a decrease in the production of acid steel in 1904, as compared with 1903, of 293,699 tons, or

26.8 per cent., but an increase in the production of basic steel of 371,454 tons, or over 7.8 per cent.

The total production of open-hearth steel castings in 1904, included above, amounted to 302,334 gross tons, of which 98,919 tons were made by the basic process and 203,415 tons were made by the acid process. In 1903 the production of open-hearth steel castings amounted to 400,348 tons, of which 134,879 tons were made by the basic process and 265,469 tons by the acid process.

The total production of steel is given in the table in long tons:—

	1903.	1904.
Bessemer	Tons. 8,592,820	Tons. 7,859,110
Open-hearth	5,829,911	5,907,666
Crucible, &c.	112,238	110,000
Totals	14,534,978	13,876,776

The net result shown in this statement is that, in 1904, the production of open-hearth steel decreased 8.5 per cent., the production of basic steel decreased 2.0 per cent., the open-hearth steel castings increased 1.3 per cent. The reduction in the total production was 4.5 per cent. This decrease is somewhat in proportion to that in pig iron. The ratio of steel to pig iron, which was 80.7 in 1903, was 84.1 last year.

TIN EXPORTS FROM THE FEDERATED MALAY STATES IN 1904.

Bd. of Trade J., March 16, 1905.

The following statement, showing the weight of tin ore (tin exported in the form of ore having been refined at 68 per cent.* of the gross weight of the ore) exported from the Federated Malay States during the year with corresponding figures for the preceding years taken from the *Selangor Government Gazette* of the 3rd February:—

	1903.			1904.		
	Tin.	Tin exported in the form of Ore.	Total.	Tin.	Tin exported in the form of Ore.	Total.

(a) Quantity or value of product marketed. The ton used is that of 2,000 lb.
(b) Copper contents of ore, matte, &c., at 12·823 c. per lb.
(c) Lead contents of ores, &c., at 4·309 c. per lb.
(d) Nickel contents of ore, matte, &c., at 40 c. per lb.
(e) Silver contents of ore at 57·221 c. per oz.
(f) Oven coke, all the production of Nova Scotia, British Columbia and the North-west Territories.
(g) Gross return from sale of gas.
(h) Includes crude oil sold to refiners and oil sold for fuel and other purposes.
(i) Zinc contents of ores at 5·100 c. per lb.

The total value for 19 years, since these returns were first compiled, has been as follows:—

	Dols.		Dols.
1886.....	10,221,255	1896.....	22,584,513
1887.....	11,321,331	1897.....	28,661,430
1888.....	12,518,894	1898.....	38,697,027
1889.....	14,013,113	1899.....	49,584,027
1890.....	16,763,353	1900.....	64,618,268
1891.....	18,976,616	1901.....	66,339,158
1892.....	18,623,417	1902.....	63,885,999
1893.....	20,035,082	1903.....	62,600,434
1894.....	19,931,155	1904.....	60,343,165
1895.....	20,648,964		

The falling off of about 2,250,000 dols. in the total is mainly due to a decrease in production of gold at the richer and easily accessible portions of the Yukon placers.

The figures given account for all but 6·6 per cent. of the whole. They omit all those contributing less than 1 per cent., although some of these, such as mica and corundum, are otherwise interesting and important.

The discovery of certain cobalt, nickel, arsenic and silver ores which was announced in November, 1903, promises to add, in the near future, largely to the production of these metals. The deposits were found during the building of the Timiskaming and Northern Ontario Railway, the roadbed running almost over the top of the first of the outcrops discovered. The ores are contained in a series of almost vertical veins varying in width from 8 in. up to 6 ft., although the wider portions always contain more or less rocky matter. The veins intersect the conglomerate and slate usually classified as Huronian. All of the deposits thus far discovered possess certain features in common. The minerals represented are chiefly smaltite, niccolite and native silver, with smaller quantities of erythrite, dyscrasite, chloanthite and tetrahedrite. In some the native silver is very abundant, and a sample which was fairly representative of one of the smaller veins showed an assay value of 5,237 dols. per ton. Analysis of the ore from one of the veins composed mainly of smaltite showed from 16 to 19 per cent. of cobalt, 4 to 7 per cent. of nickel, 60 to 66 per cent. of arsenic, and 3 to 7 per cent. of sulphur. The ores are thus so rich that comparatively small veins could be worked at a handsome profit. Although no returns have yet been received, it is stated that several car-loads or ore have been shipped from this district, which realised very high values.

The following were the results of operations on the nickel-copper deposits of Ontario in 1903:—Ore mined, 203,388 tons; ore smelted, 118,470 tons; matte produced, \$924 tons; matte shipped, 10,154 tons; copper contents of matte shipped 2455 tons; nickel contents in matte, 5274 tons; value of matte shipped, 2,193,198 dols.

According to customs returns, exports of nickel in matte, &c., were as follows, in pounds:

To Great Britain	2,028,908
To United States	9,204,961
Total	11,233,869

The price of refined nickel in New York remained steady throughout the year at from 40 to 47 cents per pound.

The production of asbestos, divided into crude and mill stock, was as follows.—Crude, 4239 tons; value 509,001 dols.; mill stock, 31,996 tons; value 658,277 dols.; total, 35,635 tons; value, 1,167,278 dols. The exports of asbestos, according to Customs returns, were 37,272 tons, valued at 1,160,887 dols.

There was a somewhat increased production of natural gas in Ontario, due entirely to operations in the Welland field, production in the Essex field having dropped to very small amounts. The development of the gas field at Medicine Hat, North-West territories, seems to have been continued with much success. The gas commission of the town of Medicine Hat has now six producing wells, one of which has been put down to a depth of nearly 1000 ft., yielding 1,125,000 cub. ft. per 24 hours. The Canadian Pacific Railway Company has just completed drilling a well to a depth of 989 ft. with 4½ in. casing to 941 ft. The pressure per square inch developed in 18 hours was 525 pounds.

The production of natural rock cement shows another large decrease in 1904, the sales being only 56,814 barrels as compared with 92,252 barrels in 1903. Although a much larger quantity of Portland cement was sold in 1904, the total value, owing to the fall in price, is only slightly in excess of that in 1903. In the absence of complete returns, Portland cement statistics have been partially estimated. The following is, however, a close approximation:—Portland cement sold, 900,358 barrels, valued at 1,272,942 dols.; Portland cement manufactured, 908,990 barrels. The imports of Portland cement in 1904 were 2,746,208 cwt. This is equivalent to about 784,630 barrels of 350 lb. each, at an average price per barrel of 1.35 dols. The duty is 12.5 cents per 100 pounds.

ZINC SHEETS, NICKEL PLATED: U.S. CUSTOMS DECISION, Feb. 23, 1905.

The United States Circuit Court has decided that nickel plated zinc sheets are not dutiable as "zinc in sheets" under paragraph 192 of the tariff, but at 45 per centum *ad valorem* under paragraph 193 as "articles not specially provided for composed wholly or in part of nickel, zinc or other metals, and whether wholly or partly manufactured."—R.W.M.

XII.—FATS, FATTY OILS, Etc.

OLIVE OIL IN ITALY.

Chem. and Drug., March 25, 1905.

The following statistics relating to the importation of olive oil from France, Spain, and Tunis into Italy have been obtained from the Italian Chamber of Commerce:—

	1903.	1904.
	Quintals.	Quintals.
From France	20,740	26,732
" Spain	102,523	70,572
" Tunis	1,260	10,770
	124,523	108,074

The total imports into Italy during 1904 amounted to 125,757 quintals, and the production to 238,579 quintals (1 quintal = 50 kilos.). Of the foregoing amount 2,699,679 kilos. were imported at Leghorn, of which Spain shipped 2,084,740 kilos., France 346,569 kilos., and Tunis 268,370 kilos. The chief interest in the above figures lies in the fact that the imports from Spain during the last three or four

years have developed considerably, and especially regard to the production of fine edible oils. In this connection Spain is now looked upon as the largest producer of the finest cream olive oils, a fact which is not sufficiently known in this country.

OLIVE OIL: GERMAN CUSTOMS DECISION.

Bd. of Trade J., March 23, 1905.

Pure undenatured olive oil is dutiable under 1 of the German Tariff at 3 or 10 m. per 100 kilos. (acc. as it is imported in casks or other vessels, even with "lavat oil" or "sulphur oil," it cannot be for table purposes.

NIGER SEED OIL: U.S. CUSTOMS DECISION.

March 2, 1905.

Niger seed oil was held to be dutiable at 25 per cent *ad valorem* as an "expressed oil," under paragraph 1 of the present tariff. The claim of the importer for free as an "oil commonly used for soap making and fit for such use," was overruled, as the evidence showed it was also used as an edible oil, and for burning and eating.—R. W. M.

STEARINE PITCH: U.S. CUSTOMS DECISION.

March 7, 1905.

Stearine pitch is dutiable at 20 per cent *ad valorem* as a "manufactured article unenumerated," under 6 of the tariff. The claims of the importer for free as "Burgundy pitch," "coal tar pitch," "mineral oil," "crude vegetable substance," or "tar of wood," were all overruled.—R. W. M.

XV.—MANURES, Etc.

GUANO DEPOSITS OF PERU.

U.S. Cons. Rep. No. 2208, March 17, 1905.

By a decree of 28th December, 1904, persons concerned in digging guano between the months of February and November, inclusive, of any year shall be fined 100 per ton of the product extracted, regardless of whether or not the vessel shall have been regularly inspected by Peruvian port authorities. A repetition of the offence will render offenders liable to confiscation of their vessels as prescribed by Article 4 of the law of 17th July, 1900.

The chief guano deposits of Peru are (1) the Islands (Lobos de Afuera and Lobos de Tierra) off the coast of Eten and (2) the Chincha Islands, off the port of Callao. There are numerous minor deposits, such as the promontories, and islets of Islay, near the port of Mollendo, &c. By a contract entered into in January, 1890, the Peruvian corporation, a British syndicate, enjoys the exclusive right of exporting guano from the Chincha deposits until 3,000,000 tons shall have been exported. Peru may continue to dig guano, but only for the purpose of benefiting national agriculture. It is said that one-third of the 3,000,000 tons have already been exported by the Peruvian corporation.

XVI.—SUGAR, STARCH, Etc.

STARCH; SOLUBLE POTATO —: U.S. CUSTOMS DECISION. Feb. 28, 1905.

Soluble starch or thin boiling starch, consisting of starch modified by the action of acid was decided to be dutiable as "starch" under paragraph 285 of the tariff. An analysis of the article showed the following composition:—

Moisture, 10.45 per cent.; dextrin, dextrose and soluble in water, 9.50 per cent.; starch forming an emulsion in liquid with water at 70° C., 62.45 per cent.; forming an opalescent liquid with water at 98° C.

; starch insoluble in water at 98° C., 6-15 per cent.; residue, 0-40 per cent. article differed from white dextrin in the per cent. in, and in the large amount of starch present, also bought and sold as soluble starch. The assessment duty at 2 c. per lb. as "dextrin" under paragraph therefore overruled.—R. W. M.

XL.—BREWING, WINES, SPIRITS, Etc.

ALCOHOL TRUST IN SPAIN.

U.S. Cons. Rep. No. 2201, March 9, 1905.

Organisation of an alcohol trust (La Sociedad Alcohólera Española) has just been completed. The office at Madrid, and a capital of 16,000,000. Members bind themselves neither to establish manufacturing, nor to deal in alcohol not produced by the company. The trust is made up of most of the alcohol in Spain, of the members of the Sociedad General de Azúcar (National Sugar Company)—which brings into its manufacturing, its molasses or dregs as product and also the alcohol which it produces—and of a number of financiers which has subscribed the 4,000,000 that form the working capital. The basis is the contract entered into with the Sociedad General de Azúcar, which owns most of the sugar mills in Spain. These the combine has already acquired the best and best-situated grain distilleries, and hopes to control also the production of vinic alcohol, in order to enable the trust to completely control the market in times, such as the present year, when the low price of wine prevents industrial alcohols from competing with vinic alcohol, it has been proposed to invite the owners of vinic alcohol to join the combine; but this necessitate a very large increase in capital, and in view of many the difficulty of bringing into harmony the interests of the innumerable small distillers throughout the country would prove almost insurmountable. In the event, considerable time must elapse before the trust is able to be in a position to operate. The president of the company states that there are 54 alcohol factories, and up to the present 31 of the part of the society, the most modern and best establishments being included. The annual production of industrial alcohol is calculated to be 600,000 litres (15,850,200 gallons).

XLIN ITALY; TAXATION AND CONSUMPTION OF —.

U.S. Cons. Rep. No. 2203, March 11, 1905.

Taxation imposed in Italy on the manufacture of spirits 190 lire per 100 litres of anhydrous alcohol, at the rate of 15-56° C. Deductions are allowed of 10 per cent. on manufactures of the first category, those in which starch and starchy substances and residues of the culture and refining of sugar are used, and of 15 per cent. on manufactures of the second category, distillates of fruits, wines, dregs of pressed grapes, and other products of wineries only. Deductions on products of factories provided with meters are allowed of 25 per cent. for distillations of fruits, dregs of pressed grapes, and remains of wines, and of 30 per cent. for distillations of wines and small wines. The active societies manufacturing articles of the second category enjoy a deduction of 18 per cent., which may be increased to 28 per cent. if they distil dregs of pressed grapes or residues mentioned, and 34 per cent. if they distil wine only. The last two advantages depend, however, on the condition that the factories are furnished with meters. Complete exemption from taxation is not granted, however, to spirits derived from wine, dregs of pressed grapes, or residues from wines when properly adulterated and intended only for lighting, heating, motive power, or industrial use, and determined uses; while for spirits derived from substances not containing wine the taxation

is reduced to 15 lire per 100 litres of pure alcohol if destined for the above-mentioned purposes. During the financial year 1903-4, 17,662 hectolitres of pure alcohol were adulterated for such purposes, of which 15,077 hectolitres were from substances containing wine, and 2,585 hectolitres from other substances.

XX.—FINE CHEMICALS, Etc.

RESORCINOL: U.S. CUSTOMS DECISION.

March 9, 1905.

Resorcinol fit for medicinal use is dutiable at 25 per cent. *ad valorem* as a "medicinal coal tar preparation," under paragraph 68 of the tariff. The claim of the importer for free entry under paragraph 524 as "resorcin" was overruled.—R. W. M.

CUMARIN: U.S. CUSTOMS DECISION.

March 8, 1905.

Coumarin derived from coal tar is dutiable at 20 per cent. *ad valorem* as a "preparation of coal tar, not a colour or dye, and not medicinal," under paragraph 15 of the tariff. The assessment of duty at 25 per cent. *ad valorem*, as a "chemical compound" was overruled.—R. W. M.

QUININE SALTS: U.S. CUSTOMS DECISION.

Quinine bromide, quinine sulphate and cinchonidine salicylate were held to be free of duty as "salts of cinchona bark" under paragraph 647 of the present tariff. The assessment of duty as "medicinal preparations" at 25 per cent. *ad valorem* was erroneous.—R. W. M.

CODEINE SALTS: U.S. CUSTOMS DECISION.

March 2, 1905.

Codeine muriate, sulphate and phosphate, were held to be dutiable at 1 dol. per oz. as a "salt of opium" under paragraph 43 of the tariff. The claim of the importer for assessment at 25 per cent. *ad valorem*, under paragraphs 67, 68 or 3, was overruled.—R. W. M.

XXII.—EXPLOSIVES, MATCHES, Etc.

PIERIC ACID.

The following Order in Council, dated March 27, relative to the position of picric acid with regard to the Explosives Act, 1875, came into force on April 1:—

1. Picric acid when in process of manufacture shall (for whatever purpose used or manufactured) be deemed to be an explosive within the meaning of the said Act, subject to the following exception:—

(a.) When the picric acid is mixed with not less than half its own weight of moisture in every process of manufacture, it shall be exempt from being deemed to be an explosive within the meaning of the said Act.

2. Picric acid when kept, conveyed, imported or sold, shall (for whatever purpose used or manufactured) be deemed to be an explosive within the meaning of the said Act, subject to the following exceptions:—

(a.) Picric acid mixed with not less than half its own weight of water shall be exempt from being deemed to be an explosive within the meaning of the said Act.

(b.) Picric acid which does not fall within the exemption (a) when the quantity does not exceed 2,000 lbs. in any one ship, boat, carriage, building or place, shall be exempt from being deemed to be an explosive within the meaning of the said Act; provided that such picric acid is so kept and conveyed

as not to be liable, whether under the action of fire or otherwise, to come in contact with any substance specified in the schedule hereto, or with any fire or light capable of igniting such picric acid.

Provided also that such picric acid when dry is so packed in a substantial barrel or case that the contents cannot escape; and that no metal other than aluminium or an alloy containing not less than 90 per cent. of aluminium, is used in the construction of any package containing such picric acid, and that each barrel or case is legibly marked "Picric acid."

Picric acid when not subject to the above exemptions must be packed and marked as required by the Order of Secretary of State relating to the packing of explosives.

3. Picrates and mixtures of picric acid with any other substance (for whatever purpose used or manufactured), shall be deemed to be explosives within the meaning of the said Act, subject to the following exceptions:—

(a.) A picrate mixed with not less than half its own weight of water, shall be exempt from being deemed to be an explosive within the meaning of the said Act.

4. This Order shall come into force on the 1st April, 1905, and shall be deemed to be in lieu of the Order in Council relating to picric acid and picrates dated the 29th December, 1887, which is hereby repealed.

Schedule.

Any of the following metals or metallic oxides, namely, lead, oxide of lead, oxide of iron, potash, baryta, lime, soda, oxide of zinc, oxide of copper; and any compound of such metal or oxide (other than a metallic sulphate); or any chlorate, nitrate, or other oxidising agent; or any other substance declared by an Order of the Secretary of State to be capable of forming with picric acid a dangerous compound.

Provided that this Schedule shall not be deemed to include any metal, or oxide unavoidably formed on any metal, used in the construction of any ship, boat or carriage, or contained in any paint, where the packages containing picric acid are protected from direct contact with such metal or paint.

Patent List.

N.B.—In these lists, [A.] means "Application for Patent," and [C.S.] "Complete Specification Accepted."

Where a Complete Specification accompanies an Application, an asterisk is affixed. The dates given are (i) in the case of Applications for Patents, the dates of application, and (ii) in the case of Complete Specifications Accepted, those of the Official Journals in which acceptances of the Complete Specifications are advertised.

Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the said dates.

I.—PLANT, APPARATUS, AND MACHINERY.

- [A.] 5332. Declercq. Continuous precipitation and decantation in the treatment of liquids. March 14.
 „ 5434. McPhail. Apparatus for evaporating liquids and for drying and oxidising other materials. March 15.

- [A.] 5481. Hô Kaolin-Och Chamottefabr., and Retort furnaces.* March 15.
 „ 5593. Ray. Vacuum evaporating apparatus. March 17.
 „ 5663. Hinze. Lixiviating and washing apparatus. March 17.
 „ 5668. Spooner (Cie. pour la Fabr. des Com. et Material d'Usines à Gaz, and Fery). metric telescopes.* March 17.
 „ 5721. Parker. Crucible furnaces. March 17.
 „ 5895. Wojciechowski. Using compressed and agitating liquids, cyanides, clarifying and separating slimes from sands. &c. March 20.
 „ 5953. Elmore. Process of separating certain constituents of finely divided material by causing them to rise or float in a liquid. March 21.
 „ 5988. Schmeisser. Distilling apparatus.* March 21.
 „ 6055. Löffler and Weidle. Filtering material. March 22.
 „ 6075. Bouchand-Praceiq. Process and apparatus for collecting, aspirating, drying, cooling, and recuperating the vapours of volatile substances diluted in air [Fr. Appl., March 26, 1904]. March 22.

[C.S.] 3962 (1904). Evans. *See under X.*

- „ 7010 (1904). Haack and Sürther Maschinen-fabrik. H. Hammerschmidt. Vacuum apparatus. March 22.
 „ 8298 (1904). Fell (Bigelow). Centrifugal machine for separating liquids from solids and for filtering the separated liquids. March 22.
 „ 14,487 (1904). Breyer and von Webrstedt. L. March 22.
 „ 14,960 (1904). Prollius. Centrifugal separator. March 29.
 „ 14,961 (1904). Prollius. Centrifugal separator. March 29.
 „ 15,351 (1904). Lennox. Drying apparatus. March 29.
 „ 15,733 (1904). Lennox. Spraying device for evaporating liquids and for other purposes. March 29.
 „ 28,776 (1904). Lindemann (Gebr. Korting & Ges.). Spraying nozzles. March 22.

II.—FUEL, GAS, AND LIGHT.

- [A.] 5216. Kramers. Manufacture of illuminating gas. March 13.
 „ 5265. Mewes. Process for generating incandescent light.* March 13.
 „ 5720. R. Dempster and Sons, Ltd., and R. Gas purifiers. March 18.
 „ 5761. Holmes. Apparatus for washing and drying gases.* March 18.
 „ 5773. Ott. Apparatus for washing and purifying coal-gas and other gases. March 18.
 „ 5779. Creed. Gas burners. March 18.
 „ 5810. Blenheim and Williams. Apparatus for the production of gas. March 20.
 „ 5825. Ellis. Art of making weak gas.* March 20.
 „ 6119. Rowbotham, Booth and Osborn. Twisted producers for gas making. March 23.

6184. Greenwood and Marriott. Production of artificial fuel. March 23.
6274. Pattinson. Manufacture of bricks, briquettes, and other articles which are moulded and fired. March 24.
6297. Cutler. Gas purifiers. March 24.
- 4230 (1904). Pfeifer and Wolz. Complete combustion of solid fuel. March 29.
- 6335 (1904). Thuman. Water gas apparatus. March 22.
- 7298 (1904). Fleming. Arc lamp electrodes. March 29.
- 7299 (1904). Fleming. Arc light electrodes and methods of making same. March 29.
- 8659 (1904). Ashby. Gas making retorts. March 22.
- 10,733 (1904). Hills and Lane. Gas producing apparatus for use with fuels of a bituminous nature. March 29.
- 13,316 (1904). Everitt. Method of extracting tar and other impurities from crude illuminating, heating or power gases. March 29.
- 26,921 (1904). Weedon. Electrodes for arc lamps and method of making same. March 29.

I.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, PETROLEUM, AND MINERAL WAXES.

211. Bingham. Enrichment of hydrocarbons. March 24.

II.—COLOURING MATTERS AND DYESTUFFS.

3215. Abel (Act.-Ges. f. Anilinfabr.). Manufacture of 3,4-dichloranilinesulphonic acid. March 13.
449. Chem. Fabr. vorm. Weiler-ter-Meer. Process for the manufacture of a yellow sulphur dye. [Ger. Appl., March 24, 1904.]* March 13.
564. Johnson (Badische Anilin und Soda Fabrik). Manufacture of phenylglycine salts.* March 16.
572. Ellis (Chem. Fabr. Sandoz). Manufacture of yellow sulphur dyes. March 16.
5843. Ransford (Cassella and Co.). *See under XIII A.*
5861. Johnson (Badische Anilin und Soda Fabrik). Manufacture of azo colouring matters. March 20.
- 675 (1904). Johnson (Badische Anilin und Soda Fabrik). Manufacture of compounds suitable for use in the preparation of colouring matters. March 29.
- 9,235 (1904). Shillito (Aniline Colour and Extract Works, formerly J. R. Geigy). Manufacture of 1-diazo-2-oxy and 2-diazo-1-oxynaphthalene mono-, di and trisulphonic acids. March 22.

III.—PREPARING, BLEACHING, DYEING, AND FINISHING TEXTILES, YARNS, AND FIBRES.

209. Baxter. Solution for rendering combustible materials fire-resisting. March 13.

- [A.] 5244. Fletcher. Dyeing machines.* March 13.
- " 5296. Zeitschner. Process of bleaching textile fibres, yarns and fabrics. March 14.
- " 5842. Bradford Dyers' Association, Ltd., and Rigby. Apparatus for finishing textile fabrics. March 20.
- " 6160. Muntadas y Rovira. Continuous bleaching apparatus. [Fr. Appl., March 23, 1904.]* March 23.
- " 6215. Textile Fibres, Ltd., and Tickel. Treating rheo, ramie or china glass, flax and other similar fibres. March 24.
- " 6230. Duckworth. Dyeing, colouring and sizing in the manufacture of polished yarns of cotton or other natural or artificial fibre. March 24.
- " 6356. Linkmeyer. Devices for the manufacture of artificial silk threads.* March 25.
- [C.S.] 9946 (1904). Crosfield and Markel. Lubrication of wool in the manufacture thereof into yarn or cloth. March 29.
- " 10,005 (1904). McNaught. Machinery for scouring and washing wool and other fibrous materials. March 22.

VII.—ACIDS, ALKALIS, AND SALTS.

- [A.] 5223. Dahl. Manufacture of white lead. March 13.
- " 5882. Candau and Candau. *See under XI.*
- " 5895. Wojciechowski. *See under I.*
- " 6135. Wheelwright and Threlfall. Manufacture of amorphous phosphorus. March 23.
- " 6136. Wheelwright and Threlfall. Means for separating amorphous irona white phosphorus. March 23.
- [C.S.] 11,256 (1904). Wood-Smith. Purification of natural salts, such as alkaline carbonates, sulphates, nitrates and chlorides. March 22.
- " 20,952 (1904). Eschellmann, Harmuth, and Toy. Tentelevskago Khimichesk Zavoda. Apparatus for the manufacture of sulphuric anhydride. March 29.

VIII.—GLASS, POTTERY, AND ENAMELS.

- [A.] 6330. Fawcett, Ltd., and Fawcett. Means for making saggars for earthenware, porcelain, or like pottery ware. March 25.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

- [A.] 5513. Zellenka. *See under X.*
- " 5528. Bandy. Process of making Portland cement from slag. [Belg. Appl., Feb. 10, 1905.]* March 16.
- " 5748. Koepff. *See under XIV.*
- " 5763. Associated Portland Cement Manufacturers (1900), Ltd., and Brooks. Manufacture of cement. March 18.
- " 5765. Associated Portland Cement Manufacturers (1900), Ltd., Bamber and Layton. Manufacture of Portland cement.* March 18.

- [A.] 5912. Stourbridge Glazed Brick and Fireclay Co., Ltd., Hill and Smith. Bricks. March 21.
- .. 6321. Kilby. Kiln particularly adapted for burning cement, lime and plaster. March 25.
- .. 6347. Chalk Power Gas Synd., Ltd., and Stoneham. Manufacture of cement. March 25.
- .. 6362. Coudere. Process for treating wood to render it hard and impermeable, and to impart to it a polished surface. March 25.

[C.S.] 8619 (1904). Goldsmith. Machine for applying colours, glazing matter, &c., on tiles, bricks, and similar articles. March 22.

.. 11,398 (1904). Hargreaves. *See under XIII B.*

X.—METALLURGY.

- [A.] 5255. Boudreaux. Antifriction compositions or alloys. [Fr. Appl., March 26, 1904].* March 13.
- .. 5260. Sulman, Picard and Ballot. Ore concentration. March 13.
- .. 5271. Bernard. Extracting zinc and the like from lead and tin and its alloys. March 14.
- .. 5367. Hudson. Manufacture of charcoal iron and steel. March 14.
- .. 5492. Cowper-Coles. Manufacture of metallic calcium. March 16.
- .. 5513. Zellenka. Soldering and cementing material, and the manufacture of same. March 16.
- .. 5573. St. André. The refining of metals.* March 16.
- .. 5817. Simpson (Simpson). Direct conversion of iron into steel (a) in the blast furnace, or (b) immediately outside it. March 23.
- .. 5857. Wood and Gittings. Refining iron and other metals. March 20.
- .. 5895. Wojciechowski. *See under I.*
- .. 5970. Thompson (Merrill). Separating the heavier or coarser from the lighter or finer components of the tailings of ores or other material. March 21.
- .. 6001. Anderson. Method of and apparatus for the smelting of ores, iron, sand and the like, and subsequent conversion into steel or other metals or alloys. March 22.
- .. 6255. McIvor and Fradd. Extraction of nickel from ores. March 24.
- .. 6290. Wagner. Alloy and process of manufacturing same. March 24.
- .. 6388. Bergendal. Furnaces for calcining and burning briquettes of ore and for similar purposes. March 25.
- [C.S.] 689 (1904). Ciantar and Ciantar. Extracting gold from solution in water. March 22.
- .. 3962 (1904). Evans. Apparatus for separating liquids from solids particularly applicable to the treatment of gold-bearing slimes. March 29.
- .. 6832 (1904). Webb. *See under XI.*
- .. 7478 (1904). Rouse and Cohn. Manufacture of briquettes from powdered iron ore or iron wastes, or from iron sand or mixtures thereof for reduction in furnaces. March 29.

[C.S.] 9110 (1904). Talbot. Manufacture of iron steel. March 22.

.. 10,682 (1904). Heberlein and Hommel. Rotary furnace applicable for use in roasting ores, March 29.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

- [A.] 5425. Sulman and Picard. Electric furnace. March 15.
- .. 5648. Ashcroft. Electrolytic cells. March 15.
- .. 5882. Candau and Candau. Manufacture of limes by electrolysis of sulphates or chlorides of soda and consecutive production of caustic soda. March 20.
- .. 5918. Chamberlain and Hookman, Ltd., Holden. Electric batteries and electrolytic processes and apparatus. March 20.
- .. 5984. Price, Cox and Marshall. Electrodes adapted for use in electric furnaces.* March 21.
- C.S. 1 6832 (1904). Webb. Electrolytic extraction of metals from solutions. March 22.
- .. 27,861 (1904). Gardiner. Electric accumulator. March 29.
- .. 27,904 (1904). Gardiner. Secondary battery. March 22.

XII.—FATTY OILS, FATS, WAXES, AND SOAP.

- [A.] 5426. Gabler, Gordon and Kennedy. Process of making soap of all kinds. March 15.
- .. 5906. Wilson. Manufacture of soaps or wax compounds. March 21.
- .. 6161. Rivoir. Apparatus for the manufacture of soap. March 23.
- [C.S.] 11,436 (1904). Fischer. Manufacture of soap. March 22.
- .. 1572 (1905). De Hemptinne. Process for converting oleic acid into stearic acid and compounds. March 22.

XIII.—PIGMENTS, PAINTS; RESINS, VARNISHES, INDIA-RUBBER, Etc.

(A.)—PIGMENTS, PAINTS.

- [A.] 5223. Dahl. *See under VII.*
- .. 5760. Bowley. Method of coating materials with paint, varnish, &c., and apparatus therefor. March 18.
- .. 5843. Ransford (Cassella und Co.). Manufacture of colour lakes. March 20.
- .. 5872. Dreyfus. Paint.* March 20.
- .. 5882. Candau and Candau. *See under XI.*
- [C.S.] 11,398 (1904). Hargreaves. *See under XIII B.*

(B.)—RESINS, VARNISHES.

5760. Bowley. *See under XIII A.*
6371. Smith. Manufacture of linoleum, floor cloths, and the like. March 25.
- 11,398 (1904). Hargreaves. Manufacture of varnishes and paints for waterproofing, disinfecting, &c., also for indurating building materials. March 29.

(C.)—INDIA-RUBBER.

5965. Sine and Rosenthal. Manufacture of rubber. March 21.
- 6471 (1904). Robinson Bros., Ltd., and Clift. Method of preparing rubber solutions and the utilisation of such means and of subsequent treatment for converting waste into serviceable rubber. March 22.

—TANNING, LEATHER, GLUE, SIZE, ETC.

5748. Koepff. Apparatus for drying gelatine, glue, paste goods, bricks, woods, &c.* March 18.

XV.—MANURES, ETC.

5618. Crone, Taylor and Williams. Manufacture of fertilisers and apparatus therefor. March 17.

XVII.—BREWING, WINES, SPIRITS, ETC.

5845. Fränkel. Production of pure diastase. March 20.
5930. Pampe. Process of separating bye products of alcoholic fermentation from mash or wort.* March 21.
6253. Howe. Apparatus for oxygenating wort, beer, and other liquids. March 24.
- 5445 (1904). Frew and Dempster. Fermented beverages. March 29.
- 10,361 (1904). Aspinall and Cannon. Treatment of wort. March 22.

XVIII.—FOODS, SANITATION, WATER PURIFICATION, & DISINFECTANTS.

(A.)—FOODS.

6278. Poumay. Alimentary product.* March 24.
6373. Preston. Nutritive flour.* March 25.
- 10,211 (1904). Lawson. Preparation of a solution for use in bleaching grain and rice. March 22.
- 13,266 (1904). Craveri. Process of preserving meat. March 22.

- [C.S.] 13,651 (1904). Budde. Sterilisation of food and beverages. March 29.
- „ 1312 (1905). Blogg. Manufacture of culinary essences. March 22.

(B.)—SANITATION; WATER PURIFICATION.

- [A.] 5200. Guttman. Apparatus for purifying or softening water.* March 13.
- „ 6055. Löffler and Weidle. *See under I.*
- „ 6112. Ball. Composition for preventing and removing incrustation and corrosion in steam boilers and the like. March 23.
- [C.S.] 8857 (1904). Wanklyn and Cooper. Treatment of sewage. March 29.
- „ 8944 (1904). Adams. Filter beds for sewage. March 22.
- „ 10,867 (1904). Peschges. Purification of sewage and the like. March 22.

(C.)—DISINFECTANTS.

- [A.] 5278. Illingworth. Means for disinfecting. March 14.
- [C.S.] 11,398 (1904). Hargreaves. *See under XIII B.*

XIX.—PAPER, PASTEBOARD, ETC.

- [A.] 5214. Lilienfeld and Tedesko. Method of coating with viscose or mixtures thereof with pigments and the like and apparatus therefor. March 13.
- „ 5766. Topham. Apparatus for filtering and pumping or regulating the flow of solutions of cellulose or the like. March 18.
- „ 6079. Lagneau, Nebel and Vignès. Celluloid and process of manufacturing same. March 22.
- [C.S.] 7885 (1904). Elias. Manufacture of paper for packing and other purposes. March 22.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES AND EXTRACTS.

- [A.] 5353. Ellis (Merck). Manufacture of dialkylbarbituric acids. March 14.
- [C.S.] 11,747 (1904). Imray (Meister, Lucius and Brüning). Manufacture of new perfumes and of intermediate products therefor. March 22.
- „ 12,091 (1904). Newton (Bayer und Co.). Manufacture of pyrimidine derivatives. March 22.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

- [A.] 5780. Little. Negative plates for photographic printing. [U.S. Appl., March 19, 1904.]* March 18.
- „ 6276. Smith. Reducing agents or compositions for use in photography.* March 24.

[A.] 6340. Croft. Photography. March 25.

[C.S.] 5948 (1904). Findlay. Base or support for photographic sensitive emulsions. March 22.

XXII — EXPLOSIVES, MATCHES, ETC.

[A.] 5687. Schultz. Manufacture of a new explosive.* March 18.

[A.] 5985. Démétriade, Jonesen and Williams. Explosives. March 21.

.. 6045. Girard. Explosives. [Fr. Appl., A] 1904.* March 22.

.. 6361. Wetter (Westfälisch-Anhaltische Sprengstoff-Fabrik Akt.-Ges.). Explosives. March 22.

[C.S.] 14,480 (1904). Csipek. Explosives. March 22.

Canadian Section.

Chairman : F. J. Smale.
 Vice-Chairmen : W. H. Ellis.
 Thos. Macfarlane

Committee :

J. Watson Bain.	W. R. Lang.
Jeffrey H. Burland.	A. McGill.
Thos. Davies.	W. Lash Miller.
G. P. Greenwood.	Jas. P. Murray.
W. L. Goodwin.	Harold Van der Linde.

Hon. Treasurer : M. J. Taylor, 77, Front Street East, Toronto

Hon. Local Secretary :

Alfred Burton, 42, Front Street West, Toronto.

Liverpool Section.

Chairman : Eustace Carey.
 Vice-Chairman : Frank Tate.

Committee :

T. Lewis Bailey.	Mar. Muspratt.
G. C. Clayton.	E. L. Peck.
J. T. Courroy.	Alf. Sneatham.
A. Foden.	H. B. Stocks.
G. Watson Gray.	J. W. Towers.
C. Louquet Higgins.	

Hon. Treasurer : W. P. Thompson.

Hon. Local Secretary :

W. R. Hardwick, 13, Batavia Buildings, Hackins Hey, Liverpool.

The following take office in Sept. next :—Committee : Arthur Carey, J. Campbell Brown, Herbert E. Davies, and W. Collingwood Williams.

London Section.

Chairman : A. Gordon Salamon.
 Vice-Chairman : R. J. Friswell.

Committee :

H. G. Colman.	A. R. Ling.
J. N. Conuah.	Wm. Pearce.
Bernard Dyer.	Boverton Redwood.
Oscar Guttman.	Walter F. Reid.
J. T. Hewitt.	L. T. Thorne.
D. L. Howard.	Thos. Tyrer.
J. Leckowitsch.	Chas. Wightman.

Hon. Local Secretary :

Julian L. Baker, 7, Addison Road, Bedford Park, W.

The following take office in Sept. next :—Committee : E. J. Bevan, M. O. Forster, G. C. Jones, B. E. R. Newlands, and F. Napier Sutton.

Manchester Section.

Chairman : J. Carter Bell.
 Vice-Chairman : F. Scudder.

Committee :

J. Allan.	B. Hart.
J. Bürger.	W. B. Hart.
R. Clayton.	K. Markel.
W. H. Coleman.	W. J. Pope.
G. J. Fowler.	H. Porter.
J. Grossmann.	W. Thomson.

Hon. Local Secretary :

Julius Hübner, Asb Villa, Cheadle Hulme, Cheshire.

The following take office in Sept. next :—Chairman : G. H. Bailey. Committee : J. Barnes, R. S. Hutton, W. E. Kay, J. H. Lester, and F. Stenhouse.

Newcastle Section.

Chairman : J. T. Dunn.
 Vice-Chairman : W. L. Rennoldson.

Committee :

P. P. Bedson.	W. W. Procter.
H. S. Collins.	Geo. Sisson.
Ellwood Holmes.	Harry Smith.
H. Louis.	A. Spiller.
N. H. Martin.	C. E. Stead.
John Pattinson.	J. E. Stuart.

Hon. Local Secretary and Treasurer :

F. C. Garrett, Armstrong College, Newcastle-on-Tyne.

The following take office in Sept. next :—Chairman : H. Louis. Vice-Chairman : J. T. Dunn. Committee : W. L. Rennoldson.

New York Section.

Chairman : Russell W. Moore.
 Vice-Chairman : Geo. C. Stoue.

Committee :

L. Backeland.	Wm. McMurtrie.
Chas. Baskerville.	H. A. Metz.
Chas. F. Chandler.	Wm. H. Nichols.
V. Coblenz.	T. J. Parker.
G. Drobeg.	F. Schmiewind.
A. H. Elliott.	C. B. Zabriskie.
E. G. Love.	

Hon. Treasurer : R. C. Woodcock.

Hon. Local Secretary :

H. Schweitzer, 40, Stone Street, New York, U.S.A.

The following take office in Sept. next :—Committee : Laguel Haigh, A. C. Humphreys, Edmund H. Miller, C. Frochazka, and Walter E. Rowley.

Nottingham Section.

Chairman : J. T. Wood.
 Vice-Chairman : S. F. Burford.

Committee :

L. Archbutt.	J. O'Sullivan.
F. J. R. Carulla.	J. M. C. Paton.
R. M. Caven.	A. L. Stern.
J. Golding.	G. J. Ward.
F. Stanley Kipping.	J. White.
H. B. Mayfield.	

Hon. Treasurer : S. J. Pentecost.

Hon. Local Secretary :

S. R. Trotman, King's Walk Chambers, Parliament Street, Nottingham.

The following take office in Sept. next :—Chairman : J. M. C. Paton. Vice-Chairman : J. T. Wood. Committee : Burford, H. S. Garry, and O. Quibell.

Scottish Section.

Chairman : R. T. Thomson.
 Vice-Chairman : J. S. Macarthur.

Committee :

W. S. Curphey.	Jas. Hendrick.
L. Dobbin.	Jas. Hope.
D. B. Dott.	H. Ingle.
Thos. Ewan.	W. G. Johnston.
J. Arnold Fleming.	J. Falconer King.
W. Frew.	M. A. Parker.
G. H. Gemmell.	T. L. Patterson.
R. Hamilton.	D. J. Playfair.

Hon. Secretary and Treasurer :

Thomas Gray, c/o Gourlay and Deas, 180, Hope Street, Glasgow.

The following take office in Sept. next :—Chairman : David Perry. Committee : Robt. M. Clark, Chas. E. Fawcett, J. Ford, G. G. Henderson and Jas. McLeod.

Sydney, N.S.W., Section.

Chairman : A. Liversidge.

Committee :

W. A. Dixon.	J. A. Schofield.
J. F. Elliott.	R. Greig Smith.
L. Meggitt.	H. G. Smith.
J. Morison.	T. Steel.
A. A. Ramsay.	

Hon. Local Secretary :

T. U. Walton, Colonial Sugar Co., O'Connell Street, Sydney, N.S.W.

Yorkshire Section.

Chairman : H. R. Procter.
 Vice-Chairman : G. W. Slatter.

Committee :

W. Ackroyd.	W. M. Gardner.
C. S. Bedford.	F. W. Richardson.
J. E. Bedford.	A. Smithells.
F. Branson.	Geo. Ward.
B. A. Burrell.	Thorp Whitaker.
John W. Cobb.	

Hon. Local Secretary and Treasurer :

T. Fairley, 17, East Parade, Leeds.

The following take office in Sept. next :—Vice-Chairman : Whitaker. Committee : Saml. H. Davies, H. K. Hirst, Mackey and G. E. Scott-Smith.

Official Notices.

COMMUNICATIONS.

Authors of communications read before the Society, or of its Local Sections, are requested to take notice that Rule 43 of the Bye-laws the Society has the right of property of publication for three months of all such papers. Payment of this Bye-law renders papers liable to be selected by the Publication Committee, or ordered to be printed for the Journal, in which case no reprints can be furnished to the author.

ANNUAL GENERAL MEETING, 1905.

The Annual General Meeting will be held in London early next, and the proceedings will commence on Monday, July 10th.

In accordance with the provisions of Rule 18 of the Bye-laws, notice is hereby given that those members whose names are printed in *italics* in the list of Council members retire from their respective offices at the forthcoming Annual Meeting.

Edward Divers, F.R.S., has been nominated to the office of President under Rule 8: Dr. L. Baekeland, J. Carter Bell, Dr. J. Lewkowitch, and Mr. N. H. Nichols have been nominated Vice-Presidents under Rule 8; and Mr. Wm. H. Nichols has been nominated a President under Rule 11.

Hon. Treasurer and Hon. Foreign Secretary have been nominated for re-election to their respective offices. Members are hereby invited to nominate fit and proper persons to fill four vacancies among the ordinary members of Council. Forms for this purpose can be obtained on application, from the General Secretary, or from the Local Secretaries of the Canadian, New York, and New York Sections.

Extract from Rule 18:—"No such nomination shall be valid unless it be signed by at least ten members of the Society who are not in arrears with their subscriptions, and unless it be received by the General Secretary, at the Secretary's office, at least one month before the date of the Annual General Meeting, at which the election to which it relates takes place. Nor shall any such nomination be valid if the person nominated be ineligible for election under Rules 12 or 15. No member shall sign more than one nomination form."

INDUSTRIAL ALCOHOL COMMITTEE.

The report of this Committee, which was appointed by the Council, and of which the Exchequer in September last to be placed into the existing facilities for the use, without payment of duty, of spirit in arts and manufactures, and, in particular, into the operation of Section 8 of the Finance Act, 1902, has been published, together with the minutes of the Committee. The report will be found on page 397 of the present issue, together with a full abstract of the Appendix. Such of the Committee's proposals as need legislative sanction will be embodied in a Revenue Bill.

A meeting of the Council, held on April 25th, the following resolutions were passed:—

"That this Council welcomes the Report of the Industrial Alcohol Committee with the Blue Book containing evidence and appendixes upon which the Report is based, and resolves that a letter be sent thanking the Secretary of the Exchequer for his action in appointing the Committee, and expressing a trust that he may see fit to give legislative effect to the recommendations of the Committee at an early date."

2. "That this Council also desires to record its appreciation of the persistent efforts of Mr. Thomas Aldrich in the cause of Industrial Alcohol, and hereby tender him its thanks for his services on the Industrial Alcohol Committee."

SIXTH INTERNATIONAL CONGRESS OF APPLIED CHEMISTRY, ROME, 1906.

At a meeting of the Organising Committee of the Sixth International Congress of Applied Chemistry, held in Rome on March 2 last, Prof. E. Paterno in the chair, it was decided to divide the Congress into the same number of sections as was the case at Berlin in 1903. At the suggestion of the Presidents of foreign Committees, the date of meeting was fixed for April, 1906, during Easter week.

All communications with respect to the Congress should be addressed to the President, Prof. E. Paterno, Via Panisperna 89, Rome.

List of Members Elected.

April 25th, 1905.

- Atteaux, F. E., 176, Purchase Street, Boston, Mass., U.S.A., Dyestuff Importer.
- Baruch, Edgar, c/o American Beet Sugar Co., 123, California Street, San Francisco, Cal., U.S.A., Chemical Engineer.
- Berge, Henry vom, c/o Schoellkopf and Co., Perry and Mississippi Streets, Buffalo, N.Y., U.S.A., Manager.
- Bond, Josiah, Somerville, N.J., U.S.A., Mining Engineer.
- Brown, Prof. Adrian J., West Heath House, Northfield, near Birmingham, Professor of Brewing.
- Brown, H. J., jun., Oak Villa, Elton, Bury, Lancashire, Paper Maker.
- Burton, James K., 336, Drexel Building, Philadelphia, Pa., U.S.A., Consulting Chemist.
- Butler, T. H., Charnwood, Cotham Park, Bristol, Chemical Student.
- Byrne, F. A., Seringa Buildings, 2, Ludgate Hill, Birmingham, Director of Chemical Co.
- Cheesman, Frank Page, 92, William Street, New York City, U.S.A., Paint Manufacturer.
- Colley, Alfred, 1, Merridale Road, Wolverhampton, Steel Works Analyst.
- Crean, John F., 25, Abercromby Square, Liverpool, Oil Refiner.
- Davidson, Wm. B., 3, Vernham Road, Plumstead, S.E., Chemist.
- Donnan, Prof. F. G., Physico-Chemical Laboratory, University, Liverpool, Professor of Physical Chemistry.
- Dreyfus, Dr. Isaac, c/o Schoellkopf and Co., Perry and Mississippi Streets, Buffalo, N.Y., U.S.A., Chief Chemist.
- Duffus, W. B., Las Minas de Rio Tinto, Provincia de Huelva, Spain, Chemist.
- Dukes Bernhard, 1, Great James Street, Bedford Row, London, W.C., Patent Agent.
- Duncan, D. J. Russell, Canadian General Electrical Co., Toronto, Canada, Civil Engineer.
- Eager, Charles E., 124, High Street, Boston, Mass., U.S.A., Merchant.
- Evans, Geo. A., 832, Yonge Street, Toronto, Ontario, Canada, Pharmacist.
- Fairechild, John G., 150, Rodney Street, Brooklyn, N.Y., U.S.A., Chemist.

Findlay, Dr. Alex., The University, Birmingham, Lecturer on Physical Chemistry.
 Gummere, W., 125, East Hanover Street, Trenton, N.J., U.S.A., Chemist.
 Hawkins, Henry, Leeming Hall, Todmorden, Yorks., Gas Engineer.
 Heathcote, Henry L., Messrs. Rudge Whitworth, Ltd., Coventry, Research Chemist.
 Heymann, Dr. Fritz, 7, Elsworthy Terrace, Hampstead, N.W., Analytical Chemist.
 Hiorns, A. H., Carleon, Chester Road, Erdington, near Birmingham, Science Teacher.
 Hodgson, T. R., The Sycamores, Poulton-le-Fylde, Lancashire.
 Holcroft, Harold, Parkdale, Wolverhampton, Ironfounder.
 Hudson, O. F., The University, Birmingham, Lecturer on Metallurgy.
 Hughes, P. Vaughan, 26, Barnsley Road, Edgbaston, Birmingham, Metallurgist and Electrical Engineer.
 Jennison, James, 90, Blackburn Road, Darwen, Lancashire, Chemist.
 Johnson, Dion L., 3257 A, Texas Avenue, St. Louis, Mo., U.S.A., Analyst.
 Jones, J. Ernest, 31, Melville Road, Coventry, Analytical Chemist.
 Kaye, Frederick, Hampden House, Phoenix Street, London, N.W., Research Chemist.
 Kayser, Edwin Cuno, c/o Messrs. J. Crosfield and Sons, Ltd., Warrington, Chemist.
 King, Warren C., c/o General Chemical Co., 25, Broad Street, New York City, U.S.A., Chemical Salesman.
 Kneeland, Furman Lawrence, 21, Park Row, New York City, U.S.A., Manufacturer.
 McKenzie, Dr. Alex., The University, Birmingham, Lecturer on Chemistry.
 Methley, Bernard, 21, Clifton Mount, Rotherham, Yorks., Engineering Chemist.
 Moseley, F. A. D. II., Box 1657, Johannesburg, Transvaal, Analytical Chemist.
 Murray, William Wallace, c/o Acker Process Co., Niagara Falls, N.Y., U.S.A., Chemist.
 Murrill, Dr. Paul L., 39, Victoria Street, Westminster, S.W., Representative, E. I. du Pont Co.
 Peakes, Charles E., 176, Purchase Street, Boston, Mass., U.S.A., Treasurer, Mercantile Corporation.
 Plath, Dr. F., Deutsche Ton- und Steinzeugwerke, A. G., Berlinerstrasse 22B., Charlottenburg, Germany, Managing Director.
 Price, Dr. T. Slater, The Technical School, Birmingham, Lecturer on Chemistry.
 Pugh, John V., Rudge Whitworth, Ltd., Coventry, Works Director.
 Rigby, William T., County Analyst's Laboratory, Temple Street, Birmingham, Analyst.
 Romanes, J. W., Minas de Rio Tinto, Huelva, Spain, Technical Chemist.
 Rosenhain, Walter, 443, Gillott Road, Edgbaston, Birmingham, Chemist and Metallurgist.
 Ruttan, Prof. R. F., Medical Faculty, McGill University, Montreal, Canada, Professor of Chemistry.
 Shrewsbury, H. S., 37, King Edward's Road, Moseley, near Birmingham, Analytical Chemist.
 Stuart, H. E., 176, Purchase Street, Boston, Mass., U.S.A., Vice-President, Mercantile Corporation.
 Szegő, A. S., 38, Walker Street, Warrington, Chemist.
 Thomlinson, Wm., Seaton Carew Ironworks, West Hartlepool, Ironmaster.
 Turner, Prof. T., 355, Bristol Road, Birmingham, Professor of Metallurgy.
 Tutwiler, Carrington Cabell, 1706, North Broad Street, Philadelphia, Pa., U.S.A., Chemist.
 Twigg, Geo. F., 70, Abbey Street, Derby, Gasworks Chemist.
 Waldenberger, Charles A., c/o Independent Baking Powder Co., 322-328, Warren Street, Jersey City, N.J., U.S.A., Chemist.
 Watson, John D., Tyburn, near Birmingham, Engineer.
 Weber, Nicholas M., 727, Western Avenue, West Lynn, Mass., U.S.A., Leather Manufacturer.

Changes of Address.

When notifying new addresses, members are required to write them distinctly, and state whether the temporary or permanent. Multiplication of address also to be avoided as tending to create confusion. In sending subscriptions, the use of the form attached the application helps in the verification of address which the safe delivery of the Journal depends.

Avery, D.: all communications to Working Men's Club, Melbourne, Vic., Australia.
 Black, W. Geoffrey, 10 Wandsworth Common; Limes, New Street, Braintree, Essex.
 Bloxam, W. Popplewell; (communications) c/o Fawdon and Low, 12, Bread Street, London and (Journals) 61, Walpole Road, Boscombe.
 Brown, Dr. Arthur Lee, 1/o North Street; 213, Court Street, Baltimore, Md., U.S.A.
 Dewhurst, John A., 1/o Bradford; 13, Highfield Tarn Wood, Saltaire, Yorks.
 Dick, W. D., 1/o London; c/o Hugh Baird and Son, West George Street, Glasgow.
 Eastlake, Arthur W., 1/o Clapham Park; Grosvenor Palace Road, Streatham Hill, S.W.
 Ekenberg, Dr. M.; Journals to 40, Odengatan, Stockholm, Sweden.
 Emery, Arthur L., 1/o New Montgomery Street, Smith, Emery and Co., 426-428, Crossley Building, San Francisco, Cal., U.S.A.
 Feilmann, Dr. E., 1/o Nottingham; 112, Alexandra Road, Wimbledon, S.W.
 Foster, Jas., Exors. of late; Journal to W. F. Clouston, Teviot Place, Edinburgh.
 Georgi, Carl, 1/o New York; 12, Wilhelmstrasse, Berlin, Germany.
 Greaves, Wm., 1/o Aberaman; c/o Powell Duffry & Co., Ltd., Bye Product Works, Bargoed, near Cardiff, South Wales.
 Grosvenor, W. M., 1/o New York City; c/o Schoenfeld, Hartford and Hanna Co., Buffalo, N.Y., U.S.A.
 Gudeman, Dr. Edw., 1/o Vincennes Avenue; 903, North Dearborn, Chicago, Ill., U.S.A.

MR. EUSTACE CAREY IN THE CHAIR.

FIRING WITH COAL-DUST.

BY EUSTACE CAREY.

ort time ago, by the courtesy of the chairman of hwartzkopff Coal-Dust Firing Syndicate, I was ted to see an installation which has been erected m at Haydock, and it occurred to me that as the ing and the use of coal-dust for the production of heat w advanced to what seems to me to be a fairly tory stage, I should be justified in reporting what I saw on that occasion and what ntly can be accomplished in the way of fuel economy l-dust firing.

n dry coal-dust of sufficient fineness, it is probably e, with a strictly regulated supply of air, to burn at the utmost attainable economy of fuel will result, in addition, with the advantage of freedom from

This is how, I take it, the matter presents itself t technical men who have given attention to the t of economy of fuel. But the cost of dry coal-dust icient fineness has been hitherto a great difficulty, must confess that some years ago, when I first saw xperiments made, and had occasion to think about tter, I was strongly of opinion that the grinding coal to a sufficient degree of fineness would er not by any possibility cost less than one shilling . In this, apparently, I was mistaken, for I am nformed that grinding need not cost more than at amount; that is, not more than sixpence a ton, ing interest and depreciation.

d, by reference to Mr. William M. Barr's "Practical e on the Combustion of Coal," page 234 of the dition, that in 1876, a series of trials were conducted American Government to determine the value of a i of burning powdered fuel patented by Messrs. hey and Storer. The boiler was but a small one, ft. in diameter and 10 ft. long, and the experiments with that boiler, apparently very carefully, were ry extensive, but went to show that there was no lar advantage in using dust-coal as compared with coal. For instance, in one experiment, with this they burnt 11-113 lb. of fuel per hour per sq. ft. te room, and they evaporated 10-124 lb. of water at 3. per 1 lb. of fuel. In their experiment with ast they burnt 11-35 lb. per sq. ft. of grate room, btained an evaporation of 10-192 per 1 lb. of fuel, mber of square feet exposed to the heated gases was y more for the lump, being 442 sq. ft. for the dust, 57 for the lump. The exit gases temperature was er the lump and 382° for the dust. These experi- were, therefore, not very conclusive.

report of the American Government states the

following, with respect to the cost of pulverising . The cost of the net horse-power in average practice may be taken at 4 lb. of coal per hour. Now, the mean of experi- ments gave 1-381 net horse-power developed by the engine in pulverising the coal, and in blowing the dust into the furnace, and in pumping the feed water into the tank, which, at 4 lb. of coal per hour per horse-power, is 5-524 lb. of coal per hour, or, as the total coal consumed per hour was 66 lb., 8-37 per cent. of the total weight of coal burned. Consequently, the pulverised coal was commercially 8-37 per cent. inferior to the lump coal. In another experiment, during which lump coal was burned alone, there was required to drive the fan blowers and to pump the feed water 0-500 net horse-power, which, at 4 lb. of coal per hour per horse-power, required 2-000 lb. of coal per hour to produce it, and as the hourly consumption of coal during that experiment was 66 lb., there were consumed in producing the artificial draught and in pumping the feed water 3-06 per cent. of the total weight of coal burned. Deducting this 3-06 per cent. from the 8-37 per cent., as given in the immediately preceding paragraph, there remains 5-31 per cent. of the total weight of coal consumed, applied to the pulverisation of the coal alone. From this, it will be seen that the use of powdered fuel was more expensive than that of lump coal, about in the ratio of the cost of pulverisation, and so far the scheme was a failure." One cause of the failure, the report goes on to say, was obviously, that the arrangement would not permit of the coal-dust being burned fast enough.

Mr. Barr mentions also Stephenson's experiments, for which no date is given. His showed negative results as to evaporation, but proved that coal dust can be burned with the exact amount of air required for the combustion, without smoke. All the experiments that Mr. Barr records in his very interesting book are of comparatively short duration: 2 hours, 4 hours, 5 hours, and so on—far too short a time, I think, to establish any real knowledge of the subject.

Mr. Brian Donkin, C.E., in his very excellent book, "The Heat Efficiency of Steam Boilers," published in 1898, describes Mr. Crampton's experiments between 1868 and 1873 with powdered coal, which experiments were conducted really for the purpose of the prevention of smoke. In his book, page 180, he refers to the "Wegener" Powdered Fuel Boiler Furnace and Apparatus, and the following details of two experiments without the Wegener apparatus and of two experiments with the Wegener apparatus are reported in the *Engineer*, of May 15th, 1896:—

	Without.	With.
Total coal burnt	1600	1415
Coal burnt per hour	225	214
Moisture in coal, per cent.	9%	1-2%
Ashes	About the same	
Temperature of feedwater entering the boiler, F.	63°	48-2°
Lbs. of water evaporated per lb. of wet coal	4-05	7-46
Same calculated out from 212° F.	5-9	9-0
Water evaporated per lb. of dry coal with feedwater at 212°	6-48	9-11
Thermal efficiency of boiler	54	71
Temperature of gases at the base of the chimney	438°	412°

The smoke observed, I need not say, was very much less in the dust experiment than in the large coal experiment.

Mr. G. O. Bartlett read a paper, which appears in the *Journal of the Association of Engineering Societies*, before the Civil Engineers' Club, at Cleveland, in May, 1903. He says, "To burn coal in a powdered form successfully three things are necessary, uniformity of moisture, uniformity in size of grain, and the amount of air required for perfect combustion." He reminds us of what we all know, that coal varies very much in moisture, therefore, uniformity in moisture is necessary for any satisfactory comparative experiments, and that it is impossible to get the best results by burning large pieces of coal together with the dust. He recommends, therefore, that all coal used for firing should be reduced to grains of equal size, and for mechanical dust firing passed through a sieve of

operation. The valve on the top box then closed, and thus prevented the rush of air referred to. The valve on the bottom box was now opened automatically, and the contents were discharged into a suitable receptacle or elevator, which elevator would load the fine ash into a waggon or truck and thus a battery of boilers would have all the fine ash deposit removed entirely automatically and, consequently, could be run day and night for any period without stoppage for removal of fine ash deposit.

Mr. W. RAMSAY inquired if none of the dust escaped up the chimney. In some experiments which he had conducted some years ago, they experienced the difficulty that they smothered the neighbourhood in fine ashes.

Mr. O. E. WILSON replied that they had never experienced anything of that kind, as a very small portion would be pretty sure to come, but that could be got over by forming an expansion chamber at the foot of the chimney, or in any part of the flue passages, in order to reduce the speed of the gases at that part and thus deposit the fine ash. This was quite a simple matter; really, it was only a case of having an installation to attach it to, but he thought there would be no difficulty whatever on that score.

Mr. STOCKS inquired if there was any difficulty found with the coal-dust which was collected from the chamber. Was it not likely to contain more moisture than that passing from the cylinder?

The CHAIRMAN, in answer to the query, stated that a small percentage of coal-dust, as far as he understood, was carried away by the air which went through.

Mr. WILSON said he supposed Mr. Stocks referred to the dust that was deposited in the chamber. There was a travelling creeper chain at the bottom of that chamber close to the brickwork, and he should say this brickwork was heated to about 300 F. The heat from the combustion chamber constantly played upon this brickwork, so that the fuel coming away from that chain was practically dry; it might contain possibly a half per cent. more fuel than the coal that came out of the dryer.

The CHAIRMAN said that he understood the fuel that went through the cylinder was dried at a temperature of about 120°, but it did not follow that the furnace and the heated gases were as low as 120°; he presumed they were much higher.

Mr. WILSON said that was so; a current of air was constantly going through the drying cylinder, which kept down the temperature. They had not made actual tests of the temperature at the foot of that chamber, but they had never had any difficulty in depositing the fine particles of fuel, or any difficulty in delivering fuel from the chamber. It came out perfectly dry and perfectly ready for grinding. Any members of the Society who cared to see the system in operation at Haydock would be perfectly welcome, and those in charge would give them full particulars and answer any questions that they might like to ask.

Meeting held at the University, on Wednesday, April 12th, 1905.

MR. EUSTACE CAREY IN THE CHAIR.

THE WOOD DISTILLATION INDUSTRY.

BY MAX MUSPRATT.

The principal commercial products from the distillation of wood are charcoal, wood spirit and acetate of lime, each of which has important industrial uses.

Charcoal has its largest outlet in the iron and steel industry, but in copper foundries, sugar refineries, for water filtration, for stoves and household cooking, also in laundries, it is utilised to an extent which in the aggregate is considerable; in addition it is the basis of carbon bisulphide manufacture, the outlet for which is increasing.

Wood spirit is used for the production of varnishes,

perfumery, formaldehyde, &c., also for denaturing alcohol.

Acetate of lime is the principal raw material in the manufacture of acetic acid and acetone, and these are the raw materials for amylac acetate, chloroacetic ether and most commercial acetates.

Thus it is clear that the outlets for the various products is an increasing one, but except perhaps in Germany systematising and perpetuating of the conditions, which production can best take place has been entirely ignored, while the methods have been wasteful and extravagant to a degree.

As in the days of really cheap coal fuel economy was never considered, so has the accessibility of virgin forests tended to postpone the application of scientific methods both in the cultivation of the trees and the carrying out of the process.

At this point it is well to review the principal commercial products, remembering that the two conditions of success as far as situation is concerned are (1) cheap wood, (2) an outlet for charcoal.

In Great Britain wood distillation is at present practically confined to waste wood, especially in conjunction with bobbin works, but the great disadvantage is the quantity of waste wood available is barely sufficient to keep a thoroughly equipped plant in full work. Quantities of wood spirit are not considered worth recovering, and the brown acetate of lime produced becoming more and more difficult to market. In the United Kingdom one, perhaps two, works are well equipped and produce grey acetate of lime of good quality, but very limited quantity. The charcoal is readily marketed.

In Germany the regulation of forestry by the State and the insistence on replanting cleared areas has much to keep the wood distillation industry in a wholesome condition; in addition practically all the improvements in process have been carried out in that country, but the demand for the products is so great that at half the total consumption of acetate and wood spirit to be met by importation.

Austro-Hungary, Russia, Bosnia, Norway and Sweden, owing to their wealth in forests, have all for many years been looked upon as most promising fields for the wood industry; they were all exploited more or less by the limited Trebertrocknungsgesellschaft of Cassel, and though individually works have survived the gigantic failure of that firm the fundamental weakness, namely, the inability to market the charcoal in those countries is likely to be a serious handicap until greater all-round industrial development brings larger demand for charcoal.

It is across the Atlantic we must look for the future industrial development of wood distillation. In the United States vast tracts of virgin forest have been felled for this industry, but, unfortunately, replanting has not taken place, as the forest wealth seemed inexhaustible: now it is being gradually realised that the most accessible of the suitable timber has been used up, and every few years the works have to be moved further and further from the centres of consumption. The situation is not yet acute from this point of view (though temporarily it is very acute from another cause), but it is already giving cause for anxiety, and the world is watching keenly for some signs that the wood-distillers are looking ahead and taking steps to deal with the problem. Actual information as to the technical side is not easy to obtain, but it is doubtful if the industry so well developed as in Germany, and it is to be hoped that, both for the consumers' and producers' sake, no effort will be spared to obtain the maximum output of products for the minimum consumption of timber; and the question of replanting felled areas is one of national and even international importance.

The position in Canada is much more healthy; the virgin forests still stand in accessible localities, and the industry is in capable hands, while the outlet for charcoal has been greatly facilitated by an unprecedented development of domestic consumption, which the United States might with advantage copy. Replanting is a condition insisted upon when the forests are systematically felled, and the outlook for this industry is

la free from anxiety, especially if, as is probable, methods are brought up to date, which at present they r from being.

t new sources of supply must be looked for, and the ability of the founding of a home industry deserves serious attention. Schemes of afforestation are freely discussed from the point of view of national ities, and as relief work in times of depression in the r markets. Little has, however, been said on the trial side, and as to wood distillation nothing. On restry side the industrial chemist cannot speak with rity, but on the industrial side a *prima facie* case is made out which deserves the very earnest attention erts and public authorities who own large tracts of such as water-sheds. One of the great deterrents estry in this country has been the length of time the r has to wait for a return on his capital, and the mental advantage of wood distillation is that the is only about 30 years, which is very much shorter is required for any other industrial application of r. The woods which are the best for wood distill- are birch and beech, but coniferous woods and oak recovery of turpentine and tannin respectively are ood, while all hard woods are more or less suitable. ctual processes it is not the purpose of this paper scribe, as they can readily be found in text-books urrent literature, but for a right understanding of onomical side manufacturing balance-sheets must ren.

following is taken from actual practice in Germany— ce Sheet I. (Year of 300 days):—

Wood used—Beech.

Cost of production—	Mks.
Wood, 15,000 cub. metres	67,500
Coal, 1,425 tons at 15 mks.	21,375
Lime, 150 tons at 15 mks.	2,250
Labour, 13,200 shifts at 2.10 mks. ..	27,720
Repairs	4,000
Packages	6,000
General (including management)	17,300

Mks. 146,145

Costs—	Mks.
Charcoal, 1,650 tons at 45 mks.	74,250
Wood spirit, 99,000 kilos. at 0.55 mks.	54,450
Acetate of lime, 382 tons, at 160 mks.	61,200
Wood tar	7,500

Mks. 197,400

	Mks.
	197,400
	146,145
Gross profit	Mks. 51,255

Depreciation—	Mks.
1 per cent. on land (15,000 mks.) ..	150
2 per cent. on buildings (75,000 mks.) ..	1,500
12 per cent. on plant (165,000 mks.) ..	19,800

Mks. 21,450

Nett profit	Mks. 29,865
-------------------	-------------

e following is based on recent improvements— ce Sheet II. (Year of 300 days):—

Wood used—Birch.

Cost of production—	Mks.
Wood, 15,000 cub. metres at 4.50 mks.	67,500
(about 6,000 tons)	
Coal 900 tons at 15 mks.	13,500
Lime, 150 tons at 15 mks.	2,250
Labour, 8,400 shifts at 2.10 mks.	17,640
Repairs	4,000
Packages	6,000
General (including management)	17,300

Mks. 128,190

Costs—	Mks.
Charcoal, 1,650 tons at 45 mks.	74,250
Wood spirit, 99,000 kilos. at 0.55 mk.	54,450
Acetate of lime, 382 tons at 160 mks.	61,120
Wood tar	7,500

197,320

128,190

Gross profit	Mks. 69,130
--------------------	-------------

Depreciation—	Mks.
1 per cent. on land (9,000 mks.)	90
2 per cent. on buildings (50,000 mks.) ..	1,000
12 per cent. on plant (125,000 mks.) ..	15,000

Mks. 16,090

Nett profit	Mks. 53,120 per annum.
-------------------	------------------------

The capital involved in the first balance sheet was 265,000 mks., and in the second 184,000 mks.; the returns on capital being 11 per cent. and 35 per cent. respectively. I have also an estimated balance sheet from Canada, where with the use of pinewood a return of over 30 per cent. is expected.

The high estimates have every prospect of realisation, but it is better to confine our attention to the balance sheet from actual working, with the certainty that it will err on the low side. We can now construct a balance sheet for a hypothetical works in England, and as this paper is a suggestion for the use of waste land by afforestation, no charge for the timber is made, but the total profits from the distillation are calculated on the acre, so as to compare with results of other methods of utilisation of waste lands.

In constructing this estimated balance sheet we have to consider the following points:—

Capital (excluding all charges for the timber).—This will, of course, vary with the scale upon which the work is to be carried out. If on too small a scale, the capital charges would swamp the undertaking. The size of the plant in Balance Sheet I. is a normal one, and is, therefore, taken.

Comparing *cost of plant*, it is safe to reckon the buildings at the same price, the cheaper material of England being counterbalanced by dearer labour; but in the plant, which is chiefly of metal, it is reasonable to reckon 10 per cent. less for England. This gives:—

	£
Buildings	3,750
Plant	7,500
Total capital	£11,250

As to the *cost of working*, coal is cheaper than in Germany, but a high price is taken owing to the comparative inaccessibility of the areas contemplated. Labour in the German balance sheet is at an extremely low rate, but judging by other products, of which comparative balance sheets have been seen, at any rate in the heavy chemical industry the nett cost per ton on similar work is about the same with low German or high English wages; an increase of about 15 per cent. however is allowed.

Lime, repairs, packages and management are taken at the German figure, though packages would probably be cheaper in England.

We, therefore, have on the debit side for approximately 500,000 cb. ft. of timber per annum:—

Cost of production—	£
Coal, 900 tons at 10s.	450
Lime, 100 tons at 15s.	75
Labour	1,000
Repairs	200
Packages	500
General (including management)	860

Total manufacturing cost £2,885

Depreciation—	£
Buildings, 2 per cent.	75
Plant, 12 per cent.	900

Total debit per annum £3,860

Say £4,000 per annum.

Now, taking the *credit side*, coke is worth in England at least 10s. more per ton than the German balance sheet figure: acetate of lime is at present £2 to £3 higher, but £8 is a fair average over a term of years. Wood spirit is worth about 2s. 6d. per gallon. The revenue, therefore, would be:—

	£	s.	d.
Charcoal, 1,650 tons at 55s.	4,537	10	0
Wood spirit, 15,000 galls. at 2s. 6d.	1,875	0	0
Acetate of lime, 382 tons at 2s.	3,056	0	0
Wood tar or creosote	400	0	0

Total credit £9,868 10 0

Or a gross profit of about £6000 per annum.

Area of land.—This most important item will have to be finally established by forestry experts.

With beech wood, a rotation of 30 years should be sufficient, and on the basis of figures which I have obtained, I give with all reserve the following estimates:—

(a) Source of information, Schlich's Manual of Forestry.

Yield per acre for 100 years 15,230 cb. ft. For 30 years this would be (say) 3000 cb. ft. Therefore, for a yield of 500,000 cb. ft. the areas which would have to be felled per annum would be 168 acres.

N.B.—The above calculation ignores the first ten years' growth.

(b) Source of information—Michigan, U.S.A.

One acre yields 3500 cb. ft.: 500,000 cb. ft. is yielded by 143 acres.

In order to leave a good margin for error 200 acres per annum for 500,000 cb. ft. is taken.

On a 30 years' rotation this would involve a total area of 6000 acres.

Calculating the gross profits of the wood distillation (viz., £6000 per annum) to the acre, this would give a sum of 20s. per acre per annum for the whole estate.

As the actual expenditure on the bulk of the estate during the period of growing would be very slight, the main items of expenditure would fall on only 400 acres each year, viz., 200 acres to be planted at, say, £5 per acre, and 200 acres to be felled at, say, 25s. per acre annually, leaving £4,500 per annum as the net yield of the estate.

Another method of showing the results is profit on the timber. In stating the yield on the actual timber, it must be remembered that the whole of the timber as felled is used, and not the sawn logs only, and that only a 30 years' rotation is involved.

The net profit on 500,000 cb. ft. per annum, as shown above, is £4500, which gives a yield of 2.16d. per cb. ft., which is the value of 40 year-old wood for other purposes.

In case beechwood is not convenient to grow fir may be considered.

Fir.—Up to recent years this wood was not considered suitable for distillation, but recent developments have made this suitable for an even more promising industry, as means have been found of separating the turpentine, which gives a large additional profit.

As fir is of more rapid growth than beechwood the return per acre will be considerably greater, and I now give an estimate based on actual figures for fir or other coniferous wood.

Fir (30 years' rotation), annual consumption 500,000 cb. ft.

Capital—	£
Buildings	3,750
Plant	8,000
	£11,750

Cost of production—	£
Coal, 1,500 tons at 10s.	750
Lime, 80 tons at 15s.	60
Labour	1,500
Repairs	250
Packages	900
General, including management	1,250
	£4,710

Value of products—	£
Charcoal, 1,365 tons at 55s. per ton	3,753
Wood spirit, 6,000 gallons at 2s. 6d.	750
Acetate of lime, 153 tons at £8	1,224
Turpentine, 120 tons at £25	3,000
Tar oil, 3,000 barrels at £1	3,000

	£11,727
Less cost of production	4,710
	£7,017

Depreciation—	£
Buildings, 2 per cent.	75
Plant, 12 per cent.	960
	£1,035
Gross profit	£5,982 per annum.

It will be seen that in this case the main profit earning products are turpentine and turpentine tar oil, both

reckoned at a low figure, best turpentine having averaged £40 per ton for some years.

Area of land—30 years' rotation. The rate of growth of fir to that of beechwood is as 24 to 15. To produce 500,000 cb. ft. of fir per annum requires 125 acres on a 30 years rotation, 3750 acres, say, 4000 acres.

The distillation profits are ...	£5,927 per annum
Cost of planting and felling—	
Planting 125 acres at £5	781
Felling 125 acres at 25s.	"
Nett yield	£5,146

This gives 25s. per annum per acre, or 2.4d. per cb. ft. for 30 years' old fir.

These returns may not seem great, but if the uncultivated lands of Great Britain can be divided up into afforestation areas of from 4000—6000 acres, so as to employ by distillation employment to the extent of over 100,000 men, and revenue of from 20s. to 25s. per acre per annum, very great new source of national wealth will be tapped.

To accentuate the importance of this industry the progressive output of the United States in the two principal products, apart from charcoal, is here given:—

Production.	Wood Alcohol.	Acetate of Lime.
	Gallons.	Tons.
1880		2,943
1890	1,000,000	11,900
1900	5,000,000	38,490

The exports are also given herewith:—

Exports.	Wood Alcohol.	Acetate of Lime.
	Gallons.	Tons.
1889	388,000	17,000
1899	727,000	21,800
1900	540,000	21,000

England at present consumes a quarter to one-third of these exports and her consumption is steadily increasing.

The United States has, it is true, virgin forests, but as against that there are railway charges and sea-freight, which largely counterbalance the natural advantage. With large tracts of uncultivated land in England, the growing feeling towards afforestation from both the aesthetic and social point of view, there is added the stimulus of a profitable industry, which in its turn will foster and increase the industries depending upon these materials. At any rate, the industrial demand for up-to-date wood distillation in this country is certain and in any public scheme of afforestation should command the most careful consideration.

London Section.

Meeting held at Burlington House, on Monday, April 24, 1905.

MR. A. GORDON SALAMON IN THE CHAIR.

ON THE FORMATION OF SULPHURIC ESTERS IN THE NITRATION OF CELLULOSE, AND THE INFLUENCE ON STABILITY.

BY C. NAPIER HAKE AND REGINALD J. LEWIS.

The purification of guncotton on a manufacturing scale presents difficulties which can only be appreciated

perts directly engaged in the process, or who, from official position in relation to the supervision of the manufacture of explosives, are constantly brought into contact with the trade.

The first attempt by von Lenke to effect purification of guncotton on a manufacturing scale by a prolonged immersion of pure guncotton in running water, was unsuccessful; after eight weeks' treatment purification was incomplete.

The pulping process suggested by the late Sir Eric Abel made, for the first time, the production of guncotton possible. In spite, however, of the adoption of all well-known precautions, manufacturers are from time to time suffering severe losses, owing to the official prohibition of explosives, more especially such explosives as contain guncotton in their composition (gelatine bombs), and which are consigned to tropical or sub-tropical countries. The unpleasant duty of condemning large cargoes in Australia fell to the lot of one of the officers in his official capacity at one time with alarming frequency, and the fact of the exact cause of the changes in the quality of the explosives being unknown, often increased the difficulties and anxieties of arriving at a final decision.

In conjunction with Messrs. Nobel, of Glasgow, and other high manufacturers, experiments were made some years ago with a view of throwing light on the subject; special cartridges were selected from each consignment and divided into two halves; one portion was tested and exploded at the factory, the other portion (specially prepared) was forwarded with consignment. Careful daily readings of air and water temperatures were taken during the voyage between England and Australia, the observations extending over a period of more than two years.

The experience gained in this experiment made it possible to forecast with almost absolute certainty the probable condition of the explosive on arrival by reference to the temperature records during the voyage. When the temperature rose to, or above, 80° F. and remained several days, the samples tested in Melbourne showed a decidedly lower "heat test" than the corresponding sample originally tested in England.

It is well known that "cordite" stored in hot climates undergoes a change, in so far as the original standard of purity is lowered.

Numerable experiments made in the laboratory of Explosives Department, Melbourne, as near as possible to the temperature conditions of a voyage through the tropics, confirmed the result recorded above.

It was urged by capable and experienced chemists connected with the factories concerned, that the apparent variation in quality of the explosive was due to the action of volatile organic substances in the guncotton, which reacted on the iodide-starch paper, but which did not affect the stability of the explosive; in other words, the interpretation of the results were erroneous.

Dupré, F.R.S., at the discussion on Mr. Oscar Reissner's paper, read before this Society in 1897, also pointed out that volatile impurities being present in gelatine bombs. No new facts, however, of a character sufficiently convincing to justify a departure from a strict interpretation of the recognised official test were forthcoming.

The investigation into the more exact causes of instability was, in the first instance, started by us on the supposition that lower nitrated bodies were formed in the case of cotton, which at ordinary or slightly raised temperatures were liable to decompose.

Portions of various degrees of nitration were washed by immersion in cold running water for 14 days, known quantities of these guncottons were then transferred to wide-mouthed stoppered bottles, containing known quantities of distilled water, and subjected to the action of a copper couple for various periods of time, both at normal and at raised temperatures, the degree of decomposition being estimated by the amount of ammonia liberated.

By comparing the results of the "heat tests" of these samples so treated, with blank experiments made under identical conditions, apparently stable cottons were obtained on applying the stability test at 130° to 131° C. to one

of the cottons, it exploded violently after ten minutes without fuming.

Curves plotted to show the amount of ammonia formed at certain temperatures and within certain time limits of treatment were found to be worthless, owing to the absorption of ammonia by the guncotton. Further investigations showed that guncotton absorbs up to 0.2 per cent. of ammonia, the quantity depending on the degree of nitration of the cotton, and the temperature of the experiment.

This property of guncotton accounted for the misleading indication of stability by the "heat test," the reaction having been simply delayed by the neutralising effect of the ammonia.

In the course of the investigation it was observed:—

1. That the lower nitrated cottons were more easily washed free of acids than the higher nitrated cottons.

2. That water in which the nitrated cotton, previously washed free of acid, had been standing for some time, on re-testing gave, in some instances, a very appreciable reaction with barium chloride, in other instances no reaction; but on evaporating the latter to dryness with a drop of potash solution, igniting, and then making up to the original volume an appreciable sulphate reaction was obtained.

3. All the nitrated samples previously washed free from sulphuric acid when dried at 212° F., and re-washed with cold distilled water, yielded a very appreciable sulphate reaction with barium chloride.

The formation of sulphuric esters of cellulose by treating cellulose with sulphuric acid has long been known. "Cotton cellulose" is rapidly attacked and dissolved by concentrated sulphuric acid. The initial product may perhaps be regarded as cellulose sulphuric acid, but a rapid molecular disintegration arises, and there results a series of sulphates with the general formula $C_6H_7O_5(SO_3)_x$. The free acids are very soluble in water, but on boiling are hydrolysed quantitatively to glucose and sulphuric acid. (Cross and Bevan, "Cellulose.") A. L. Stern, in his thesis for Doctor of Science, London University, 1894, has further investigated these compounds.

Systematic experiments were now commenced, to see whether sulphuric esters were formed in the nitration of cotton. Two samples of cotton kindly supplied to us by Mr. Lundholm, of Nobel's Explosive Company, Glasgow, for the express purposes of this investigation, were chiefly worked upon, and were described as (A) "Bleached hard waste, used in the manufacture of guncotton"; (B) "Washed cops, used in the manufacture of blasting gelatine." The above samples (A) and (B) were nitrated with acids of strengths 4.3/1, 4.1/1, 9.3/1, 9.1/1, 14.3/1, 14.1/1, 19.3/1, 19.1/1. These strengths are similar to those used by Dr. Will in his interesting investigations on the stability of nitro-cellulose.*

The nitrations were carried out at the Australian Explosives and Chemical Company's Factory, Braybrook, Victoria, and the acids used were similar to those employed by the Company for the preparation of nitro-glycerine, the ratio of acid to cotton being as 50 to 1. The temperature during nitration was 72° F. Each sample of cotton was left in contact with the acids for one hour with constant stirring, the excess of acid was then squeezed out, and the resulting cellulose nitrate drowned in a large excess of water. The samples (unpulped) were then washed twice daily for 14 days in rain water, and were then transferred, thoroughly saturated with water, to wide-mouthed, stoppered bottles, and brought to the laboratory.

After standing for several days, some of the water was squeezed out of the samples and tested for sulphuric acid with barium chloride. The samples were then re-washed for four hours in a stream of running water, and returned to the bottles in a wet condition, and retested after two days. No sulphuric acid could now be detected. Two months later the test was repeated.

* Investigations as to the stability of Nitro-cellulose, by Professor Dr. W. Will (translated from the German).

Or a gross profit of about £6000 per annum.

Area of land.—This most important item will have to be finally established by forestry experts.

With beech wood, a rotation of 30 years should be sufficient, and on the basis of figures which I have obtained, I give with all reserve the following estimates:—

(a) Source of information, Schlich's Manual of Forestry.

Yield per acre for 100 years 15,230 cb. ft. For 30 years this would be (say) 3000 cb. ft. Therefore, for a yield of 500,000 cb. ft. the areas which would have to be felled per annum would be 168 acres.

N.B.—The above calculation ignores the first ten years' growth.

(b) Source of information—Michigan, U.S.A.

One acre yields 3500 cb. ft.; 500,000 cb. ft. is yielded by 143 acres.

In order to leave a good margin for error 200 acres per annum for 500,000 cb. ft. is taken.

On a 30 years' rotation this would involve a total area of 6000 acres.

Calculating the gross profits of the wood distillation (viz., £6000 per annum) to the acre, this would give a sum of 20s. per acre per annum for the whole estate.

As the actual expenditure on the bulk of the estate during the period of growing would be very slight, the main items of expenditure would fall on only 400 acres each year, viz., 200 acres to be planted at, say, £5 per acre, and 200 acres to be felled at, say, 25s. per acre annually, leaving £4,500 per annum as the net yield of the estate.

Another method of showing the results is profit on the timber. In stating the yield on the actual timber, it must be remembered that the whole of the timber as felled is used, and not the sawn logs only, and that only a 30 years' rotation is involved.

The net profit on 500,000 cb. ft. per annum, as shown above, is £4500, which gives a yield of 2-16d. per cb. ft., which is the value of 40 year-old wood for other purposes.

In case beechwood is not convenient to grow fir may be considered.

Fir.—Up to recent years this wood was not considered suitable for distillation, but recent developments have made this suitable for an even more promising industry, as means have been found of separating the turpentine, which gives a large additional profit.

As fir is of more rapid growth than beechwood the return per acre will be considerably greater, and I now give an estimate based on actual figures for fir or other coniferous wood.

Fir (30 years' rotation), annual consumption 500,000 cb. ft.

Capital—	£
Buildings	3,750
Plant	8,000
	£11,750
Cost of production—	£
Coal, 1,500 tons at 10s.	750
Lime, 80 tons at 15s.	60
Labour	1,500
Repairs	250
Package	900
General, including management	1,250
	£4,710
Value of products—	£
Charcoal, 1,365 tons at 55s. per ton	3,753
Wood spirit, 6,000 gallons at 2s. 6d.	750
Acetate of lime, 153 tons at £8	1,224
Turpentine, 120 tons at £25	3,000
Tar oil, 3,000 barrels at £1	3,000
	£11,727
Less cost of production	4,710
	£7,017

Depreciation—	£
Buildings, 2 per cent.	75
Plant, 12 per cent.	960
Total	£1,035
Gross profit	£5,982
	per annum.

It will be seen that in this case the main profit earning products are turpentine and turpentine tar oil, both

reckoned at a low figure, best turpentine having averaged £40 per ton for some years.

Area of land.—30 years' rotation. The rate of growth of fir to that of beechwood is as 24 to 15. To produce 500,000 cb. ft. of fir per annum requires 125 acres on a 30 years rotation, 3750 acres, say, 4000 acres.

The distillation profits are ...	£5,927 per annum
Cost of planting and felling—	
Planting 125 acres at £5	781
Felling 125 acres at 25s.	"
Nett yield	£5,146

This gives 25s. per annum per acre, or 2-4d. per cb. ft. for 30 years' old fir.

These returns may not seem great, but if the uncultivated lands of Great Britain can be divided up into afforestation areas of from 4000—6000 acres, so as to be by distillation employment to the extent of over 100,000 acres, and revenue of from 20s. to 25s. per acre per annum, very great new source of national wealth will be tapped.

To accentuate the importance of this industry, the progressive output of the United States in the two principal products, apart from charcoal, is here given:—

Production.	Wood Alcohol.	Acetate of Lime.
	Gallons.	Tons.
1880		2,943
1890	1,000,000	11,900
1900	5,000,000	38,490

The exports are also given herewith:—

Exports.	Wood Alcohol.	Acetate of Lime.
	Gallons.	Tons.
1889	388,000	17,000
1899	727,000	21,800
1900	540,000	21,000

England at present consumes a quarter to one-third of these exports and her consumption is steadily increasing.

The United States has, it is true, virgin forests, but against that there are railway charges and sea-freight, which largely counterbalance the natural advantage. With large tracts of uncultivated land in England, the growing feeling towards afforestation from both the aesthetic and social point of view, there is added the stimulus of a profitable industry, which in its turn will foster and increase the industries depending upon these materials. At any rate, the industrial demand for up-to-date wood distillation in this country is certain and in any public scheme of afforestation should command the most careful consideration.

London Section.

Meeting held at Burlington House, on Monday, April 24, 1905.

MR. A. GORDON SALAMON IN THE CHAIR.

ON THE FORMATION OF SULPHURIC ESTERS IN THE NITRATION OF CELLULOSE, AND THE INFLUENCE ON STABILITY.

BY C. NAPIER HAKE AND REGINALD J. LEWIS.

The purification of gun-cotton on a manufacturing scale presents difficulties which can only be appreciated

perta directly engaged in the process, or who, from official position in relation to the supervision of the manufacture of explosives, are constantly brought into contact with the trade.

The first attempt by Von Lenke to effect purification of guncotton by a prolonged immersion of pure guncotton in running water, was unsuccessful; after eight weeks' treatment purification was incomplete.

The pulping process suggested by the late Sir Eric Abel made, for the first time, the production of clean guncotton possible. In spite, however, of the adoption of all well-known precautions, manufacturers are liable to time suffer severe losses, owing to the official prohibition of explosives, more especially such explosives contain guncotton in their composition (gelatine bombs), and which are consigned to tropical or sub-tropical countries. The unpleasant duty of condemning such cargoes in Australia fell to the lot of one of the officers in his official capacity at one time with alarming frequency, and the fact of the exact cause of the changes in quality of the explosives being unknown, often increased the difficulties and anxieties of arriving at a final decision.

In conjunction with Messrs. Nobel, of Glasgow, and other high manufacturers, experiments were made some years ago with a view of throwing light on the subject; special cartridges were selected from each consignment and divided into two halves; one portion was tested and exploded at the factory, the other portion (specially prepared) was forwarded with consignment. Careful daily readings of air and water temperatures were taken during the voyage between England and Australia, the observations extending over a period of more than two years. The experience gained in this experiment made it possible to forecast with almost absolute certainty the probable condition of the explosive on arrival by reference to temperature records during the voyage. When the temperature rose to, or above, 80° F. and remained several days, the samples tested in Melbourne showed a considerably lower "heat test" than the corresponding sample originally tested in England.

It is well known that "cordite" stored in hot climates undergoes a change, in so far as the original purity and of purity is lowered.

Numerable experiments made in the laboratory of Explosives Department, Melbourne, as near as possible to the temperature conditions of a voyage through the tropics, confirmed the result recorded above.

It was urged by capable and experienced chemists connected with the factories concerned, that the apparent variation in quality of the explosive was due to the action of volatile organic substances in the guncotton which reacted on the iodide-starch paper, but which did not affect the stability of the explosive; in other words, the interpretation of the results were erroneous.

Dupré, F.R.S., at the discussion on Mr. Oscar Reissner's paper, read before this Society in 1897, also pointed out that volatile impurities being present in gelatine bombs. No new facts, however, of a character sufficiently convincing to justify a departure from a strict interpretation of the recognised official test were forthcoming.

An investigation into the more exact causes of instability was, in the first instance, started by us on the supposition that lower nitrated bodies were formed in the case of cotton, which at ordinary or slightly raised temperatures were liable to decompose.

Portions of various degrees of nitration were washed by immersion in cold running water for 14 days, known quantities of these guncottons were then transferred to wide-mouthed stoppered bottles, containing known quantities of distilled water, and subjected to the action of a copper couple for various periods of time, both at normal and at raised temperatures, the degree of decomposition being estimated by the amount of ammonia liberated.

By comparing the results of the "heat tests" of these samples so treated, with blank experiments made under similar conditions, apparently stable cottons were obtained on applying the stability test at 130° to 131° C. to one

of the cottons, it exploded violently after 40 minutes, without fuming.

Curves plotted to show the amount of ammonia formed at certain temperatures and within certain time limits of treatment were found to be worthless, owing to the absorption of ammonia by the guncotton. Further investigations showed that guncotton absorbs up to 0.2 per cent. of ammonia, the quantity depending on the degree of nitration of the cotton, and the temperature of the experiment.

This property of guncotton accounted for the misleading indication of stability by the "heat test," the reaction having been simply delayed by the neutralising effect of the ammonia.

In the course of the investigation it was observed:-

1. That the lower nitrated cottons were more easily washed free of acids than the higher nitrated cottons.
2. That water in which the nitrated cotton, previously washed free of acid, had been standing for some time, on re-testing gave, in some instances, a very appreciable reaction with barium chloride, in other instances no reaction; but on evaporating the latter to dryness with a drop of potash solution, igniting, and then making up to the original volume an appreciable sulphate reaction was obtained.
3. All the nitrated samples previously washed free from sulphuric acid when dried at 212° F., and re-washed with cold distilled water, yielded a very appreciable sulphate reaction with barium chloride.

The formation of sulphuric esters of cellulose by treating cellulose with sulphuric acid has long been known. "Cotton cellulose" is rapidly attacked and dissolved by concentrated sulphuric acid. The initial product may perhaps be regarded as cellulose sulphuric acid, but a rapid molecular disintegration arises, and there results a series of sulphates with the general formula $C_6H_{10}O_5 \cdot x(SO_4)_y$. The free acids are very soluble in water, but on boiling are hydrolysed quantitatively to glucose and sulphuric acid. (Cross and Bevan, "Cellulose.") A. L. Stern, in his thesis for Doctor of Science, London University, 1894, has further investigated these compounds.

Systematic experiments were now commenced, to see whether sulphuric esters were formed in the nitration of cotton. Two samples of cotton kindly supplied to us by Mr. Lundholm, of Nobel's Explosive Company, Glasgow, for the express purposes of this investigation, were chiefly worked upon, and were described as (A) "Bleached hard waste, used in the manufacture of guncotton"; (B) "Washed cops, used in the manufacture of blasting gelatine." The above samples (A) and (B) were nitrated with acids of strengths 4.3/1, 4.1/1, 9.3/1, 9.1/1, 14.3/1, 14.1/1, 19.3/1, 19.1/1. These strengths are similar to those used by Dr. Will in his interesting investigations on the stability of nitro-cellulose.*

The nitrations were carried out at the Australian Explosives and Chemical Company's Factory, Braybrook, Victoria, and the acids used were similar to those employed by the Company for the preparation of nitro-glycerine, the ratio of acid to cotton being as 50 to 1. The temperature during nitration was 72° F. Each sample of cotton was left in contact with the acids for one hour with constant stirring, the excess of acid was then squeezed out, and the resulting cellulose nitrate drowned in a large excess of water. The samples (unpulp) were then washed twice daily for 14 days in rain water, and were then transferred, thoroughly saturated with water, to wide-mouthed, stoppered bottles, and brought to the laboratory.

After standing for several days, some of the water was squeezed out of the samples and tested for sulphuric acid with barium chloride. The samples were then re-washed for four hours in a stream of running water, and returned to the bottles in a wet condition, and retested after two days. No sulphuric acid could now be detected. Two months later the test was repeated.

* Investigations as to the stability of Nitro-cellulose, by Professor Dr. W. Will (translated from the German).

The following table gives the result of the tests:—

Sample marked.	1. Tested with Barium Chloride several days after return from factory.	2. Tested with Barium Chloride 2 days after being washed for 4 hours in running water.	3. Tested with Barium Chloride 2 months later than No. 2 test.

19 1/1 B	do.	do.	do.

The weaker nitrating acids had a marked hardening influence on the cotton, especially in the case of sample B.

The total sulphuric acid in each sample was then estimated by the following methods:—

3–5 grms. of the cellulose nitrate were saponified in hot alkali, just sufficient to obtain complete solution; carbonate of soda crystals, or, better, the anhydrous salt, were then added (about eight times the weight of the sample), and the whole evaporated to dryness, care being taken to keep well stirred during the operation. The temperature was then gradually raised, the combustion proceeded slowly but completely; when the residue became grey it was fused in a blast (if the process is carefully conducted the addition of nitre is unnecessary) and then taken up with water, acidified with hydrochloric acid, boiled and tested with barium chloride. Blanks run with the same reagents and nitre in the place of gun-cotton, showed no sulphate reaction. The following Table shows the results obtained:—

Samples marked.	Combined Sulphur per cent. calculated as H_2SO_4 in Cellulose Nitrate.
4 3/1 A	0.44
4 3/1 B	0.39
4 1/1 A	0.39
4 1/1 B	0.32
9 3/1 A	0.37
9 3/1 B	0.35
9 1/1 A	0.30
9 1/1 B	0.30
14 3/1 A	0.54
14 3/1 B	0.44
14 1/1 A	0.26
14 1/1 B	0.22
19 3/1 A	0.67
19 3/1 B	0.79
19 1/1 A	0.22
19 1/1 B	0.26

Two possible sources of sulphate naturally suggested themselves:—(1) The presence of lead sulphate in the nitrating acids. (2) Basic sulphates of alumina, &c., in the "ash" of the cotton.

1. The absence of lead sulphate was proved by boiling the gun-cotton in ammonia acetate and testing the solution with hydrogen sulphide; also by fusing the gun-cotton with sodium carbonate and testing the resultant melt for lead.

2. The ash in the original cotton (B) was found to be 0.59 per cent., of which 0.22 per cent. was alumina containing a trace of iron. The percentage of alumina is reduced to about 0.17 on nitration.

Samples of Swedish filter paper containing about 0.1 per cent. total ash were nitrated with acids 9 3/1 under the same conditions as the cotton above, washed with cold distilled water until they showed no sulphate reaction on standing for 24 hours. On igniting some of these papers, they were found to contain 2 per cent. of calculated sulphuric acid. On extracting for three days

in the "soxhlet" with water they lost a little over half of this amount;* but, although no more could be extracted by this treatment, yet, on drying at 212° and submitting to the "heat test," they showed a reaction at once, and on rewashing the dried papers only one cold water, the washings showed a considerable amount of sulphuric acid. Treatment with acetic acid (a method which will be described further on) required a further 0.4 per cent. On again drying at 212° for two hours, and almost immediately heat testing, papers only showed a slight reaction in 24 minutes, although nearly 0.6 per cent. combined sulphuric acid was still present.

From these experiments (filter paper) it would appear that mineral matter in cotton has very little influence on the formation of sulphur compounds.

A portion of the sample marked 14 1/1 A was taken from the bottle in a wet condition and treated in a "soxhlet" extractor for 10 days, the water being changed three times, the whole of the water was then evaporated to a small volume and tested with barium chloride; almost unappreciable quantity of sulphate separated. Upon igniting a portion of the sample so treated with alkali and testing with barium chloride, a very appreciable precipitate was obtained. Another portion of the sample treated in the "soxhlet" was tested, and showed reaction only after one hour. The same sample was then dried in the water-bath at 212° and again "heat tested," when it showed an immediate reaction in a few minutes. The interpretation of results is, that the treatment in the "soxhlet" removed the last trace of free acid and that no further development of free acid takes place even at the temperature of the "heat test" so long as sufficient moisture is present to nitrated cellulose, but on removing the moisture and raising temperature, decomposition sets in and sulphuric acid is formed.

Various solvents were tried with a view of removing these sulphur compounds, viz.:—

Dilute nitric acid, hot and cold strong nitric acid fuming nitric acid (dissolving action on gun-cotton); dilute aqua regia; dilute sulphuric acid, hot and cold; dilute acetic acid, with negative, or only very slight results. Glacial acetic acid seemed, at first, to offer the best hopes of success, but owing to its gelatinising action on cellulose nitrates, it could not be used directly. The method finally adopted, was to expose the nitrate in the ordinary hygrometric state, to the action of glacial acetic acid vapours under bell jars at ordinary temperature for from 24 to 48 hours at a time, washing, drying to the hygrometric state again and repeating the process until no more sulphuric acid separates. The washing was sometimes conducted with cold water, at other times with hot water in the "soxhlet," but whether hot or cold, the liberated sulphuric acid was each time removed: the first few hundred c.c. of the wash water.†

For instance "bleached hard waste cotton" nitrated with acids 9 3/1 (9 3/1 A) cold washed (unpulped).

Total sulphur compounds determined as sulphuric acid on the dry sample equalled 0.37 (0.375 per cent. 0.38).

20 grms. of the damp sample containing 8.49 per cent. of moisture were divided into two equal portions (corresponding to 9.151 grms. of dry nitrated cotton) and a was exposed to the action of acetic acid vapour at

* The following test was made to observe whether there was originally combined or simply remained from excess of nitrating acids. If the latter was the case, then alkali ought to be present also. Six papers (cold washed) were extracted in soxhlet for 14 days with Na_2CO_3 in the receiver. The soxhlet exactly neutralised with hydrochloric acid was made up to 100 c.c. and divided into two equal portions; 100 c.c. treated with zinc copper couple for 24 hours and tested with Nessler solution found to contain less than 0.00005 grm. NH_3 — 0.00018 H₂O. The other 100 c.c.'s acidified with hydrochloric acid and tested with $JaCl_2$ gave 0.0185 grm. $BaSO_4$ = 0.0077 grm. H_2SO_4 . A ratio of over 40 sulphuric acid to 1 of nitric acid, whereas the original ratio was 3:1.

† Acetic anhydride does not appear to act as favourably as glacial acetic vapour, owing probably to its strong gelatinising action and insufficiency of water vapour for hydrolysis.

ary temperatures, from one to two and a half days time, cold washed, and the sulphuric acid determined by washings. After the eighth treatment "heat tests" were taken and the sample washed in the "soxhlet" in addition to the cold washing. The results were treated the same as *a* with the exception of exposure to acetic acid vapour.

eral samples of commercial cellulose nitrate, cordite, and blasting gelatine cotton examined were found to contain considerable quantities of sulphates soluble in water, and sulphur compounds which could not be removed, even after prolonged treatment with water or mineral acids. An estimation of the sulphuric acid remaining after the above treatment by the method fully described, gave results corresponding to as much as 19 per cent. of sulphuric acid in blasting gelatine and 0.20 per cent. in cordite cotton. The amount of sulphate removable by water was found to be largely in excess of the quantity one would expect to find in dried guncotton. Lime was present in all the samples examined, but mostly in a soluble form, very little being as carbonate, in which form it was, no doubt, usually present. The original "heat tests" were very materially on extracting the samples with water in the "soxhlet" (the treatment being continued in cases up to 48 hours) and drying at 180° F.

The above reactions are in conformity with the results previously mentioned in this paper, and from which it appears that sulphuric acid chemically combines with cellulose during nitration, probably to form esters, which decompose to esters of a more stable character, leaving less combined sulphur. The decomposition takes place partly during the prolonged purification treatment, and partly during subsequent storage of the dried explosive. The presence of small quantities of lime in the washing waters, from the nitrating acids, and the partial breaking down of sulphuric esters, no doubt, plays an important part in helping this decomposition by hydrolysis.

The difficulty of eliminating the sulphuric esters, their tendency to slowly decomposing to set free sulphuric acid, and the want of homogeneity of distribution of the chemically mixed neutralising agent throughout the samples, explain the frequently observed erratic behaviour of apparently stabilised guncotton, and of explosives of the composition of which guncotton enters, especially when they are exposed to tropical climatic conditions. It is ventured to suggest that this property of cellulose

probably offers a truer explanation of the cause of the Stowmarket explosion in 1871, when nearly 15 tons of finished guncotton stored in the factory magazines exploded spontaneously* than that arrived at on the evidence submitted at the inquiry.

Although this accident occurred many years ago, it will still be within the memory of many here present; the

details of the voluminous evidence will, however, only be remembered by a few. We propose therefore to indicate, as briefly as possible, the points which appear to conflict with the results of our investigations by reference to the evidence of the experts engaged in the enquiry and upon whose evidence mainly the verdict and the conclusions of Captain Majendie, as to the cause of the explosion, were, at the time, based.

At the enquiry, which sat for seven days, the Home Office was advised by Dr. Dupré and the late Mr. Keates; Prof. Abel gave evidence on behalf of the War Office, and Prof. Odling appeared for the Company.

In investigating the chemical causes of the explosion, it was proved that within a fortnight of the accident impure guncotton was, on two separate occasions, found to be present on the works, the cotton commencing to fume while in the process of drying. On examination, the cotton was found to contain "a notable quantity of free sulphuric acid" (up to 0.6 per cent.).

Some of this impure cotton was "present in the magazine at the time of the explosion."

As to the origin of the sulphuric acid, Prof. Abel stated that "there is nothing in guncotton from which sulphuric acid can be devolved or developed." Captain Majendie states "there was a general agreement among the chemists on this point, and we are left therefore with only one possible conclusion, viz. :—that the sulphuric acid was, by accident or design, introduced into the cotton after it had passed the tests for purity." He goes on to say that this conclusion was "found to be materially strengthened" by the evidence of the experts as to the uneven distribution of the sulphuric acid in the cotton, and the quantity of "ash" found in the impure samples, from this it was reasoned that the sulphuric acid must have been added after the pulp had left the "poucher," or in other words, after purification.

* Report on the explosion of guncotton at Stowmarket on the 11th August, 1871, by Vivian Dering Majendie, Captain, Royal Artillery (the late Sir V. D. Majendie, K.C.B.). Report and proceedings of the special committee on guncotton, addendum 27, minutes of evidence relating to the explosion of guncotton at Stowmarket.

No doubt, cotton containing "notable traces of free sulphuric acid" or sulphuric esters would not have passed the tests applied in the works laboratory without discovery. On the other hand, Captain Menon's states, "It is clear that these arrangements afforded numerous opportunities for mistakes. No one person was responsible for the samples through the various processes of selection, testing, and final passing."

Ulmic acid bodies which are closely related to the higher members of the acetic series, may also influence the stability of a not thoroughly purified cellulose nitrate. Girard states* that when hydrocellulose is heated above 80°C. it is converted into ulmic bodies, possessing acid properties. A. L. Stern doubts the accuracy of this statement,† and says that when care is taken to remove all traces of acid, no such bodies are formed, but they easily form when even traces of acid are present. From our own observations we are inclined to A. L. Stern's view.

From the constitution of cellulose, it would be reasonable to assume that the $(\text{HSO}_4)_2$ groups would take the place of the $(\text{OH})_2$ groups, just as the $(\text{NO}_3)_2$ groups do, and this, no doubt, occurs in dissolving cellulose in sulphuric acid. The sulphuric acid esters are fairly readily decomposed, whereas the nitric esters are comparatively stable.

It is probable that a cellulose containing $(\text{HSO}_4)_2$ and $(\text{NO}_3)_2$ groups would have properties midway between these two. The partial hydrolysis and replacement of some of the $(\text{HSO}_4)_2$ groups by $(\text{OH})_2$ groups would naturally give more stable compounds. A. L. Stern has shown this to be the case with cellulose sulphuric acid.‡

We hope in continuation of this research that a closer study of the action of acetic acid on the sulphur compounds in cellulose nitrate will throw more light on the conditions of their formation and of their constitution.

Since writing this paper, we have found that fuming nitric acid vapours act in the same way on hygrometric nitro-cotton as acetic acid, but whereas acetic acid vapours have to be applied many times, one treatment with nitric vapours for 48 hours is sufficient to remove practically the whole of the sulphuric esters. No doubt, any volatile acid will have the same effect, the degree depending on the concentration of the hydrogen ions which are powerful hydrolysing catalysts.

The possible formation of sulphur compounds in the process of parchmentising paper used for wrapping cartridges for blasting, has for some time occupied our attention, the results of which we propose to embody in a future communication.

In communicating to you our results at the present incomplete stage of the investigation, we feel that we are justified by the importance of the subject.

We take this opportunity of expressing our thanks to Mr. Marcus Bell for his assistance in carrying out the work; also to Mr. H. W. Gepp, of the Australian Explosives and Chemical Company, for his valuable aid and courtesy.

DISCUSSION.

The CHAIRMAN read the following communication from Dr. Dapré, who wrote as follows:—

"The authors, in the course of an investigation on the drop of the heat test, sometimes observed in cargoes of gelatinised preparations on their arrival in Australia, although they have presumably passed the usual stability tests, have apparently come to the conclusion that this is due to the presence of sulphuric esters. That the presence of such esters in any appreciable quantity would constitute a danger no one, I think, will deny. This possible cause, though previously pointed out, has not, as far as I am aware, received the attention which it apparently deserves. The point has not as yet been proved, but the authors have, at least, gone some way towards proof, and they

are to be congratulated on the ability and care displayed in working at this somewhat difficult subject.

The analyses given in the first table of the paper, however, be accepted as giving a fair picture of what might be expected in the case of a well-manufactured guncotton. In the first place, the one hour's drop followed immediately by washing, cannot, in my opinion, be taken as equivalent to the process usually adopted by manufacturers. The authors' process favours, I think, the production and subsequent retention of an undue proportion of sulphuric esters.

"I have always been of opinion that the free sulphuric acid was not, as is often assumed, due to its combining with the water formed during the reaction, but also, perhaps mainly, to the formation of sulphuric esters subsequently converted into nitric esters. In the case of nitroglycerine, the double process can indeed have been carried out. The longer then, within reasonable limits, the cotton is left in contact with the more complete, probably, will be the conversion into nitric esters.

"In the second place, the guncotton was not washed and was but imperfectly washed in cold water, and which, as is well known, is incapable of producing a good guncotton. This again would tend to leave an undue proportion of esters in the finished product. In the third place, the highest proportion of sulphuric acid left in the guncotton, presumably in the form of sulphuric acid, was only 0.79 per cent., and the amount of free sulphuric acid produced during the subsequent keeping was apparently very small.

"In conclusion, I should like to make a few remarks regarding the Stowmarket explosion which is referred to in this paper. At first sight, the authors' explanation as to the probable cause of the explosion is a cause certainly not thought of at the time, and the light of their experiments not only a very reasonable one, but also a very probable one. There are, however, great difficulties in the way of its acceptance.

"In the first place, the guncotton involved was a very recent manufacture, and in the second place, the amount of free sulphuric acid found in one 8 oz. sample, Mr. Keates and myself (nearly 0.6 per cent.) would seem that about 2 per cent. of calcium carbonate must have been neutralised, the production of not less than 1.5 per cent. of sulphuric acid from esters present in the guncotton which had passed, as far as the evidence goes, all the then accepted stability tests.‡

"Further, even assuming that a guncotton which had passed the stability tests could have contained the proportion of esters implied, the slow rate of decomposition observed by the authors during two months, presumably from esters, as shown in the second table of the paper, makes it difficult, if not impossible, to think that so large an amount of free acid could have been produced in the guncotton in question during a month.

I may add that at Stowmarket, the stability of the guncotton was tested by three methods. Firstly, the effect produced on iodised starch paper when the sample was heated in a tube at a given rate, known as the 'tube test,' similar to but not identical with our present test; secondly, by the temperature at which the sample began to give off red fumes under stipulated conditions of heating, the fuming test; and lastly, by the temperature at which it exploded, likewise under given conditions of heating.

Colour test.—No coloration to observed below 120°F.

Fuming test.—No fumes to appear below 325°F.

Exploding test.—Not to explode below 350°F."

Dr. DIVERS said the paper was of great interest from both scientific and technical points of view, and he congratulated the authors of it. His own work had been in other fields, but he might mention that the first paper

* "Hydrocellulose and its Derivatives," *Ann. Chim. Phys.* 1881 [V] 24, pp. 337–354, by A. Girard.

† "The So-called Hydrocellulose," *Transactions of the Chemical Society*, 1904, vol. 85, pp. 336–349, by A. L. Stern, D.Sc.

‡ Cellulose sulphuric acid and the products of its hydrolysis, by A. L. Stern, *Journ. Chem. Soc. Trans.*, 1895, p. 54.

§ The free sulphuric acid was present only in patches of a portion only of the whole mass, but was calculated on the total weight. It is clear, therefore, that for this acid to have been derived from esters a great part of these patches must have consisted of such esters, an incredible condition of things in a pulped guncotton which had passed through better tests than poachers, unless indeed, the whole mass was of the same composition, but had suffered only local decomposition.

published was on the spontaneous decomposition of cotton. It was remarkable that a much greater quantity of the sulphuric esters was not found in the guncotton. The explanation given was that these esters were merely transition bodies, which passed on into the nitric esters.

HODGKINSON said they all thought they knew a deal about guncotton, but, after all, what they did was very little. The method of manufacture carried on with an ordinary chemical process such as that using picric acid seemed a somewhat crude process, and he was convinced that sulphuric esters were generally present in guncotton, especially if the sample was kept and heated up after thoroughly washing. Guncotton made on the manufacturing scale, and then ground and washed, would, in most cases, if not in all, on washing, give a sulphuric acid test. Mention was made in the paper about acetic acid apparently on the guncotton, and decomposing these sulphuric esters. He thought some of these sulphuric esters were very difficult substances to hydrolyse, and were not readily enclosed by nitric esters. He thought a means of hydrolysing these esters was by using ammonia. If the gas were passed over moderately moist guncotton it would cause detonation should the temperature rise to between 75° and 90° C., but if ammonia gas was passed over moist guncottons there were very few, if not none, afterwards, when washed out with water, which gave a sulphuric acid test.

GUTTMANN said he regretted that the authors, in common with others, had overlooked the important work which had been carried out by Messrs. Cross and Bevan. These chemists found the presence of sulphuric acid in nitro-cellulose in notable quantities—up to about 10 per cent., and he understood, although they had not mentioned it, that they were aware, as others were since, that such nitro-cellulose gave inferior stability tests. This suggested that cellulose had no definite chemical constitution, containing so many groups which could be replaced by nitrous acid—indirectly confirming what he had first pointed out, namely, that there was no definite stage of nitration of guncotton—but that the whole molecule was an aggregation in which according to the amount of nitric acid introduced higher or lower products were formed. This gave an explanation of the various anomalies, not only in the nitration of cellulose, but also in its behaviour to solvents of different constitution, and in the amount of moisture nitro-cellulose could take up. He believed it would be found that the amount of the sulphuric acid in the course of nitration was not replaced by nitric acid, and according to certain theories of nitro-cellulose, one of which was the capacity for water or moisture, the nitric acid could penetrate more or less completely. Prof. Will had recently stated that the percentage of nitrogen in nitro-cellulose was the quantity of moisture it could take up was a constant, namely 14.65, so that this constant less the percentage represented the percentage of nitrogen in the cellulose. This shows that the highest nitrated cellulose could still take up 0.5 per cent. of moisture, and this may lead to further investigation. It suggested that if nitro-cellulose could absorb a certain quantity of moisture, according to its percentage of nitrogen, there must be some hindering circumstance in the nitration which prevented the nitric acid penetrating promptly. He might take this opportunity of pointing out that the process of pulping guncotton for the purpose of purification was patented by John Tonkin, jun., of Cornwall, two years previous to the publication of Frederick Abel's process. Messrs. Hake and Lewis had that by extracting their guncotton in a Soxhlet apparatus, the heat test lowered. If that treatment of heating the water up to boiling point and passing it through the nitro-cellulose he did not wonder at it. He did not think any nitro-cellulose would stand that very long time. With reference to the Stowmarket explosion, he agreed with Dr. Dupré, who although saying at the beginning of his communication, that a probable cause of the explosion had been given, disproved later on,

quite convincingly to his mind, that the formation of these small quantities of sulphuric esters could have produced the explosion. He could not believe that the mere fact of a heat test going wrong in the ordinary way, that is to say, giving nine or even six minutes instead of ten, or the presence of 0.4 or 0.6 of sulphuric esters should be the cause of such a serious conflagration. Will, Bergmann and Jauck, and others had shown that there were two things going on in nitro-cellulose when submitted to heat. The finished and properly purified nitro-cellulose might contain a very small quantity of what had been referred to as volatile constituents, which owed their presence to the present incomplete means of purification, but these had nothing to do with the stability of the guncotton. They could be readily removed, and Will, in his test of four hours' duration, proved that after a certain length of heating, the decomposition of the guncotton followed a regular curve if it were properly stable. Some authorities had expressed doubt concerning the value of the heat test. Samples of nitro-cellulose had been submitted to comparatively high temperatures for months, and no dangerous decomposition resulted. He therefore did not think the Stowmarket explosion could be due to the cause suggested.

Mr. W. D. BORLAND said the authors had rather led them to the conclusion that they must not lightly neglect the importance of the absence of sulphuric esters of cellulose. Whether they were of the importance suggested, he was not quite sure, that was a matter for further investigation; but there were two or three points which he thought as a matter of commercial practice and manufacture on the large scale seemed to bear out the authors' idea that a certain importance ought to be attached to the presence of the sulphuric esters. First of all, so far as nitration was concerned, it was not found that to obtain a certain definite product the ratio which water bore to the sulphuric acid in the mixed acids had within certain limits more effect on the resulting product than the actual percentage of nitric acid. The preliminary formation of sulphuric esters which were later converted into nitric esters was a matter of importance. Another interesting observation was that in the purification of the nitro-cellulose, previous to pulping, when the washing waters showed no trace of acidity, it was possible by applying heavy pressure upon small pieces of unpulped guncotton resting upon litmus test paper to obtain an acid reaction, which showed there was something of an acid nature still remaining in the guncotton, and it would appear that the presence of some body very slightly soluble in water, such as a sulphuric ester, might be a reasonable explanation. Formerly the impurity of nitro-cellulose was supposed to be due to grease and various encrusting materials in the cellulose before nitration. But as there was difficulty in purifying nitro-cellulose, which had been made from perfectly pure cellulose, it was not reasonable to ascribe that difficulty to the presence of grease or foreign substances, but rather to some cellulose product of lower stability than the nitro-compound.

Mr. W. F. REID said he did not agree with the authors of the paper in attributing the Stowmarket explosion to this hypothetical formation of a sulphuric ester. It was one of the most mysterious things about guncotton that, although the technical operations were carried out uniformly and with apparently the same materials, the finished products were sometimes rejected and condemned. He desired to express his complete agreement with Mr. Guttman in the condemnation of the heat test as carried out in this country. He did not think the authors had absolutely proved the presence of sulphuric esters—they assumed there was a sulphuric ester and attributed to it the reactions which they obtained. Although it was a difficult thing to do, yet if they could have isolated even a very small percentage of the sulphuric ester it would have carried more conviction. Again, the raw material they used was to some extent defective. Although they had used the cotton which was employed generally in factories, yet that cotton was itself the waste product from another industry. Now in carrying out an accurate chemical investigation and discussing traces of almost unknown

esters in a product, they ought at least to start with pure materials. The cotton waste which was used for this purpose being a waste product might be purified to a certain extent, but there were in it impurities, and he attributed to these, in many instances, he would not say in all—the difficulty of passing the heat test as it was carried out in this country. The heat test was obviously an improper one, and was not an indication of stability, for if an explosive was heated under the conditions of the heat test, it became far more stable than it was previously. There was no doubt that the sulphuric acid played some part in the stability of the nitro-cellulose produced by the nitration of cellulose with a mixture of sulphuric and nitric acids, for he had made many experiments in nitrating cellulose with nitric acid alone and obtained a purer and more stable product as a rule. And it was recommended in some recipes for manufacturing collodion cotton for photography that sulphuric acid should not be used. To use nitric acid only in the manufacture of guncotton on the large scale would not be profitable. Still, other means might be found, and the use of sulphuric acid might probably be eliminated at some future time. He did not see any evidence that the sulphuric ester should be less stable than the nitric ester, because they had products such as parchment paper in which there were traces of sulphuric acid in some combination or other, which was absolutely stable. Parchment paper could be kept for 30 years and be as good as ever; it would absorb moisture, but did not decompose.

Mr. W. MACNAB said it should not be overlooked that the cotton marked B, used in the experiments, was almost certain to be of very high grade, and would be of much purer character than cotton waste, so that in that case, at any rate, the authors were really working with a pure raw material. He did not know whether he quite correctly followed the paper in listening to it, but it seemed to him that the authors had shown that there were sulphuric esters present, and that the removal of them tended to improve the heat test, so that it might be concluded that these esters had a deleterious effect on the stability of the explosive.

Mr. C. F. CROSS found it necessary to remind the authors of their specific contribution on this subject in 1901 (Cross, Bevan and Jenks, *Ber.*, 34, 2496; this J., 1901, page 1133), in which the matter was clearly set out and emphasised in the title, *viz.*, "The reaction of cellulose with nitrating acids, and mixed esters of cellulose." Therein they showed the fixation of quantities of sulphuric acid up to 6 per cent., calculated on the original cotton (not on the nitro cotton). Being unable to isolate these nitrosulphuric esters, and therefore to characterise them more definitely, they passed to an acid of less "negative" function than nitric acid, *viz.*, acetic acid. In the later paper to which Mr. Guttman had also referred they gave a general communication in relation to the resulting aceto-sulphates. He was able to submit to the meeting a specimen film of the normal aceto-sulphate with 8.5 per cent. sulphuric acid (H_2SO_4) in combination, not as a cellulose sulphuric acid, as was the case with the bodies described by Hoening and Schubert and Stern, but as a neutral sulphuric ester. It was a body soluble in various solvents, neutral in reaction. The interesting point was that the sulphuric acid could be left in the ester, at the same time that the acetyls were saponified away. That showed how the presence of sulphuric residues in nitro-celluloses might easily come to be overlooked. The reactions of formation of these mixed esters involved general questions of equilibrium between the cellulose OH groups and a mixture of esterifying groups with which they were brought into contact. He did not wish in any sense to discount the value of this paper: it came as a confirmation from the specialist's point of view of the matter which they had published as a contribution to the general scientific question.

Mr. H. DE MOSENTHAL said at present the conclusion did not appear to be very definite, and this was not surprising in view of the difficulty of the subject. He noticed that the authors omitted to state experiments to which he attached considerable importance, namely,

that they constructed near Melbourne an isolated zinc for storing nitroglycerin explosives which did not stand the test. They left them there for months, and they found them from time to time, and as they were kept the test steadily improved. Mr. Reid stated that this was antiquated. But was it not retained because had nothing better? He felt convinced that he could submit to the authorities a heat test which was more satisfactory it would be readily accepted. The reason why the heat test went wrong at times, especially with goods sent to tropical climates, seemed to be due to the temperature, and it might be of interest to know that explosives could not be shipped in vessels which were insulated. The idea of sending out in ships which brought home frozen meat was obvious, but the Board of Trade would not allow account of the danger of spontaneous combustion of charcoal with which the insulation was made.

Dr. R. ROBERTSON said the question of the hydrolysis of the sulphate of cellulose was of considerable importance, as was well known to manufacturers, guncotton one or two boilings, although it was to all appearances neutral, continued to hydrolyse sufficiently to the washing water acid to a considerable degree. A certain number of alkaline boilings the guncotton taken as being stable, and was then sent to be put in water. This method of boiling, which was the Service method, guncotton, seemed to be founded on a rational principle and the method received confirmation from the now put before them, because not only was the elimination of the sulphuric acid ester of cellulose this acid when set free hydrolysed other unstable products, and was the means of producing an unstable nitrate of cellulose fit for storage. This method stabilising guncotton seemed to him to receive more confirmation as time went on. There might be quoted, for example, the difficulty experienced in obtaining in the same length of time a stable cellulose, when in the initial stages an alkaline liquor added to the boiling washing water. On making cotton experimentally in which the first boiling neutralised with soda, one obtained with great difficulty a guncotton of the same stability as when one boiled guncotton in its own water with frequent change of water. As an instance in which the much-calumniated Abel test indicated such an impurity, he might say that they could mix a guncotton which had been made up of pure of perfectly good cotton with an imperfectly impure guncotton, the Abel test would indicate the presence of impurity much more quickly if the sample were mixed with nitroglycerine. For that reason it was customary at Waltham Abbey to apply what was called the "heat test" to guncotton. It consisted in adding the guncotton nitroglycerine in the proportion employed for making cordite, and testing that mixture at the temperature of the guncotton heat test. They found under these conditions they had been able to pick out impurities in guncotton which were objectionable, which, if allowed to remain, would be destructive to the product. One point raised by Mr. Guttman he would like to mention. He referred to the nitro-celluloses he spoke of on a former occasion in that room. There was a low evolution of nitrogen in the Will test and at the same time a low Abel test. It was not an ordinary unimproved guncotton but a gelatinised sample, and was recognised now that the application of the Will test to gelatinised cotton was impossible. The sample was an interesting one since, in spite of the good Will test, proved, when subjected to other tests, in which the decomposition products were not removed, to be in a very unstable condition, thus confirming the indication afforded by the Abel test.

Mr. GEORGE MACDONALD wrote as follows:—The author's conclusions as to the formation of cellulose sulphuric esters during the nitration of cotton are in agreement with manufacturing experience. The water from the vats in which guncotton is boiled is, indeed, at a stage of purification at which all original adherent acids have certainly been removed, and an acid of sulphate is always found, in excess of that nor-

ent in the water, pointing at once to the gradual imposition of a cellulose sulphuric ester. At the same time, the fact must not be overlooked that there is also a net attack during purification on the nitric ester itself, since very considerable quantities of nitric oxide can be obtained from the water in which the gun cotton has been boiled, an amount in the writer's experience equivalent to a by no means negligible decimal percentage of nitrogen on the gun cotton present.

It would appear extremely probable that the stability of nitrocellulose depends on the dual attack on the nitric ester, and the lower nitric esters. The higher ratio of sulphuric acid to nitric acid in the nitrating mixture, the longer the time necessary, and the greater number of changes of water requisite, before the water in the boiling vat is obtained free from acid reaction, the beneficial hydrolysing effect, up to a certain point, on the acidic products of decomposition is undoubtedly more perfect and rapid stabilisation is thus obtained if the acid products of decomposition are kept neutralised by the continuous addition of a neutralising agent. The author's observations on the improvement of the heat test as the sulphuric esters are removed by means of a weak acid vapour are extremely interesting, and it will be of value to know if the stability tests at higher temperatures are also found to be correspondingly improved."

THE PROOF OF PERCUSSION CAPS.

BY HENRY W. BROWNSDON, B.SC., M.SC., PH.D.

the manufacture of small arms ammunition, each component part may vary within small defined limits, the quality of the finished cartridge depends to a great extent on the reduction of these to a minimum. In other words, the perfection of the whole is dependent on the perfection of the component parts.

The component parts in a cartridge (I refer here and throughout the paper to 0.303 inch small arms), those of most interest to the chemist are the cordite charge, percussion cap, and whilst the former has received searching attention, the cap has been more or less neglected. I presume that the argument has been, so long as the cartridge conforms to final tests as regards velocity, range, &c., why bother about the caps. Up to a certain point such a conclusion may be justified, but to an inquiring mind it gives but little satisfaction.

Until quite recently, practically the only method of proof on which the quality of a cap was based was by the test made on a piece of paper when fired in a special apparatus at a distance of 8½ in. from the paper. Such a test gives indication of differences—strong and weak caps—but what do the differences indicate? What causes are responsible for such irregularities?

In my experience of this method of proving caps, to go no further than to say it gives an indication of imperfectly made caps or of miss-fires, would be at least open to severe criticism. As a ready, quick, and cheap method of detecting gross defects in manufacture, it is certainly of use. It gives an effect, but of the cause, which is far more important, it tells nothing with certainty, but unfortunately the cause is often deduced from the flash mark. Thus defects attributed to wrong causes. As an example of this point, take the common deduction made in proving caps by this method. A large mark is attributed to a strong cap, i.e., one containing an abnormal heavy charge, whilst a faint mark is attributed to a weak cap, i.e., one containing less than the average charge. Assuming that the percentage of fulminate and other ingredients is the same in both caps, the above may be a wrong deduction to draw, but in a mechanical sense, such as cap composition there is always a possibility of imperfect mixing or careless filling) of a cap containing a normal charge by volume, but abnormal so the percentages of the ingredients are concerned. Using therefore a cap to contain high percentages of potassium nitrate and chlorate, and a low percentage of stibnite, the cap would give a weaker flash mark than a normal cap instead of being a weaker cap, it is a stronger cap produced by heat and pressure, and the cap would probably

be blamed for a defect which was absent, viz.: low charge. The photographs on Fig. 1 illustrate this difference, the caps marked D giving a weaker mark than A.

FIG. 1.

although from the nature of their composition they are the stronger cap. The difference in composition of these caps of course is extreme, but variations in the percentage of ingredients in certain caps may be as high as 5 per cent.—a difference quite sufficient to show marked variations in the flash mark.

Other contributory causes to the variations, noted in flashing on paper, are varnish and tin foil, but the effect of these is not so marked. A foiled cap will give a stronger flash than an unfoiled cap, and the colour of the flash mark is browner with a heavily varnished than with a lightly varnished cap.

From these few remarks it will be seen that the causes giving rise to variations in the flash of a cap are so varied that it is impossible to attribute the differences shown on the paper with certainty to any one cause, and unless the cause be known, steps cannot be taken to remedy the defect.

A few years ago a distinct advance was made in the proof of caps by Mr. W. D. Borland, who proposed methods for photographing the flashes. The results obtained with some caps are highly instructive, giving a clear insight to many features of the flash on emerging from the fire holes, but the method is not equally applicable to all makes of caps, some giving good photographs and others images so faint as to be of little use.

Flashes of four different makes of caps.

FIG. 2.

Open Aperture.

Lens Stopped Down.

Fig. 3.

Reference to the photographs on Fig. 2 illustrate this point.

The most interesting features in the flash of a cap giving a good photograph are only brought out on stopping down the lens, and with certain caps this is impossible, since by working at full aperture only an extremely faint image is obtained. In order to obtain a strong photograph of a cap containing a composition such as C, I replaced the covering of tin foil by one of aluminium powder, which was applied by suspending the powder in the varnish with which the cap was varnished, drying and then pressing. A most interesting photograph (Fig. 3) was obtained, one showing especially the need of stopping down the lens in order to see clearly what takes place during the flash of the cap. The projected incandescent solid particles, clearly shown when the lens is stopped down, are masked to a great extent when the flash is photographed working at full aperture.

To the naked eye, there is little difference between the flashes of A and D, and the photograph of a cap such as A reveals but very little of what really takes place. Were the incandescent particles of solid antimony and potassium salts actinic, a cap such as A would undoubtedly reveal as interesting results as those obtained with the aluminium covered cap I have just referred to. With caps, such as A, B and C, giving faint photographs, it is much more instructive to flash them in a dark room and observe with the naked eye than to attempt photographic methods.

Before leaving the optical methods of examination, I should like to refer briefly to a means of approximating to the duration of flash. With a cap giving a weak photograph not much can be done, but with a cap treated with aluminium powder interesting results can be obtained. The cap is flashed at right angles to, and behind a revolving disc pierced with holes of known diameter and revolving at a known speed. By having the disc focussed in a camera in front of the disc, and exposing a plate at the time of flashing the cap, on development, the spots of light appear either circular or elongated, according to the movement through which the disc has rotated during the period of flash. Measurement of the distance through which the circle of light has moved, the speed of the disc and the distance of the spot of light from the centre of the disc, provides all the data necessary for approximating to the duration of the flash. On these lines I have computed

the total duration of flash of such a cap to be about $1/30000$ th of a second.

Both flashing on paper and photographing the flash that definiteness which is only associated with figures. For a satisfactory comparison of the value of the figures such as we are considering, figures are required, and not results which are capable of ambiguous interpretation.

If a cap is faulty in any way, what are the existing causes for its defects? It may be due to a bad composition, imperfect mixing of the ingredients in an otherwise good composition, or neglect of other essential points in the manufacture.

If it can be shown that the composition used in the manufacture is one known to give good results, that the weight and percentage of each ingredient within small unavoidable limits per cap, then definite figures are obtained which go a long way to deciding its quality. These variations being known, it should then be determined what effect they have on the cap as an igniter, to what extent they influence the temperature, pressure and form of flash produced by its percussion.

The causes, due to the composition, giving rise to caps or abnormalities in otherwise good caps, should be determined analytically and the effect of these causes on the cap as an igniter, determined physically and by practical firing on the range.

THE ANALYTICAL EXAMINATION OF CAPS.

The quantities most easily and accurately obtainable are:—

- First.—Weight of Charge.
- Second.—Weight of Fulminate.
- Third.—Weight of Stibnite.

From the figures so obtained the percentage of fulminate and stibnite per cap can be determined and of chlorate and other ingredients indirectly by difference. In the determination of such small quantities of fulminate and stibnite as are contained in a cap, special methods must of necessity be used, and on the elaboration of accurate methods for these determinations, the applicability of analytical examination of caps depends. By the use of the methods given in detail below, the weight of fulminate and stibnite are obtained easily within 20 minutes of commencing the analysis, and by working on a number of caps, the time is still further curtailed. The methods being volumetric, the only weighings required are those from which the weight of charge is obtained.

First—Determination of weight of charge.—This is done by difference, first weighing the cap, and after extracting the composition, weighing the empty shell and tin foil. The difference gives the weight of composition and varnish. The weight of varnish is small, and may be determined in a number of caps, the mean being determined from the above weight found. If comparative absolute figures are required, it may be neglected, it does not affect the weight of fulminate or stibnite.

The extracting of the composition is most conveniently and completely done over a porcelain dish of about 2 capacity by squeezing with pliers and removal of loosened foil and broken composition by means of a wooden chip. Composition adhering to the shell is loosened by alcohol and washed into the dish by means of alcohol in a small wash bottle. The shell and foil are put to one side and subsequently weighed when required. It is convenient to extract the composition out of a number of caps at the same time for individual treatment.

Second—Determination of fulminate.—The composition in the dish is broken down quite fine with a flat-bottomed glass rod, and the alcohol evaporated on the water bath until the residue is moist, but not quite dry. Twenty-five c.c. of water are then added, and the composition well stirred to the bottom. After the addition of 0.5 gr. of pure sodium thiosulphate, the contents of the dish are well stirred for 2½ minutes. One drop of Methyl Orange is then added, and the solution titrated with N/20 sulphuric acid, has been standardised against weighings of 0.05—0.10 gr. of fulminate to which 25 c.c. of water is added in a porcelain

then 0.5 gr. of thiosulphate, and after stirring for minutes, titrated with the N/20 sulphuric acid. A small amount of antimony sulphide present does not interfere with the recognition of the end point. After titration, the solution is filtered through a small filter paper, which retains the antimony sulphide. *Method—Determination of Antimony Sulphide.*—The filter containing the sulphide is well washed and then transferred to a large 6 by 1 test tube. Five c.c. of strong perchloric acid are added, and the contents of the tube allowed to stand for a few seconds until the sulphide is dissolved and all the sulphuretted hydrogen driven off or absorbed; 2–3 c.c. of a saturated solution of tartaric acid are added, and the contents of the tube washed into a 100 c.c. Erlenmeyer flask. The solution is then nearly neutralised with sodium carbonate, excess of bicarbonate is removed by boiling, and after the addition of some starch solution, titrated with N/20 iodine solution. This method for small quantities of stibnite is both rapid and accurate, the error being about + 0.0003 gr. at the outside:

0.1 gr. stibnite taken gave 0.0179 gr. Sb_2S_3 found.
0.3 gr. stibnite taken gave 0.0170 gr. Sb_2S_3 found.

The accuracy is not influenced by the operations which are involved in the analysis of the composition in the cap, as the following test experiments show:—

Cap No.	Fulminate found.	Error.	Stibnite taken.	Sb_2S_3 found.	Error.
1	0.0083	— 0.0003	0.0085	0.0084	— 0.0001
2	0.0081	— 0.0001	0.0098	0.0099	+ 0.0001
3	0.0071	— 0.0003	0.0160	0.0157	— 0.0003
4	0.0066	— 0.0002	0.0099	0.0100	+ 0.0001

It will thus be seen that the tendency of this method is to give slightly low figures for the fulminate, but since the results are uniform within a negligible error, it does not detract from the value of the results as a criterion of uniformity. Applying the above methods of analysis to various caps, figures are obtained which permit of a fair estimate being made as to their relative values, as shown by uniformity and proportion of ingredients used in the composition. Figures thus obtained on four different makes of caps are summarised in a table, which I refer to later.

Modern analysis tells us a great deal, but one can imagine the difficulties giving rise to a bad cap even though the results given by analysis were excellent. In a mechanical sense such as cap composition, where the components are considerably in density, there is a tendency for segregation to take place at several stages of the manufacture, and a cap may conceivably contain a correct composition by weight, an average weight of fulminate, of nitrate, and of chlorate, and still be a bad cap if the components were not intimately mixed. Such defects would not be noticed chemically, and are best detected physically. A number of caps when fired under similar conditions will give equal amounts of heat and equal gas volumes, and only then can one be certain of their uniformity of quality. A uniform and good cap physically must necessarily be a good cap analytically, but a good cap analytically need not of necessity be a good cap, although the chances are very much in its favour of being so.

THE PHYSICAL EXAMINATION OF CAPS.

The physical characteristics most easily measured are the heat and gas volume produced on percussion, and from one may deduce relative values for temperature and pressure. The absolute values of these characteristics are difficult to determine and of more or less theoretical interest, but relative values are of equal importance to the maker and much more easily determined. What is desired is to be able to do so to compare cap against cap by a method which will give definite reliable figures for the characteristics being tabulated which will give their relative values.

With this end in view, I have devised a small apparatus which is essentially a steel cartridge case, adapted so that a thermometer can be inserted in the neck and with means of collecting the gases liberated on percussion. The base containing the cap chamber may be unscrewed to permit of recapping and cleaning. The details of construction will be more readily understood by reference to the accompanying photographs, Figs. 4 and 5. A is of thin steel about $\frac{1}{8}$ in. thick, $1\frac{1}{2}$ in. long and $\frac{3}{4}$ inch internal diameter, thickened at the top and bottom so as to take threads for the collar c, holding the thermometer and the base d holding the cap. c has a $\frac{1}{4}$ in. hole through the centre, into which the thermometer is scaled; d is an ordinary service cap chamber in steel with an octagonal collar g for a wrench, and with parts of the rim filed away on opposite sides. Through the side collar e is fastened

FIG. 4.

FIG. 5.

a small bore glass tube containing the tap f; a and b are lead washers. The threads are best lubricated by means of a thick paste of silicate of soda and asbestos powder; e is permanently fastened, whilst c and d are best unscrewed and cleaned between each determination. The cubic capacity of A with d screwed in is 3 c.c., about that of a cartridge case. The bulb of the thermometer is adjusted so as to be central, and is protected by a thin piece of copper foil wrapped round and kept in position by means of a sporting cap shell jammed over its end. By gripping the collar c with pliers, and using a spanner on the collar g, the two can be tightened up one against the other. The apparatus is used in conjunction with an ordinary rifle firing mechanism. By filing away slots in the firing

mechanism to correspond with what is left of the rim of *d*, the apparatus can be brought into position for firing by introducing the rim projections into the slots and giving a quarter turn, afterwards locking the bolt.

FIG. 6.

For measuring the gas volume a graduated tube *a* with a stopcock *c* at the top is used, along with a connected plain tube *b* for the adjustment of pressure (Fig. 6). The graduations need not be throughout the length of the tube, *S.c.c.* in tenths from the tap being sufficient. The measuring tube is connected to the side tube of the explosion vessel by means of a piece of capillary tubing bent at right angles, rubber pressure tubing being used for the connections.

Method of Use.—A cap having been pressed into the steel base piece, the base and thermometer are screwed tightly home. The apparatus is then inserted in the firing mechanism, given a quarter turn, and the bolt closed. After the level of the mercury has been adjusted so as to stand near the tap *a*, the measuring tube is connected up at *c*, *d* and *e* being open. With the enclosed air at atmospheric pressure, *d* is closed and the reading of the mercury is noted; *b* is then lowered to reduce the pressure. The cap is now fired and the rise of temperature noted on the thermometer. As soon as no further rise is noticed *d* is opened, the level of mercury in *a* and *b* adjusted, and *e* closed. The measuring apparatus is then disconnected at *c*, and may be read subsequently, although the volumes of gas measured are so small that variations of a degree or two make no appreciable difference. The steel explosion vessel is removed, thermometer and base unscrewed and cleaned, cap extracted, base recapped and fitted up again for a second experiment.

The results obtained by use of this apparatus on four different makes of caps are summarised in the appended table, and show clearly its value in determining what might be termed the physical characteristics of a cap. The effect of slight variations in manufacture such as tin foiling can be followed and figures are obtained which give an excellent indication of uniformity and quality.

As regards the uniformity, best shown by the mean differences of the figures found, the physical characteristics agree closely with the analytical, the order of merit remaining the same. A, B and C practically identical caps as regards the percentage of components, show marked differences; C contains only three-quarters of the weight of charge of either A or B, but the heat developed by C is greater or at least equal to that developed by B, and since the charge producing the heat

is smaller by a quarter the temperature must be considerably greater.

A foiled gives an average rise of temperature of 22.4°; unfoiled this falls to 20.7° C., whilst D gives 3.3° less than foiled.

Some of these seemingly contradictory results are explained when the mode of manufacture is examined and gone into carefully, different methods producing different results.

It is difficult to obtain thermometers having exact same heat capacity, and therefore the rises in temperature observed are only strictly comparative so long as the same thermometer is used, but a thermometer can be standardised against a known cap by making experiments.

The measurement of the gas volume is a secondary consideration compared with that of the heat liberated and will be found in most cases to vary directly with rise in temperature. For ordinary every day comparative testing of caps in the laboratory, therefore, the apparatus may be simplified by doing away with the tube and its appendages.

By dividing the average rise in temperature observed by the average weight of charge, figures are obtained representing the rise of temperature per gramme of charge. The heat capacity of the apparatus being a constant quantity, the rises of temperature calculated per gram of charge are proportional to the heat liberated per gram of charge.

In estimating the value of a cap as an igniter, factors besides heat are of importance, and must be considered. Heat can be generated in the percussion cap in more than one way, and may be liberated with greater or less speed. A cap dependent on a high percentage of fulminate for its heat, must generate the heat more rapidly than one dependent on a slower combustion decomposition than the detonation of fulminate. In the production of equal amounts of heat, therefore, there is a choice of methods, and the method chosen depends on the explosive we wish to ignite. In the case of gunpowder little difficulty was experienced, and not till the introduction of modern colloidal explosives that difficulty of ignition evidenced itself. The value of an igniter may be best judged by taking extreme Gun cotton, which liberates a great amount of heat rapidly, but giving wholly gaseous products of combustion, is known to be inferior as an igniter compared with gunpowder, liberating less heat, burning less rapidly, and giving a considerable quantity of solid combustion products. This points to the great value of an igniter giving solid products with a high specific heat, as against one giving purely gaseous products. In other words, an igniter liberating its heat on comparatively slow combustion lines appears to be superior to one dependent on explosion for its heat. The only explanation to be, that in the one case the solid particles are carried directly on to the surface of the explosive where they stick and give up their heat, whilst the flame of a gaseous explosive becomes cooled at the surface of the explosive and does not last long enough to ensure ignition.

Taking the duration of a cap flash to be somewhere about 1/3000th of a second, it is evident the cap does its work quickly and give the explosive no chance of throwing off its flash.

Whilst I have confined myself in this paper to referring to military caps, the methods suggested are equally applicable to sporting caps, many different of which I have critically examined with interesting results.

In conclusion, I have much pleasure in acknowledging my indebtedness to the directors of the King's Metal Co., Ltd., in whose interests this work was originally carried out, for permission to bring this mental work before you. To Mr. H. Melville belongs the credit of being one of the first to recognise the difficulties with which the problems of ignition are and it is to his initiative that I am indebted for being alighted on such an interesting field for investigation. For part of the analytical work on which my figures are based I have to thank my assistant, Mr. A. J. Green.

Summary of Figures Obtained on Four Different Makes of Caps for 0.303 Ammunition.

	A. Tin Foiled.	B. Not Foiled.	C. Tin Foiled.	D. Tin Foiled.
Age weight of charge	0.0358 gr.	0.0378 gr.	0.0277 gr.	0.0362 gr.
Mean difference	0.0012 gr.	0.0030 gr.	0.0011 gr.	0.0015 gr.
Age weight of fulminate	0.0070 gr.	0.0077 gr.	0.0051 gr.	0.0111 gr.
Mean difference	0.0002 gr.	0.0007 gr.	0.0002 gr.	0.0004 gr.
Age fulminate	19.1	20.1	19.4	31.3
Age weight of stibnite	0.0155 gr.	0.0163 gr.	0.0117 gr.	0.0087 gr.
Mean difference	0.0006 gr.	0.0011 gr.	0.0007 gr.	0.0005 gr.
Age stibnite	41.0	42.9	12.2	23.4
Age rise in temp. in °C.	22.25° C.	19.2° C.	19.75° C.	29.6° C.
Mean difference	1.13° C.	1.56° C.	1.33° C.	1.47° C.
Age rise unfolled	20.73° C.	—	—	26.3° C.
Age gas volume in c.c. at 0° C. and 760 mm.	3.71 c.c.	3.73 c.c.	2.89 c.c.	1.46 c.c.
Mean difference	0.28 c.c.	0.32 c.c.	0.29 c.c.	0.27 c.c.

DISCUSSION.

W. F. REID said that in 1881 he found when first experimenting with colloid explosives that all caps were alike, as many people seemed to think they were, or to be. A cap which gave regular results with black powder gave uncertain results with nitro-cellulose powder, he set to work to find the reason. The first instrument he used was a practical one, although not of a high degree of accuracy. It consisted of a brass tube about the length of a gun barrel, the upper half of which was cut off at the cartridge case. Pieces of gun cotton were placed across at distances of about one inch. On flashing in the gun itself, it was found that different caps from the same batch ignited a different number of strands of gun-cotton. Then came Mr. Borland's apparatus which was a useful one. It was pointed out that the flash alone did not give accurate evidence of the actual force, and if after the proposed to carry out other methods, he might find one which many years ago he found to give very definite indications. It was igniting the cap in an apparatus fitted with a U-tube filled with mercury. The action of the cap ejected a certain quantity of the mercury which gave a measure of the total gas, and at the same time of the pressure. It did not, of course, indicate the matters in the products of combustion, which were entirely of some use. Dr. Brownson had described an apparatus which would be of great use, and he only thought it would be applied to sporting caps in the same way as he had applied it to military ones, because the method was quite different. The resistance a sporting cap had to overcome on ignition was variable, whereas with the military cartridge it was uniform.

MR. BORLAND said there was no cap which could not be photographed under suitable conditions of apparatus, such conditions had an important bearing on the interpretation of results. In the second place, the method of timing the duration of the cap was one he described himself in a lecture at the United Service Institution in 1898. According to the estimation then made, he placed the duration of a cap flame at about 1/4000th of a second, which agreed very closely with what Dr. Brownson had said. As to the question of the solid incandescent core in the flame, it demanded a great deal more attention than it had received, and was of great importance, it had an effect on the specific heat, and was able to impart its explosive heat in a graduated manner. Probably it was of infinitely more value than a high gas pressure, it exerted a sort of jet action on the explosive. The method described for gauging the temperature was of a really one for gauging heat units; it depended on the mass of the thermometer and the mass of the tube, in an apparatus for comparative testing it was valuable, other similar tests.

DR. BROWNSON, in reply to Mr. Reid, said the question of timing caps presents so much in common with that of for small arms, that similar methods of examination were applicable. Whilst, however, in the case of caps used in small arms ammunition, where one is dealing with uniform conditions, it is possible to arrive

at some definite conclusion as to the best kind of cap; the problem becomes much more complicated with caps for use with the multitude of sporting powders, each presenting differences which have to be considered in the manufacture of a suitable cap.

He was afraid Mr. Borland had misconstrued his remarks relating to photographic methods of examination. Some caps gave stronger photographs than others; and when he referred to some being so faint as to be of little use, he meant from the point of view of photographically showing projected solid particles. That other inferences might be drawn from a comparison of weak and strong photographs, he did not doubt, but the conditions, especially as regards pressure, and incidentally temperature, under which the flash of a cap is photographed and under which it is fired in service, are so far removed from one another that deductions drawn from a photograph may be misleading. As a guide to the relative temperatures of the flashes, the difference shown by photographs may be of some value, but whilst the actinic rays are most active in producing the photograph, the heat rays influence it but little.

The applicability of any photographic method of approximating to the duration of flash naturally depends to a large extent on the actinic power of the flash, and whilst he did not claim originality in using a revolving disc for the measurement of time, he wished to emphasise the great advantage possessed by a strongly actinic cap over a less actinic one, where photographic methods of examination are applied.

No single method of proof will suffice for determining the quality, uniformity, or suitability of a cap for any special purpose, but a combination and summing up of several is required, and it had been his endeavour to place some further methods at the disposal of the cap maker or buyer, which may prove of value to them in determining the quality and suitability of their caps for any desired purpose.

THE DETERMINATION OF SMALL QUANTITIES OF IRON.

BY J. W. LEATHER, F.R.S., F.I.C.

Some time ago I had occasion to determine the amount of iron in some tank waters. The quantity was too small to admit the use of the usual methods, and I found that Lovibond's tintometer provided the means of measuring small quantities with considerable precision.

The two colour reactions, the ferrocyanide and the thiocyanate, are both applicable to the purpose, but it was necessary to determine the requisite quantities of the reagents, because, as is well-known, the colour of the Prussian blue is materially affected by large excess of ferrocyanide.

(A solution of ferric chloride was employed throughout, but the weight of iron is expressed as ferric oxide as being probably more convenient.) For example, 0.001 gr. ferric oxide + 0.0528 gr. ferrocyanide + 0.0048 gr. hydrochloric acid in 20 c.c. gave a light blue, but when the quantity of hydrochloric acid was increased to

0.048 gr., a deep blue was produced; with 0.528 gr. ferrocyanide the colour was green-yellow. It was obvious therefore that the quantity of reagents employed must fall within certain limits in order to produce a normal colour, and the chief object in view throughout the measurements was to determine these limits. Secondly, it would be a great advantage if the water under examination need not be diluted materially by the added reagents; and similarly, if one quantity of reagents were found suitable for all quantities of iron within the required limits, the procedure would be much simplified.

Since only a few c.c. are required for the cells of the

tintometer, 20 c.c. was adopted as a suitable volume.

It is to be noted also that the solution of ferric chloride employed was not neutral, and doubtless contained free hydrochloric acid apart from that required by the salt, but, as becomes evident from Table I., this quantity was too small to affect the resulting colour.

Ferrocyanide.—Table I. shows the results obtained with ferrocyanide, and includes (a) the quantities of materials employed, (b) their molecular relation to the cell employed, (d) the colour in terms of Lovibond's standard glasses:—

TABLE I.

0.00004	0.01056	0.0288	1	50	1500	$\frac{1}{2}$ in.	2.2	0.3
0.00004	0.01056	0.048	1	50	2500	$\frac{1}{2}$ in.	2.2	0.3

It will be seen that if the quantity of hydrochloric acid present is only about sufficient to form ferric chloride, the colour is too light, whilst if that of ferrocyanide is much too great when the amount of iron is comparatively large, the colour is also abnormal. But with 0.001 gr. ferric oxide per 20 cc. about 0.05 gr. ferrocyanide + 0.05 gr. hydrochloric acid will produce a normal colour of Blue 9 + Yellow 1—Red 3 units on Lovibond's scale. Furthermore, these quantities do not interfere with the normal colour if the amount of iron is very much less. These amounts of reagents may be expressed as one drop of concentrated hydrochloric acid plus one drop of 10 per cent. potassium ferrocyanide solution. The necessity for adding red to the

colour of the ferrocyanide was very definite with none of standard glasses; in other words, the blue glass is not as pure a blue as the ferrocyanide.

Assuming the measurements of the largest quantity of iron to be the most correct, the following brief statement of values may be deduced:—

0.001 gr. ferric oxide = 9 blue + 1 yellow — 3 red in $\frac{1}{2}$ in. cell.
 0.0001 gr. ferric oxide = 0.9 blue + 0.1 yellow — 0.3 red in $\frac{1}{2}$ in. cell.
 or 1.8 blue + 0.2 yellow — 0.6 red in $\frac{1}{2}$ in. cell.
 0.00001 gr. ferric oxide = 0.72 blue + 0.08 yellow — 0.24 red in $\frac{1}{2}$ in. cell.

The following determinations of unknown quantities of iron were made:—One drop of conc. hydrochloric acid plus one drop 10 per cent. ferrocyanide added to 2 c.c.

he sol.; found, 7.5B+8Y—2.5 R in $\frac{1}{2}$ in. cell; 1.8=4.2=0.00042 gr. iron. The actual amount present 0.0004 gr. In another case, after adding the same reagents, the reading was, Blue—12.5 degrees in the cell; 12.5/0.9=1.4—0.0014 gr. ferric oxide; amount actually present was 0.0016 gr.

thiocyanate.—Measurements made in the same way with ammonium plus hydrochloric acid yielded results recorded in Table II.

From these measurements, it will be seen that the full depth of the colour was not obtained with 0.001 gr. of ferric oxide until about 0.09 gr. thiocyanate had been added; and that whilst 0.02 gr. hydrochloric acid does not affect the colour, it is only necessary to have a slight excess present to form ferric chloride. Since a saturated solution of either ammonium or potassium thiocyanate is more than 50 per cent. strong (100 c.c. water dissolves 50 gr. amm. thiocyanate or 217 gr. pot. thiocyanate at 10° C.), it follows that 0.1 gr. of either salt would be contained in two drops of a saturated solution. In the case of natural waters containing ferric carbonate, one drop of concentrated hydrochloric acid would be sufficient to convert it into chloride.

The table also shows that the colour produced with these quantities of reagents, in the presence of even so little as 0.01 gr. ferric oxide in 20 c.c., is quite normal.

The following measurements may be deduced from Table II:—

1 gr. ferric oxide in 20 c.c.=21 red+18 yellow in $\frac{1}{2}$ in. cell.
1 gr. ferric oxide in 20 c.c.=2.1 red+1.8 yellow in $\frac{1}{2}$ in. cell, or 4.2 red+3.6 yellow $\frac{1}{2}$ in. cell.
0.1 gr. ferric oxide in 20 c.c.=0.42 red+0.36 yellow in $\frac{1}{2}$ in. cell, or 0.84 red+0.72 yellow in 1 in. cell.

The following determinations were made with unknown quantities of iron in 20 c.c.:—

1. Observed, 3.3 R+3 Y in 1 in. cell. 3.3 0.84=4=0.4 gr. ferric oxide; actual amount present=0.000043 gr.
2. Observed, 5.3 R+4.2 Y in 1 in. cell. 5.3 0.84=6.3=0.63 gr. ferric oxide; actual amount present=0.00007 gr.
3. Observed, 15.7 R. in $\frac{1}{2}$ in. cell. 15.7/2.1=7.5=0.00075 gr. ferric oxide; actual amount present=0.0008 gr.
4. Observed, 10.3 R. in $\frac{1}{2}$ in. cell. 10.3/2.1=4.9=0.00049 gr. ferric oxide; actual amount present 0.0005 gr.

In the two reactions, the thiocyanate is perhaps to be regarded. It is distinctly more delicate with small quantities of iron; even so little as 0.00001 gr. may be indicated with very considerable accuracy. A further advantage lies in the fact that only two sets of glasses, red and yellow, are required to match the colour of the thiocyanate, whereas with the ferrocyanide all three have to be employed. When employing ferrocyanide five to ten minutes should be given for the full development of the colour; but the reaction with thiocyanate appears to be almost instantaneous.

It is also to be noted that the normal colour of ferrocyanide is produced in the presence of two equivalents of ferrocyanide to one atom of iron that is the theoretical amount, but that some free hydrochloric acid must be present. With the thiocyanate about 100 mols. of iron is necessary to produce the full depth of colour, whereas only 12 mols. should be required to form $9\text{NH}_4\text{CSN.Fe}(\text{CSN})_3$, and points to the necessity of a salt of greater complexity than this one.

adopted only after the most patient investigation and serious consideration. To-day this is certainly not the case. No great industry has changed so radically in the last two decades as has the art of leather making, and in none are experiments made on so large a scale or in general with so little preliminary investigation. Two causes have operated to produce this change: 1st, the successful introduction and development of chrome tanning; 2nd, the diminishing supply of tan bark, and consequent necessary introduction of tanning extracts. With an industry in this restless state, all possible ways for improvement are searched for and examined with avidity, and the question of shortening the time required for producing these leathers which from their nature cannot be made by the quick chrome methods, becomes one of paramount interest.

Sole leathers require a firmness and solidity of texture which is not obtainable by the use of mineral tanning agents, or at least by such agents alone. In former times one to three years was the time allowed for tanning good sole leather, and in fact there are records of the hides being permitted to remain in the pits for seven years. To-day I would put seven months as the longest time and four or five months the average time for the production of the best quality of sole leather, and from these periods down to two or three days may be called the limit of variation. For the purpose of my paper I make the arbitrary distinction that a quick process of sole leather tanning is one that is completed, and the leather ready for the market, inside of thirty or forty days.

The value of a successful quick tanning process is perhaps self-evident in the saving of investment and interest which it would effect; but there is another condition of more recent origin which is causing greater urgency for quick returns in leather making, namely, the close control of the hide market by the large packing interests, and the attendant speculative fluctuations which are certainly not to the advantage of the old-fashioned tanner, with hundreds or thousands of dollars tied up for months in unfinished leather. Hence, we find to-day a very large amount of money invested in experimental processes of quick tanning. While the majority of these processes are more or less protected by patents, they should to a large extent be classed as secret processes, as the patents usually cover only minor details, and to my mind, may be avoided in general by a little mechanical ingenuity, and with equally good results. Another, and perhaps the most important point is the personal factor. Many men to-day are making merchantable leather by quick processes, while others who are not such keen observers nor as painstaking manufacturers, are making expensive failures with as good if not better processes.

The history of quick tanning dates back not earlier than 1880, and because of its influence on the sole leather manufacturer, I wish to include in my paper a slight account of the light leather quick tannages. The first of these was the Dongola process, or what we call to-day a "combination tannage," that is, salt, alum, and gambier. This is completed in a shorter time than was then employed with vegetable tannage alone, and is important because it brought into general use revolving drums, and paddle vats. Then followed the chrome tanning by the Schultz method, and its successors, the one bath processes of Martin Dennis, Procter, and many others. Two points may be noticed here: 1st, that with the chrome process the development of mechanical agitation begun by the Dongola process was rapidly increased; 2nd, that the direction of progress in chrome tanning has been from light to heavy leathers. At first goat and kid skins only were successfully chrome tanned, then followed chrome sheep and calf leather. Less than five years ago chrome sole leather became an article of commerce, and within the last year or two chrome tanned belt leather has been produced and used in steadily increasing quantity.

True quick tanning of sole leather begins with the Velocitan process of Fratri Durio,* which swept Europe

New York Section.

Meeting held at the Chemists' Club, on Friday,
January 20th, 1905.

DR. RUSSELL W. MOORE IN THE CHAIR.

WICK PROCESS TANNING OF SOLE LEATHER.

BY ALAN A. CLAFLIN.

Leather tanning formerly was, and even at the present time is frequently referred to as an industry of conservative tendencies, in which progress is slow, experiments conducted with great caution, and new methods and materials

* Canadian Patent, 42,770, April 27th, 1892. English Patent, 8,469, May 4th, 1892. United States Patent, 536,019, March 19th, 1895 (see this J., 1892, 625).

and the United States (and I am not reflecting on the great contribution it was to the leather industry when I say it) like a South Sea Bubble. The Durio process is simply a tannage in a revolving drum fed through a hollow trudgeon with a strong extract liquor, or an extract liquor weak at first and increasing to high concentration as the tanning continues. While the litigation about this process shows, in general, that its essential principles had been locally anticipated, and while I believe that it was founded on certain wrong principles, yet it marks an epoch, in that it showed, in a large public way, that sole leather could be made in a few hours. The leather of the Durio process was generally not good enough to be a commercial success, although in some instances a tolerably good result was obtained by exceptionally able turners. Following this process are the many patent modifications and gradual improvements that have led up to the fairly successful processes of to-day.

In tracing this development we must first consider the reasons for the failure of the Durio process. The leather as I have seen it was objectionable because it was flat and the percentage yield small, because of its very coarse grain and bad colour, and also because of a frequent, although not consistently occurring brittleness. These faults I believe to be inherent in this process and all similar processes, because the vital and fundamental principle is not recognised that raw hide differs in physical properties from leather. An explanation may make this clearer. To a considerable degree a piece of raw hide is like a sheet of gelatine, although it has an organised structure, and from a physiological point of view has fibres, yet from a chemical standpoint the fibres, that is the vast majority of them, are identical with the surrounding cementing substance. While from their organised nature they are somewhat less soluble than the unorganised substance, they must be delicately treated until their structure is fixed more permanently. For sole leather it is necessary for thickness and solidity that the fibres be swollen and fixed in that condition before any of the harsh mechanical treatments are applied. This was not done in the Durio process, and a flat leather resulted, and one in which the yield was small, as in the flat condition the proper ratio between hide substance and tanning and filling material cannot be obtained. The grain was harshened by mechanical treatment, and by the fact that the acids, when employed to obtain some plumping, were not the proper acids. The colour was bad partly because the extracts then obtainable were not clarified, and, more important, because of the heat generated by the motion of the drum. This same heat probably accounted for the brittleness, and I imagine that in the samples of leather I have examined, made by this process which were not brittle, it was because resort had been made to some method for cooling, not described in the patent.

The recognition of the causes of these faults and their elimination has been the task of the developers of the recent more successful quick tannages. At the same time they have been aided by new and more scientific preparatory methods and by new tanning materials, with quicker penetrating properties, among which I emphasise the wood extracts, chestnut and quebracho. The cheap production of lactic acid has made available an acid that will plump without raising the grain. The mechanical improvements have been on the line of gentler treatment, and greater opportunity for the dissipation of the heat generated. In my account of an up-to-date method of quick tanning, I will endeavour to avoid detailed descriptions of unpatented mechanical contrivances in justice to their devisers, who have permitted me to examine them.

In the quick process tannery where I have had most extended opportunity to observe, packer hides are used, and, after a few hours' soaking, are ready for the lines. They remain in the lines beginning with the oldest five to seven days. As is general among the quick tanners, the lines are not sharpened with sodium sulphide or soda ash. From the lines the hides are unhaird and worked out, rinsed in a large drum with a free supply of cold water, and then put in a large octagonal slat cage with a capacity of fifty whole hides, which is

floating in a large vat containing a dilute solution of lactic acid. The weight of the hides semi-immersed in the cage, which is agitated occasionally by a workman walking on it, in a sense after the principle of a tread mill, solution is slightly warmed in winter so as to stand about 70° F.

The hides are kept in the deliming solution a six or eight hours, and in that time the cage makes three or four complete revolutions. After the deliming solution the hides are ready for the handler liquors. The handler vats are eight in number and deep enough to accommodate the whole hide suspended on the usual rocker frame operated by an eccentric with a throw of about 12 inches, and making 25 full strokes to the minute. The handlers are operated on a continuous press system, that is, the liquor flowing into the bottom of the first handler vat and then flowing from the top of that vat into the bottom of the second, and so continued through the series. The circulation is maintained by a small pump and the overflows are arranged so that each vat in turn is by the oldest or head handler, and thus no handling hides after the first tacking on the slats is necessary; they are struck through, when they are taken from the handlers. The handler liquors are bleached liquors, hemlock bark, which are made uniform by mixing and storing in large vats, when they are allowed to ferment the amount of acid calculated as acetic is over 1-2 per cent. The percentage of tannin is 3 or 4 per cent, corresponding to an 18° liquor. In the course of the handling this is lowered to from less than 2° to 5° barkon. Below 2° the tail liquors are run away, above that they are run back to the leaches or used for diluting in storage tanks. Besides the saving in tannin, the reason for the running back of the tail liquors to the leaches is that a more highly nitrogenous liquor is obtained and one which is better adapted for lactic fermentation, and having the mellow effect of an old liquor.

The hides should be struck through in eight or although ten may be allowed. The rockers are kept in motion 24 hours; in fact the whole tannery is open day and night. When taken from the handlers, the hides are allowed to drain on a horse, and then put in drums mounted on bearings, and operated by power, and half immersed in a 25° quebracho liquor. The drums have a capacity of 25 sides, and make fifteen to twenty revolutions per minute, with occasional stops to allow for cooling. In 36 to 40 hours, the sides may be said to be tanned; they are then taken from the slat drum for the operation of filling; this is done in the regular way of tanning drum. Fifty sides are put in with 1½ to 2 per side of full strength chestnut wood or chestnut bark wood extract, and milled for three or four hours. They are then taken out, allowed to hang 24 hours in a very strong liquor made from the residual extracts from the drums, and then bleached with a sulphuric acid and soda bleach. The sides are then oiled, dried in a drying chamber ventilated by mechanical draft, and rolled for the market. These operations take four or five days. Thus, we find the time required for this process to sum up as follows: Soaking, 1 day; liming, 6 days; unhairing, fleshing, and bating, 1 day; handling, 9 days; tanning and filling, 3 days; bleaching, oiling, drying and rolling, 5 days; total 25 days.

Variations of this process are as many as there are tanneries making, or experimenting with quick process tannage. Naturally, the variations are of two classes, first, the different tanning materials are used, and, second, different mechanical contrivances are employed. So I know quebracho is always a component of a quick tannage liquor. Much has been done with it alone, but its lack of filling properties necessitates the use of other and grape sugar or some other extract to give the leather weight. The combination of oak bark, quebracho, chestnut wood is very common, and a lighter colored leather is obtained than with hemlock bark. With the combination quebracho and oak bark are used in the handlers, and more acidifying done with lactic acid or lactic and acetic acids than is necessary with the unment hemlock liquor. Acetic acid alone has a tendency to raise the grain if used in sufficient quantity to bring the necessary plumpness. Sulphuric acid

used for plumping to some extent, after the method of old-fashioned acid tannage. The objection to its quick tannage is that in handler liquors, in which strength is increased so rapidly, a falling is caused in grain, while the interior of the hide remains plump. makes a leather with a brittle grain, also one hard to With quebracho and oak bark I have no record of imentation; doubtless they have been used together, he cheapness of chestnut wood or chestnut oak wood ly now brings it into combination, even though it ly be used for filling. There is a great variation quality of the chestnut extracts on the market, and election of one best adapted for the purpose is of importance. Unless it is to be used in the handlers, is seldom the case as too much colour is so obtained, ecommendation is for an extract with at least 30 per of tannin, and not over 10 or 11 per cent. non-tannin, ly clarified as possible. A colour test on sheepskin d always accompany the analysis of an extract, the tanner may know exactly what to expect. ong the mechanical arrangements, I may mention following patents:—Dupin (1), in 1897, for a tanning with automatic feed; Galbien (2) and E. H. Dewson the same year for drums of special construction; Easton (4) in 1898, covering the circulation of strong s, and Mario (5), in 1899, for attaching hides to ing and moving rolls; Bona Allen's patents in 1894, protecting arrangements for fastening the hides evolving shaft, and suspending them radially there- is noteworthy as giving excellent practical results. ent patent is that of Koenitzer (7) for the suspension of hides from the inner periphery of a drum. order to determine how near the quick process leathers ach in quality the standard leathers made by the r methods, I have made some analytical and physical minations, which I believe give a fair statement of tions as they are to-day:—

Sample.	Attrition Test.	Tensile Strength.	Moisture 105°.	Nitrogen.	Hide Substance.	Extract.	Tannin.	Non- tannin.	Sulphates.	Sugars.

om these results I think we may well consider that y the best of the quick tanned leather is nearly, or s, equal to the average leather made by the slower esses. It should be borne in mind, however, that pieces of this quick tanned leather, that is, the best e, are perhaps more carefully selected than those ed by the slower processes, although care was taken each should come from the same part of the hide. chemical analyses show that nearly as much tannin been fixed in one case as in the other. ist how much quick tanned leather is now being uced is a different question, as many tanneries are ncing both kinds, and are not over willing to give isties. My estimate is that about 600 sides per day now being tanned, and in the present condition of leather market, are being sold as rapidly as produced; t, most of the tanneries making this class of leather well sold ahead. This is a conservative estimate, if rumour is correct, 1200 sides is nearer the amount. I have chosen the smaller figure as I know of that

amount. The selling price of this leather is usually 4 or 2 cents per lb. less than the standard price, but this is variable, and the prejudice against quick tanned leather is so nearly worn away that to a large degree, such leather sells on its merits.

We may now consider on what lines and to what extent the present processes may be improved. Without hesitation, I think I may say that time can be saved in the liming, by sharpening the limes with sulphide of sodium, soda ash, or sulphate of ammonia, or by use of warm water, according to the so-called Buffalo method, instead of 5 to 7 days, 48 to 72 hours should be sufficient for depilating. Many tanners making leather in the old way avail themselves of these processes, and so far as my observations go, there is no reason why they cannot be combined with the quick methods. The Pullman process of calcium chloride and caustic soda also could be developed with advantage.

The possible use of formaldehyde, for fixing the plumpness obtained by acids, suggests a material shortening of the handler period. This product may be truly called a tanning agent, in that it fixes the fibres in an insoluble condition, and thus, by its use, it seems that in a few hours the grain and fibres might be fixed so that the delicate and graduated treatment of the handlers could be quickened or, perhaps, entirely obviated. My experiments with formaldehyde on a small scale have, however, made me a little sceptical of its value, because when it is used in sufficient quantity the fibres appear to be rendered non-absorptive, and the tannin that is worked in can be nearly all washed out again. If some method could be devised whereby the formaldehyde could be generated in small quantity in the hide itself, I believe a very practical gain would be made. My experiments with bisulphite-aldehyde compounds have not been successful. On the other hand dilute chrome solutions have seemed to be beneficial in the direction of partially tanning without

destroying the absorbent properties of the fibres. The objection to their use is that the colour of the leather is injuriously affected by the mordanting properties of the chromium.

Another question is the more general use of chestnut wood extract as a substitute for quebracho. The former is now much the cheaper, but lacks the quick penetrating power of the latter.

Eitner has stated that wood extracts have properties of quicker penetration than bark extracts, and such seems in general to be the case, but quebracho excels chestnut wood in this respect to a greater extent than chestnut wood does oak-bark extracts. I have made many experiments, and without success, to determine to what this property of quick penetration is due. A moderately pure tannin, prepared by alcohol extraction and ether precipitation, gives equally bad results whether its source be quebracho or chestnut oak. A bisulphited chestnut oak wood extract has been reported as giving quicker penetration than the ordinary extracts, yet while the bisulphited quebracho extracts are quite widely used, they are not markedly superior to the other extracts in penetrating properties. If a chestnut extract can be purified or treated so as to give quick penetrating power, it is probable that it would lose the filling properties which now recommend its use, thus making necessary the employment of two kinds of chestnut extract, one for the tanning, and the other for the filling.

One of the most important present problems in the

manufacture of quick process leather is the avoidance of loss in the bleaching process. This leather filled as it is with tannin extract, of which a considerable amount is uncombined at the time of bleaching, however much it may combine later, on keeping, yields an expensive proportion of this tannin to the soda bleach liquor. Delay before bleaching somewhat decreases the loss, and is always more or less resorted to, but loss in time is to an extent as objectionable as loss in weight. One method, of course, is to make up for loss in weight by loading with grape sugar and Epsom salts, which, to a limited extent, say $1\frac{1}{2}$ to 2 lb. to the side, is admitted in the trade as legitimate. From the wearers' standpoint loading certainly does not improve the leather, as it makes it absorb water more readily. The natural remedy is not to bleach the leather. Bleaching was adopted because it disguised leather containing considerable proportion of chestnut or hemlock and let it pass for oak, or as containing more oak than it really did. To-day no one is deceived by bleached leather, and as it is practically painted when it reaches the consumer there is no further excuse for the custom, except the theory, and it is more theory than fact, that the shoe manufacturer will pay for the light colour. If, however, bleaching must be done, a material which has strong decolorising properties should be employed and not those which depend on their tannin removing properties for their efficiency. I have had fairly successful results with permanganate of potash followed by bisulphite of soda or oxalic acid. The peroxides also give good results, but are more expensive.

In conclusion we may summarise the results of quick process tannage as follows:—Good average sole leather is now made in 30 days; this time can be shortened 2 or 3 days in the liming. Further quickening may be effected by the use of a combination process with allylhydres or inorganic compounds. Cheapening is perhaps possibly accomplished by the use of pure chestnut extracts. The mechanical arrangements are fairly good, but arrangements for cooling liquors are not yet perfected. Any great radical change is not to be expected aside from lines laid down, and business men should avoid too hasty investment in processes which will effect revolutionary changes. Great emphasis should be placed on the personal factor. With so complicated a material to deal with, keen and scientific observation, accompanied by wide practical experience, are absolute essentials to success.

That in time all sole leather will be tanned by quick processes, is to me unquestionable.

STANDARD METHODS OF ANALYSIS.

BY JOHN WHITE, F.I.C.

By standard methods of analysis, I understand to be implied methods officially prescribed and recommended by some body, duly appointed for the purpose. Every chemist possesses full liberty to adopt these methods, vary them, or improve them as he pleases. By the thoughtful such processes will be received with gratitude, they represent the collective wisdom of their originators, and are thus stamped as reliable. They are upon record from the moment of their publication, and are subject to revision. No such method is intended to represent finality.

I would emphasise this liberty of action and freedom of trial possessed by individual chemists, because it lies a reply to the argument, in my opinion, fallacious, that the adoption of standard methods must transform intelligent workers into mere animated machines for recording analytical figures, stifle originality and hinder research. I have not yet heard any proof of this assertion, nor have I found that a standard method is subjected to any less criticism than that received by a process suggested by an individual.

For an ultimate analysis of, say, starch or sugar, a standard process is wanted; the manipulative skill and chemical knowledge of the operator are the factors of importance. But, in the examination of butter, the opinion of the sample has to be based upon the results of certain empirical tests.

Again, the methods involved in the determination of the iodine value of a fat or oil, the "fineness" of a slag, the flash point of a petroleum, or the viscosity of an oil, must of necessity be standardised, otherwise the figures obtained may be meaningless. As an example of a method in every-day use requiring to be standardised, that for the determination of indigestible fibre in an oilcake or feeding meal may be quoted. In this particular estimation, the exact truth may be regarded as practically unattainable, and thus a process is required wherein the risk of error shall be reduced to a minimum.

In all such determinations, where either a constant is to be found, or where the proportion of some constituent, which does not allow of exact estimation, has to be attained as nearly as possible, it is idle to condemn standard methods of working. Surely it is desirable that concordant results should be arrived at in different laboratories, and that error of experiment should be eliminated where practicable. If the whole truth be not discovered,

s, at least, get as near to it as we may, and a od which is the result of the deliberations of a well ed committee is likely to be nearer the truth than volved by an individual.

e opponents of standard methods also urge that the t of the chemist when conducting an analysis is to at the exact truth to the best of his ability, and he can, better accomplish this by the adoption of than one analytical process, arranged so that one check the other, than by any number of repetitions a standard method. I do not see any great strength s argument; the careful and intelligent chemist will e satisfied merely by the agreement of duplicated s unless he also knows that his method is reliable; thers will continue to perpetrate their errors in any

spite of the protests of their opponents, standard ds are spreading. The International Association ather Trades' Chemists has adopted such processes hese are subject to revision at intervals. Standard ds have been formulated by a sub-committee of ew York Section for the analysis of cement and aterials. Official methods for the analysis of sers were issued by the German Manure Manufacturers iation as long ago as 1895. Methods for the estima- f arsenic in foodstuffs and brewing materials have ublished, both by a Joint Committee of the Society emical Industry and the Society of Public Analysts, a Departmental Committee appointed by the Board and Revenue, and a process for the determination e Reichert figure for butter and margarine has been ily prescribed. The Adams' process for the esti- od, and for many years the analysis of water for ry purposes has been conducted on standard lines. e analysis of food and drugs. I welcome standard ds, and hope to see them extended.

the case of food and drugs, the selection of methods e assigned to the Board of Reference recommended eated in the Report of the Select Committee on roducts Adulteration, published in 1896. In other es of technical and commercial analysis committees emists concerned in these respective branches might ointed, and here the Society of Chemical Industry ell act as the controlling force, to examine, discuss eport upon the various methods of importance used ch branch. If upon inquiry it were decided to ardis a method, no better and more fitting place blication could be found than the columns of our al. The methods should in all cases be subject to dical revision.

DISCUSSION.

J. GOLDING declared himself as distinctly opposed tandard methods. We were suffering at present oo much authority, and the evil was infecting science, ally on the Continent and in the United States. mber of men in authority meeting together seldom d, and the result was frequently a poor compromise.

S. F. BYRFORD said it considerably influenced the e public when they saw reports of analyses on any cular subject which differed considerably from one her. To obtain fixed data they must use uniform ods.

Mr. S. R. TROTMAN agreed with Mr. White's conclusion, and thought it was particularly desirable that standard methods should always be adopted where the method had to be given on which an opinion was based. It frequently happened that two chemists would arrive at the same opinion, but that their figures would differ according to the method used in the analysis. This, though quite intelligible to the chemists themselves, was not a desirable thing from the point of view of the public.

Mr. JOHN WHITE pointed out that his paper was not a plea for the introduction to this country of methods standardised in Germany. Analysis would not be so frequently discredited if standard methods were adopted, nor would it then be necessary to attach to the analysed results a description of the process by which they were obtained.

Meeting held at Nottingham, on Wednesday, March 22nd, 1905.

MR. J. T. WOOD IN THE CHAIR.

COMMERCIAL AMYL ALCOHOL.

BY S. F. BYRFORD.

Since the introduction of the Lefman Beam method of estimating fat in milk, I have tested many samples of amylie alcohol, and compared with standard processes have obtained results, not differing by more than 0.3 per cent. as fat.

A recent sample purchased as amylie alcohol has presented such abnormal results as to indicate the necessity of standardising each batch of alcohol.

The sample mixed with an equal volume of hydrochloric acid, soon separated, and did not become darker on keeping.

Milks tested with ordinary amylie alcohol gave:—

4.4 per cent. fat but 7.1 per cent. with the abnormal alcohol.			
3.4	"	6.1	"
3.9	"	6.7	"

showing a constant excess of 2.7.

In a blank experiment without any milk 3 c.c. of a mixture of equal parts of the alcohol and hydrochloric acid diluted with sulphuric acid 1 in 4, and 9 c.c. strong sulphuric acid after rotating gave 3.7 c.c. of a straw-coloured liquid.

Three c.c. of hydrochloric acid and alcohol and 15 c.c. sulphuric acid strong, and bottle filled up sulphuric acid 1 in 4, gave 6.5 c.c. separated liquid, 5.5 c.c. yellowish upper portion, 1 c.c. colourless lower portion.

Fifty c.c. of the alcohol mixed with 50 c.c. of sulphuric acid 1 in 4 and 50 c.c. strong sulphuric acid, added, gave no oily layer, but after standing 24 hours separated into two layers—an upper dark blackish-brown portion and a lower portion about 70 c.c. of sherry-coloured liquor smelling of amylie alcohol.

The abnormal sample presented the following characters:—

Temperature.	Volume of Distillate.	Sp. Gr. of Distillate at 60° F.	No. of c.c. of Normal Alcoholic NaHO required to neutralise 5 c.c. of Distillate.	
Up to 120° C.	6.0 c.c.	—	0.55 c.c.	Strong amyl odour.
130	5.5	—	1.7	Strong amyl odour.
145	3.5	0.831	0.8	Faint pear odour.
155	12.0	0.836	3.5	Sweetish pear odour.
170	8.7	0.851	6.3	Heavy odour inducing flushing rush of blood to head.
150	8.0	0.870	10.5 c.c.	Cheesy odour.
190	16.0	0.8796	11.2 c.c.	Stuffy odour.
200	4.3	0.874	5.45 c.c.	Oily cheesy odour.
in rector 4.0		—	2.6 c.c.	Rancid oily odour.
5. of original sample of alcohol			4.8 c.c.	

The later distillates had an extremely persistent and disagreeable putrid cheesy odour.

Mixtures of 1.5 c.c. of the various distillates and 1.5 c.c. of hydrochloric acid were used to estimate the fat in milk containing 2.9 per cent. fat.

Distillate obtained :—

Above 130 up to 145° C.	gave 4.2 per cent. of fat-like liquid.
155 " "	5.3 " "
170 " "	6.8 " "
After rotating in Leftman Beam bottles	
Above 130 up to 180° C.	gave 10.6 per cent. of clear white liquid ;
	1.5 milky liquid.
(0.75 c.c. distillate obtained between 170° C. and 180° C.)	gave 2.8 c.c. clear
and	5.3 c.c. "
(0.75 c.c. hydrochloric acid	1.2 straw colour
0.75 c.c. distillate from 180° C. up to 190° C. gave	1.3 pinkish colour.
and	6.0 c.c. clear.
0.75 c.c. hydrochloric acid	13.0 c.c. milky white.

Beyond the fact that the amyl alcohol had been in store for some time the vendors could furnish no clue.

Yorkshire Section.

Meeting held at Bradford, on Monday, March 20th, 1905.

MR. G. W. SLATTER IN THE CHAIR.

"NOTES ON WATER SOFTENING."

BY WALTER M. GARDNER AND L. L. LLOYD, PH.D.

(A Contribution from the Department of Chemistry and Dyeing of the Bradford Technical College.)

The advantages to be gained by the use of soft water in steam raising and for most manufacturing operations, are now generally recognised. The point of most importance in connection with a water supply for household purposes is its freedom from organic impurity. For works purposes this is of very minor importance, but in many works the town supply is used, under the impression that it is the best procurable. This is by no means necessarily the case, either as regards quality or price. The cost of towns' water to manufacturers varies between 4d. and 1s. per 1000 gallons, and usually the latter figure is far above the interest on the cost of sinking a well and pumping, even if a subsequent softening process is necessary. Probably the recognition of this fact is the main cause of the recent great extension in the number of private water supplies in certain districts. Curiously enough, those towns' supplies which are the least suitable for works' purposes are often the most costly, and in such cases, a double advantage is possible by using private sources.

No hard and fast rule can be laid down with regard to the desirability of softening a water. From the point of view of steam raising, this will depend not only on the nature of the water, but upon the type of boiler used, the working pressure, circulation, &c. It should be clearly recognised that the cost of the water before it enters the boiler is in any case small compared with the cost of converting it into steam. Taking as a basis that 1 lb. of coal at 8s. per ton burnt in the furnace of the boiler, will convert 9 lb. of water into steam, the cost of evaporating 1000 galls. of water would be 4s., whereas the cost of the water, even including softening, should not exceed 6d. per 1000 galls. As an average statement, it is also probably well within the mark to say that the use of a water of 20° hardness will cause a loss of 15 to 20 per cent. in fuel, that is to say, the decrease in the efficiency of the boiler due to scale formation, more frequent blowing off, increased repairs, &c., will be about 20 per cent. This means an increase in the cost of evaporation of about 1s. per 1000 galls., whereas the cost of softening including interest on plant, should not, in an extreme case, exceed 3d. per 1000 galls. From the point of view of steam raising, the softening of water is thus well worth consider-

ation, to all interested in power production of any magnitude.

In the case of processes in which soap is used, soft water is very essential. One thousand gallons of a water of 20° hardness will destroy at least 12 lb. of ordinary soap. Thus, apart from the inferiority of the result due to the presence of calcium and magnesium soaps, the increased cost of the process incurred by the hardness of the water would, in the supposed case, be 2s. 6d. for each 1000 galls. of water used; and this is still out of proportion to the cost of softening than in the case of steam raising. Soft water is thus essential for laundries, for wool washing, and wherever large quantities of soap are used.

For general dyeing purposes, the permanent hardness of a water is of small importance compared with temporary hardness. The removal of any considerable amount of permanent hardness, moreover, always in a certain degree of alkalinity—a very objectionable feature in water used in a dyehouse. Taking into account the requirements of the dyer only, it is, therefore, preferable to confine the softening process to the removal of temporary hardness, but since steam raising, and usually washing, are also carried on in the same works, regard must of course be paid to the general requirements in advising as to the best softening process to employ in any particular case.

The use to which the water is to be put should influence the decision as to whether a water can be advantageously softened, and should determine the process of the softening process recommended.

The actual results obtained by the softening process depend upon a complex set of conditions, the chief of which are probably the following :—

1. The degree of hardness of the water.
2. The amount of magnesium salts present.
3. The amount of neutral salts present.
4. The method and apparatus used in carrying out the process.

A good deal of attention has latterly been paid to the influence of magnesium salts in water softening, but the effect of the presence of neutral salts and the influence of the apparatus employed in softening, have hardly received due recognition by chemists.

Effect of Neutral Salts.

Examination of a large number of water samples from all parts of the country, has led us to the conclusion that, on an average, six waters in ten may be expected to contain a fairly large quantity of neutral salts, chiefly sodium sulphate. Far too little attention is paid to the influence of these bodies, not only in water softening, but in the action of the water in subsequent use, and we have been led to attribute many irregularities in results to this cause. The presence of neutral salts in considerable quantity, is indicated by a great difference between the amount of total inorganic solids, and the total hardness, and in such cases we have found time after time, that the softening process cannot be pushed so far without increasing alkalinity as is possible in the absence of neutral salts. This is, of course, not surprising if the equation—

is partially reversible, and this we have found to be the case.

The removal of calcium permanent hardness by means of sodium carbonate or magnesium permanent hardness by means of lime and soda, results of course, in an increase in the amount of mineral solids in the water, since 142 parts of sodium sulphate are produced by the removal of 136 parts of calcium sulphate or 120 parts of magnesium sulphate. The softening of a water of 10° permanent hardness, will thus generally result in the presence in the soft water of about 11 grains of sodium sulphate per gallon. This amount is quite sufficient to exert a deleterious effect in such processes as washing off after dyeing acid colours; and we have known this more than once to be the cause of serious trouble in the use of a soft water. It may here be pointed out that the use of burnt

xide as a precipitating agent does not result in the precipitation of soluble sulphates, and this is perhaps its advantage. We have further experiments in progress regard to the influence of neutral salts in water softening and water softening.

Influence of the Apparatus.

The influence of the method and of the apparatus used, the degree of softening attainable, is largely concerned with two variables, *viz.*, the time during which the reaction is allowed to proceed before removal of the precipitate, the temperature at which the process is conducted. The use of a suitable apparatus it is frequently practicable to utilise waste steam, and thus raise the temperature of the reacting chamber. Another plan which may be adopted, is to run the water through a condenser before giving it to the softening plant. In any case, raising the temperature greatly facilitates the reaction.

As regards the time factor it is not to be expected that reactions carried out in such dilute solutions as in water softening, will be completed very rapidly, other things being equal, that apparatus will give the best result which allows of the longest time of contact before the deposit is removed. This, of course, largely determines the output of a plant of a given size, and it is frequently the case that with a view to economy of installation, an apparatus of too small a size is put up, in order to obtain the necessary amount of water, the plant is then worked at such a rate of flow that the time of contact is not given, with the result, that the necessary amount of further deposit is produced in the storage tank or in the boiler.

Another point having an important influence on complete and rapid reaction, is to ensure a sufficient degaeration of the water after mixing with the reagent. In experiments we have carried out on a large scale, we end to show that the reactions are more complete when the apparatus is under pressure.

In the technical softening of water the treatment is sometimes confined to the removal of temporary hardness by action with lime. This case is perfectly simple if the water contains calcium salts only, the amount of lime hydroxide required being of course equivalent to calcium bicarbonate, plus the free carbon dioxide.

The reaction is also quantitative in the case of solution of magnesium bicarbonate as shown in Table I, but in this case a double quantity of calcium hydroxide is necessary, as the magnesium should be precipitated as a hydroxide and not as carbonate. If magnesium chloride or sulphate is present, the total magnesium must be taken into account. In this case Pfeifer and Wartha (*Zeits. angew. Chemie*, 1902, 198) as stated by H. R. Procter (this J. 1904, 8) gives the lime required as $111 + 11m - 11p$, when 1 = temporary hardness, p = permanent hardness, and m = magnesium hardness. This formula is, however, incorrect for the case in question, as when lime is added to mixtures of calcium bicarbonate and magnesium sulphate, the temporary hardness is not completely removed until sufficient lime is added to react with the total magnesium salts as well as with the calcium bicarbonate. This is shown in Table II.

Considerable experience in the use of the Pfeifer and Wartha formulae for determining the amounts of reagents to use in water softening has led us to the conclusion that although they give approximate results in many cases, they cannot be relied on when dealing with waters containing much neutral salts. It is indeed, not to be expected that the results of reactions carried out in such great dilution, and with such complex bodies as occur in water softening, can be readily calculated by means of a simple formula; and we have been led to support the view of those chemists who prefer to determine the amount of lime and soda by direct experiment. We proceed as follows:—

Determination of Lime Factor.

210 c.c. of the sample is transferred to a stoppered cylinder, and lime water of a known strength is added in considerable excess. The cylinder is kept stoppered and shaken during two hours, the precipitate being then allowed to settle, or being removed by filtration in the case of magnesium waters which do not readily settle. Seventy c.c. is pipetted off and titrated with $N/10$ hydrochloric acid, using first phenol phthalein, and then methyl orange as indicator. The difference between the two titrations is probably a measure of the calcium and magnesium carbonates still in solution and this is deducted from the figure obtained in the phenolphthalein titration. The result then gives the amount

of lime in excess, and the figure thus obtained is more accurate than by a simple titration. We have found in practice that the amount of lime determined in this manner works out quite satisfactorily when applied on a large scale, and in the case of several installations of softening plants, practically no subsequent adjustment has been necessary.

Determination of Soda Factor.

70 c.c. of the sample is placed in a platinum dish, and an excess of N/10 sodium carbonate is added. The solution is evaporated nearly to dryness, and then somewhat diluted, and the precipitate washed with air free

water. The excess of sodium carbonate in the is then found by titration with N/10 sulphuric acid. This also gives the permanent hardness of the water in the absence of sodium carbonate in the original water. If this is present, as is not infrequently the case, it is determined as follows:—70 c.c. of the water is evaporated to dryness in a platinum dish on the water bath. The residue is treated with a small quantity of water from carbon dioxide, filtered, and the filtrate treated with N/50 sulphuric acid. The amount of acid required to neutralise the alkalinity thus found is reduced to N/10 acid and is then deducted in estimating the permanent hardness.

In Nos. 1, 3 and 5, the amount of Lime added has been calculated from Pfeifer's Formula $5.6(T.H. + MgH.)$. In Nos. 2, 4 and 6, the amount of Lime added was the "Lime Factor" found by experiment.

The results of experiments carried out on these lines are shown in Tables I., II., IIIA., and IIIB., compared in some cases with results obtained by Pfeifer's formula. It is found that in some waters the lime factor obtained by direct experiment is less, and in other cases is greater than the amount calculated by Pfeifer's formula. All the softening experiments were carried out with 210 c.c. of

water shaken in cylinders with the reagents during 24 hours, then filtered and analysed. The filtered water did not further precipitate on standing 24 hours. In some cases better results were obtained by adding the lime and soda in two separate operations, this being in accordance with the results in Table IIIB.

	C	do.	do.	do.	29.7	55	5.0	—	—

In analyses A the amount of Lime has been calculated by Pfeifer's formula.

In analyses B the amount of Lime has been found experimentally, as in Tables I. and II. and Lime and Soda being added to the water simultaneously.

In analyses C the Lime has been added as in B, the liquid shaken 2 hours, filtered and the soda then added.

In analyses D, the water has been treated with lime only as in B.

When the above method is adopted, the analysis necessary in connection with water softening is extremely simple, comprising merely the determination of the lime and soda required. When a direct determination of hardness is required, we employ the ordinary Hehner process for the temporary hardness, preferring methyl orange or laemoid as indicator to alizarin, as recommended by Pfeifer, because in the latter case it is necessary to boil, and this introduces errors due to secondary reactions.

In the estimation of permanent hardness we have found no advantage in the use of a mixture of sodium

carbonate and sodium hydroxide as proposed by Pfeifer, since the magnesium carbonate is totally insoluble in excess of sodium carbonate. For the estimation of magnesium salts, Pfeifer's method as described by Pfeifer has been adopted.

Reference may finally be made to the use of barium hydroxide as a reagent in water softening. This has recently been placed on the market as a solid product containing about 60 per cent. of barium oxide. Experiments with this substance have not been very exhaustive, but we have come to the conclusion that at its present price it can only be used in very small

The amount employed must never exceed the amount of the temporary hardness due to calcium carbonate or half the temporary hardness due to magnesium carbonate. In the case of magnesium sulphate, barium hydroxide may be added until the whole precipitated, as both products, barium sulphate and calcium hydroxide are insoluble. Addition of lime in this case required for removal of temporary hardness shown in Table IV., No. 6). In the presence of lime sulphate, sodium hydroxide is of course formed, or this reason baryta cannot be used to diminish total solids in water so far as they are due to sodium sulphate. The solubility of barium carbonate is variously given in books as 1 part in 4000, 12,000, 14,000, 47,000, 64,000 of cold water. One experimental result

any experience of softening water where calcium sulphate was the chief cause of trouble, and where it was difficult to bring about deposition of precipitate. He did not agree with Mr. Richardson that carbonate of soda was the best thing to recommend, but would use in addition caustic soda and seaweed or starch, and possibly sugar or gummy matters, which caused a softer scale to be formed.

Mr. W. M. GARDNER said he had not found people disinclined to adopt water softening apparatus. He thought some tanning material (e.g., catechu) mixed with soda ash of use in the treatment of hard waters in steam boilers. Plentiful agitation was necessary in cases where sulphate of lime had to be dealt with, as this caused more

that it possesses considerable solubility, probably 1 in 12,000, and as the barium compounds are not to be poisonous, barium hydroxide must be used with great caution in the treatment of drinking water. The amount used is carefully regulated, however, to avoid the possibility of the presence of barium carbonate, trace of barium remains in solution.

DISCUSSION.

G. W. SLATTER said temperature and the length of action were important in water softening, 6 to 12 hours being usually required in a continuous form apparatus. The Archbutt-Deely apparatus took only 10 minutes. Caustic baryta was not a suitable softening agent owing to its poisonous properties and its cost.

T. FAIRLEY thought barium hydrate was of doubtful benefit when used to soften water. The Archbutt process saved time and expense as the blowing in and the mixing of the old precipitate with the new and the latter to deposit more quickly. For the reason deep tanks were preferable, because the precipitate from the upper layers rapidly carried the lower layers, and thus produced a much more uniform settling.

F. W. RICHARDSON said manufacturers would not go to the expense of softening water outside the boiler, previous to use. He had found best soda ash the useful reagent to advise to put in boilers.

W. McD. MACKEY understood that good results were obtained when water was softened under pressure. Barium hydrate was suitable for bad waters containing amounts of sodium sulphate, but he had always tried to recommend its use.

F. W. BRANSON said that discrepancies mentioned by Mr. Gardner as to the solubility of barium carbonate were no doubt due to the varying amounts of carbonic acid gas present in the waters used for the experiments.

W. RUSHBY said he believed in softening the water outside the boilers. He asked if Mr. Gardner had

rapid deposition of the carbonate of lime precipitate. He warned manufacturers against using sesquicarbonate of soda in the softening of water in mistake for the ordinary carbonate (or soda ash).

Meeting held at Bradford, on Monday, March 20th, 1905.

MR. G. W. SLATTER IN THE CHAIR.

THE PREPARATION OF STANDARD SOLUTIONS OF SULPHURIC ACID.

BY B. NORTH, A.R.C.S.C. (LOND.), F.C.S., AND W. BLAKEY.

(A Communication from the Department of Chemistry and Dyeing of the Bradford Technical College.)

A process in frequent use in laboratories for the preparation of a standard acid, and the one generally recommended in text-books, is the method of standardising with sodium carbonate, prepared by igniting the bicarbonate.

During the last 12 years many other methods have been suggested. In 1892, Bornträger (Z. angew. Chem., 1892, 294) proposed the use of potassium hydrogen tartrate, which by ignition is converted into the carbonate. In 1893, Rimbaud (Ber., 26, 171) suggested the use of borax as an agent for obtaining a standard acid, and this has been supported by Salzer (Zeits. anal. Chem., 1894, 32, 529), Buchanan (this J., 1894, 1093), Perman and John (Chem. News, 1895, 71, 296). Moody (Jour. Chem. Soc., 1898, 658) described a method of obtaining a standard acid by weighing the amount of hydrochloric acid gas absorbed in water, but the arrangement of apparatus is hardly suitable for technical work. A similar method was suggested by Higgins in 1900 (this J., 1900, 958). Sørensen, in 1899 (Revue de Chim. Industr., 9, 107, 304), suggested the use of sodium oxalate, which gives, he says, pure sodium carbonate by ignition. Marshall, in 1899, and again in 1902, (this J., 1900, 4 and 1902, 1598), published tables of specific gravities of sulphuric acid. Recently (this J.,

1905, 178) Worden and Motion have given tables of specific gravities of sulphuric and hydrochloric acids between the limits of N 10 and N 1 solutions, and Kaster and Munch (Ber., 1905, 38, 150—152) have also recently published a table of specific gravities of hydrochloric acid. Kohn, in 1900 (this J., 1900, 962) suggested the electrolysis of pure copper sulphate as a means of making standard sulphuric acid, the amount of acid in the electrolysed solution being found from the weight of copper deposited. This method has, however, been criticised by Danvé (Jour. Pharm. Chim., 1902, 16 [2], 65), who maintained that the deposited copper is always mixed with cuprous oxide.

Substances such as borax containing several molecules of water are hardly reliable, especially when these bodies have to be dried in the air, and all methods which depend on the ignition of salts for the production of dry sodium carbonate must fail in the preparation of an accurate acid, owing to the formation of hydroxide. Rimbach, in 1893 (Ber., 26, 171), seems to have first noticed this fact, and states that ignited sodium bicarbonate is liable to contain hydroxide, though Higgins (this J., 1900, 958) first definitely stated that sodium hydroxide was formed by the ignition of bicarbonate even at temperatures as low as 170° C. Gardner, however, in 1899, definitely proved the formation of hydroxide under these conditions, and early in that year wrote to some of the chief manufacturers of pure chemicals asking to be supplied with a specimen of dry sodium carbonate, free from hydroxide; these firms replying that to their surprise they had found that they were unable to accede to his request. Some two years ago, we independently observed the formation of sodium hydroxide. Supposed pure sodium carbonate had been prepared by the ignition of bicarbonate, but when a solution was titrated with acid, using phenolphthalein and Methyl Orange, the results always indicated the presence of hydroxide, and by the silver nitrate test this observation was confirmed. We have obtained similar results by the ignition of potassium bicarbonate and bitartrate, and with sodium bicarbonate have noticed the formation of hydroxide at temperatures as low as 120° C. At lower temperatures, the bicarbonate is not completely decomposed. One of us, in conjunction with Prof. Gardner, is continuing the work on the amounts of hydroxide formed at various temperatures.)

As it was found impossible to obtain pure, dry sodium carbonate, an attempt was made to prepare pure bicarbonate for the purpose of standardising acid. A sample of bicarbonate was carefully tested and found to contain a small quantity of sodium chloride as an impurity, but this was easily removed by washing with water. The washed bicarbonate, when tested with phenolphthalein, always showed a purple coloration, indicating the presence of the normal carbonate. Sodium carbonate is soluble in a saturated solution of common salt, whereas the bicarbonate is insoluble, and in this way the whole of the normal carbonate was removed, but in the subsequent washing, to free the bicarbonate from salt, it was found that the bicarbonate was slowly dissociating and again forming the normal carbonate. This is in accordance with results which we have observed that sodium bicarbonate in solution slowly dissociates with the formation of normal carbonate when the solution is freely exposed to the air. Various methods were employed with the object of removing the normal carbonate or of converting it into bicarbonate, and we ultimately succeeded in obtaining the perfectly pure and dry bicarbonate in the following manner:—

About 400 grms. of bicarbonate are washed in a large funnel with distilled water using a filter pump, until the wash water gives no reaction for chloride, and until the bicarbonate, when tested qualitatively, is found to be pure with the exception of the presence of the normal carbonate. The bicarbonate is then dried in the air on porous plates, afterwards powdered, and placed in a moist atmosphere of carbon dioxide for several hours, until it gives no reaction with phenolphthalein. It is preferable to expose only a thin layer of bicarbonate to the action of the gas, the method we adopt being to place the bicarbonate in a shallow dish over a second containing water, the two being placed in a Hempel's desiccator, or in a

bell-jar standing on a glass plate. The desiccator, exhausted by means of a water pump, and carbon dioxide washed with water, is allowed to slowly enter the desiccator, the atmosphere of moist gas being maintained in connection with a Kipp's apparatus during the absence of gas. When free from the normal carbonate, the bicarbonate is transferred to a desiccator containing sulphuric acid, though with a large quantity it is preferable the substance in a vacuum desiccator containing phosphoric anhydride. Several different specimens prepared in this way have given identical results when against the same acid, and one specimen had been for six months *in vacuo* over phosphoric anhydride, proof that the dry bicarbonate is perfectly stable in the absence of moisture. We have observed that the bicarbonate is not stable in presence of moisture, but bicarbonate is saturated with carbon dioxide and immediately, it is impossible to detect the formation of any normal carbonate. To ascertain whether a specimen is free from carbonate, a small quantity moistened with phenolphthalein, and a few drops of water added; the smallest trace of carbonate is detected in this way. Every specimen of commercial bicarbonate, although sold as "pure," which we tested, has yielded the reaction for carbonate, and we are inclined to think that the pure and dry bicarbonate we have obtained has never before been prepared in a state of purity.

The pure bicarbonate may be used as a means of preparing an accurate standard acid; a quantity is weighed out, dissolved in water, and titrated with acid. A standard solution of bicarbonate may be prepared to make several titrations, the indicator used being Methyl Orange.* Dissociation during solution formation of the normal carbonate, is of no consequence. Making use of the bicarbonate, the results given in the table show that the factors of different specimens of

TABLE I.
Standardisation of Sulphuric Acid.

acid are in close agreement with those obtained by the gravimetric method of standardising sulphuric acid. First we failed to obtain gravimetric results which were in perfect agreement, the factors being invariably low, and this was found to be due to the formation of barium sulphide by the partial reduction of the sulphate. Even when the precipitate and ash are ignited separately, our results show the necessity of moistening the precipitate and ash with one or two drops of hydrochloric acid and sulphuric acid, in order to convert any barium sulphide, formed by the ignition, into barium sulphate. We draw attention to this point, as, although it is mentioned in one or two text-books, it is omitted in the majority of analytical works.

The various specimens of normal acid were prepared by

*The strength of the Methyl Orange solution is 1 g. in 100 c.c. of the solvent being methylated spirit and water. This indicator, it is important to use only the smallest quantity of the indicator so as to give a very pale yellow colour, and to continue the addition of acid till the tint changes to orange and not to pink. At the end of the reaction, the addition of another drop of acid should produce a pink colour.

all's method, the specific gravity of strong sulphuric acid diluted with about half its bulk of water being first determined, and a known weight was then diluted to 100 cc. The factors as obtained by this method are generally low. We have made no systematic examination of this method, the acid used being the ordinary sulphuric acid, but our results show that under the conditions the method cannot be considered a reliable one. Sutton, in his work on volumetric analysis, states that he has shown the method to be an extremely accurate one by comparison with ignited sodium bicarbonate, the latter cannot be made to yield accurate results, as that one error has merely been tested against another. By taking the specific gravities of the normal acid recommended by Worden and Motion in a recent issue of this Journal, lower factors still were obtained, as shown in Table I.

The usual method of standardising acid, using carbonate of soda from the purified bicarbonate by ignition, has been tested against this method of standardising purified bicarbonate. The ignition was performed in a tinned dish at a dull red heat so as not to fuse the dish, which was heated until constant in weight, and the residue was pure sodium carbonate, the factors of the acids were obtained, but in all cases these were 1 per cent. too low as shown in Table I, and indicate the presence of hydroxide. Other results in the absorption of moisture by the residue raised the factor. Similar results were obtained using pure bicarbonate in porcelain dishes, but the results were more variable and in all cases it was observed that the glaze of the porcelain was attacked by the alkali, and loss in weight when purified bicarbonate is ignited in a tinned dish is always greater than one would expect from theoretical considerations, though the errors of the method should be on the other side. By using carefully dehydrated with lime and sodium, we have been able to extract caustic soda from ignited sodium carbonate.

If, however, the factors obtained with so-called pure bicarbonate, as sold, the different specimens being

TABLE II.

Factors of Bicarbonate, as sold, Compared with Pure Bicarbonate.

Bicarb. No. 1.	Bicarb. No. 2.	Bicarb. No. 3.	Bicarb. No. 4.	Pure Bicarb.
1.039	1.036	1.042	1.043	1.051
1.084	1.082	1.092	1.088	1.094

obtained from widely different sources, and these factors compared with those obtained from purified bicarbonate.

The specimens on the market, it has been found, are very dry, and the errors in the factors, 1 per cent. on the average, are due to the presence of normal carbonate. Other impurities would give a different factor.

Purified bicarbonate, as sold, has also been compared with ordinary bicarbonate subsequently dried in a vacuum or with phosphoric anhydride, and also with the bicarbonate after saturating with moisture and carbon dioxide, the specimen being afterwards dried in a vacuum desiccator with phosphoric anhydride. In all cases the bicarbonate increased in weight about 1 per cent. by saturating with moisture and carbon dioxide, and this method may therefore be made use of in determining the percentage of normal carbonate in samples of bicarbonate. The results are shown in the following table:—

TABLE III.

Ordinary "Pure" Bicarbonate.	Washed and Dried Bicarbonate.	Purified and Dried Bicarbonate.
1.039	1.032	1.051
1.084	1.077	1.095

The decrease in the factor by washing is accounted for by the increase in the amount of carbonate, produced by dissociation of the bicarbonate.

The use of dry purified bicarbonate possesses many advantages over other substances for preparing a standard acid. It is easily got in a state of purity, is perfectly stable in a dry atmosphere or in a closely stoppered bottle, is non-hygroscopic, and, as the atomic weights of the constituent elements have been determined with great accuracy, it therefore readily lends itself to the production of an extremely accurate standard acid.

For technical work it is quite as accurate to standardise with the commercial bicarbonate as with ignited bicarbonate, and the tedious process of ignition may thus be avoided, but, if a correction of +0.01 be made in the factor obtained with commercial bicarbonate in standardising an approximately normal acid, a value will be obtained which is sufficiently near for all commercial purposes. It is advisable, however, in such a case to allow a weighed quantity to remain overnight in a sulphuric acid desiccator, in order to ascertain whether the sample is dry.

As it is possible, by the method which we have described, to prepare 100 or 200 grms. of the purified bicarbonate in a few days with little attention to the process, we recommend the preparation of the pure compound, or, in any case, the preparation of a small quantity from which the alkalinity of a larger specimen of ordinary bicarbonate may be determined, the latter being then kept specially for the standardisation of acid.

DISCUSSION.

Mr. T. FAIRLEY said Fresenius' method of igniting filter papers in a platinum wire coil separately from the precipitate would prevent reduction of barium sulphate. He could not see how this took place if the platinum vessel used was in an oxidising atmosphere during the ignition. A disadvantage of the gravimetric standardisation was the tendency barium sulphate had to carry down other salts with it. Assuming barium chloride to be used as the precipitant the minimum quantity necessary to precipitate the sulphuric acid should be used. After weighing, the precipitated sulphate should be boiled with dilute nitric acid, dried and reweighed, the solution being tested for chlorides.

Mr. W. McD. MACKEY advised the use of sodium bicarbonate as the standard for very accurate work. The barium chloride precipitation was so handy that technical chemists generally employed it, but it should be remembered that in sulphuric acid containing hydrochloric acid the barium chloride method of standardising would be inaccurate.

Industrial Alcohol.

REPORT OF THE DEPARTMENTAL COMMITTEE ON INDUSTRIAL ALCOHOL TO THE CHANCELLOR OF THE EXCHEQUER.

Presented to Parliament, 11th April, 1905; issued 15th April, 1905.

By permission of the Controller of His Majesty's Stationery Office.

TERMS OF REFERENCE.

To inquire into the existing facilities for the use, without payment of duty, of spirits in arts and manufactures, and in particular into the operation of Section 8 of the Finance Act, 1902, and to report whether the powers conferred upon the Commissioners of Inland Revenue by this section permit of adequate facilities being given for the use of spirits in manufactures and in the production of motive power, or whether further facilities are required; and if it should appear to the Committee that the present facilities are inadequate, to advise the further measures to be adopted, without prejudice to the safety of the revenue derived from spirits, and with due regard to the interests of the producers of spirits in the United Kingdom.

Report.

1. We have the honour to submit to you the following report of our proceedings and conclusions in connection with the inquiry, which, in August last, you invited us to undertake into the question of facilities for the use of spirit in arts and manufactures.

INTRODUCTORY REMARKS.

2. In interpreting the terms of reference, we have considered that the main objects of our inquiry were to ascertain the extent to which alcohol is, or might be, employed in arts and manufactures; or in the production of heat, light, or motive power; and to determine conditions of greatest freedom that could be accorded to its use for those purposes, consistently with adequate safety to the revenue derived from spirit as an article of human consumption.

3. We have, therefore, confined our attention almost exclusively to these points: and have not attempted to deal fully with allied questions, such as possible changes in the methods of producing spirit, or in the materials from which it may be obtained, or such as the actual or possible sources of supply. These questions, important as they are in themselves, seemed to us somewhat remote from the purpose immediately in view; and their investigation would have unduly enlarged and prolonged our labours.

4. We did, however, for special reasons, take some evidence on the question of the production of spirit from potatoes: enough to satisfy us that in the present agricultural conditions of this country it would not be possible to found a profitable industry on the employment of potatoes as a material for distillation.

5. In order to obtain evidence, we addressed ourselves to the Association of Chambers of Commerce of the United Kingdom, and to the Chambers of Commerce of London, Liverpool, Manchester and Birmingham; and the majority of witnesses examined by us were gentlemen selected for us by those bodies, as representatives competent to speak on behalf of the several industries in which alcohol is, or might be, employed. Of the rest, some came at their own request, while others came on our direct invitation. In addition to oral evidence, much information was laid before us in the form of memoranda prepared for us by the Board of Inland Revenue, in regard to the regulations in this and other countries governing the use of spirit for industrial purposes, as to the quantities of spirit so used, and as to the Rules and Regulations laid down by the Board of Inland Revenue under the Act of 1902. These memoranda are printed as appendices to the evidence. Lastly, as in the evidence of certain of the witnesses who came before us much stress was laid upon the system and regulations established in Germany in connection with the industrial use of alcohol, we felt it was very desirable to procure information at first hand upon that subject; and we accordingly obtained your authority to send a deputation to Germany for that purpose. The report of this sub-committee is annexed in immediate continuation of this report.

CONDITIONS GOVERNING THE USE OF SPIRIT FOR INDUSTRIAL PURPOSES.

6. The use of methylated (denatured) spirit duty-free was first authorised in 1855 by the Act, 18 & 19 Vict., c. 38. The present law on the subject is contained in the Spirits Act, 1880, as amended by the Customs and Inland Revenue Act, 1890, and Section 8 of the Finance Act, 1902.

7. The practice resulting from the law has been as follows:—

Up to the year 1855, spirit could not be used duty-free by the public under any circumstances. From 1855 to 1861 it could be used duty-free for manufacturing purposes only, if methylated according to the prescribed process.

From 1861 to 1891 spirit could be used duty-free for any purpose other than consumption directly or indirectly as a beverage, or internally as a medicine, provided it was mixed with wood-naphtha, to the extent of one-ninth of its volume. But, if used in large quantities, as for manufacturing purposes, it

could not be purchased from a retailer of medicinal spirit, but only from a methylator, and the subject to Excise supervision.

From 1891 to 1902, the use of this kind of methylated spirit (which came to be described as "or methylated spirit") was confined to manufacturing purposes, subject to the same conditions as while for general purposes a spirit, consisting of spirit with an addition of 0.375 per cent. of mineral naphtha (petroleum), and known as "mineralised" methylated spirit, was brought into use. It is only in this spirit that retailers are permitted to deal.

Since 1902, the two kinds of methylated spirit continued to be used as before. But an alteration to their use has been opened to manufacture which spirits may be employed after being subjected to some special process of denaturing, applicable to that particular industry, or possibly even to other states, should circumstances be held by the Board of Inland Revenue so to require.

8. Advantage has been taken of the Act of 1902 by a certain number of manufacturers. But, in examining witnesses who have come before us, we have been unable to find in some quarters a very inadequate acquaintance with its provisions, and much failure to appreciate its significance; and we are disposed to think that the beneficial effects of the Act have, on this account, been less widely diffused than they might have been. It is reasonably to be expected that, as a result of this inquiry, enterprising traders will more largely avail themselves of the provisions of this Act.

HINDRANCES TO THE USE OF SPIRIT FOR INDUSTRIAL PURPOSES IN THE UNITED KINGDOM.

9. The "ordinary" methylated spirit is open to many objections as a material or instrument of manufacture. In a few cases it is unsuitable by reason either of its chemical properties or of the smell of the wood-naphtha it contains. But even where its character is not objectionable, it is still always open to this disadvantage, that it is somewhat heavily enhanced in cost as compared with pure spirit. For not only does the wood-naphtha added to it must be present to the extent of 10 per cent., but it also tends to double the price of the equivalent quantity of pure spirit, but now and again it tends to make the methylated spirit more efficient for the purpose in view than it would be if it were pure.

10. It was to meet these objections that legislation was undertaken in 1902; and, so far as they are concerned, we consider that Section 8 of the Finance Act of 1902 does all that is possible in respect of the character of the spirit. For it has entirely removed all difficulty in the way of procuring a spirit suitable in character for any industrial purpose. It has also to some extent mitigated the objection on the score of cost, inasmuch as the various processes of denaturing authorised by the Board of Inland Revenue are commonly less expensive to the manufacturer than is the case with "ordinary" methylated spirit. On the other hand, the cost of these processes is added to the charges for Excise supervision.

11. But the cost of denaturing touches a point which brings us back to the question of the price of the spirit used for industrial purposes. An influence on price, even more important than at an earlier stage of production of the spirit, lies in the conditions under which spirit can alone be manufactured in this country. The duty on spirit as a beverage in the United Kingdom is very heavy, and imposing this duty it is essential to the protection of the revenue to impose on the manufacture of spirit such restraints as may be necessary to prevent any escape of payment of duty; and a consequence of these restraints must be to cause an appreciable enhancement in the cost of manufacture. What the measure of this enhancement may be is not susceptible of precise determination; and even an approximation to it can only be reached by persons with a minute and practical knowledge of all the details of manufacture and of trade on the one hand, and of what is required for the protection of the revenue on the other. We have, therefore, not attempted to investigate all the elements that enter into the

but have accepted the figures that have been established by law and practice as applicable to the present case. These figures will be found in Appendix No. 1, or with a full explanation of the manner in which they have been reached. For our purpose it is sufficient that they may be taken as representing an enhancement of the cost of producing plain British spirits by 2*d.* per proof gallon, or an increase of about 50 per cent. in cost that would otherwise prevail in the production of industrial alcohol. It is patent that producers thus red could not hope to compete successfully, either at home or in foreign markets, against rivals not so hampered, unless some counterpoise were afforded to the burdens that fiscal restrictions impose upon them. Accordingly, the law does provide such a counterpoise—in the case of the home market, by making the duty on imported spirits exceed the duty on British spirits by an amount equivalent to the burdens on the home market—this is called the “surtax”—and in the case of foreign markets, by granting to the home producer a rebate calculated on the same basis. These export rebates are at the rates of 3*d.* per proof gallon on plain spirits, and 5*d.* per proof gallon on compounded spirits, and is the higher of these two allowances that is taken as the measure of the “surtax” on all other spirits other than rum or brandy, on which the “surtax” is 4*d.* per proof gallon. The final result of the price of industrial spirit of all the measures taken to protect the revenue may be stated as follows. Spirit of manufacture is commonly about 64 overproof (93 per cent. on the continental standard of pure alcohol), and is plain spirit. Therefore, the price of a bulk of the spirit is about 5*d.* more than it would have been but for Excise restrictions. The cost of methylated spirit may be put at between 3*d.* and 4*d.* per bulk gallon, of the price eventually paid by the manufacturer, it present may be taken at from 20*d.* to 22*d.* per bulk for large quantities at wholesale price, about 8*d.* per bulk butable to precautions on behalf of the revenue. The two considerations (a) of the conditions in which spirit must be used, and (b) of the price at which it may be procured, affect different industries in very different degrees. Either consideration may be of vital importance to a particular industry. But, speaking generally, we have no hesitation in saying, on the evidence before us, that, taking the whole range of industrial enterprises employing alcohol, the question of price is infinitely more important of the two. The number of cases in which it has been conclusively shown that ordinary spirit is seriously detrimental by reason of its use, are remarkably few, whereas the cases are numerous in which a difference of, say, 1*d.* per bulk gallon in price of alcohol might make all the difference in profit or loss in the carrying on of an enterprise. To illustrate this, we will briefly review the evidence before us in respect of some of the more important industries employing alcohol, and in doing so will include general observations as occur to us.

COAL TAR COLOUR INDUSTRY.

We take this first because it has figured very prominently in the discussions which have led up to the inquiry. In the course of these discussions, it has frequently been asserted that the coal tar colour industry, which originated in this country, and at one time flourished in this country, has been lost to us very largely, mainly, by reason of the obstacles in the way of a cheap and untrammelled supply of alcohol. In view of the prominence given to this assertion, we thought it well, even at the risk of travelling somewhat beyond the immediate purpose of our inquiry, to procure authentic evidence upon the subject. With that object we invited Mr. W. H. Perkin, the discoverer of the first coal tar colour, Mr. R. J. Friswell, who was engaged in the manufacture of aniline dyes from 1859, and Professor Meldola, who was similarly engaged from 1870 to 1885, and to whose memorandum we directed his evidence we desire to call special attention. We also before us, as a witness nominated by the Chamber of Commerce, Professor A. G. Green,

whose name is associated with well-known coal tar colouring matters. Further, our Sub-Committee, who visited Germany had an opportunity of learning the views of many persons connected with the colour industry in that country.

15. On a review of all the evidence, pro and con, we are satisfied that, regarded as a statement of historical fact, the assertion that the coal tar colour industry has been lost to this country on account of obstacles to the supply of alcohol is destitute of substantial foundation.

16. In the earlier days of the industry alcohol was used almost wholly as a solvent, and for that purpose methylated spirit is suitable. Moreover, when alcohol first began to be used as a constituent of dyes, and until some time after the decadence of the industry in this country had become marked, the margin of profit on the manufacture was so great that the difference in price even between duty-free and duty-paid alcohol was a matter that could practically be left out of consideration.

17. It would take us too far afield to examine at length into the causes that did, in fact, contribute to the decadence of the industry in this country and to its rapid development in Germany. But much information on the subject will be found in the evidence, and here we will confine ourselves to saying that, in our opinion, the cause which predominated over all others was the failure of those responsible for the management and for the finance of the industry here, during the years 1860–1880, to realise the vital importance of its scientific side, and their consequent omission to provide adequately for its development on that side.

18. But while we say this in the interest of historical accuracy, it by no means follows that either we, or the authorities we have quoted, think that what was true of the period 1860–1880, is true of the present time. On the contrary, it is unquestionable that, in some branches of the colour industry, with alcohol playing a considerable part as a constituent of certain dyes, and with profits cut down by competition to a narrow margin, the circumstances under which, in respect of condition and of price, alcohol can be used, have become of importance. But here too, it is necessary to guard against exaggeration. Large classes of the coal tar colours—alizarin, indigo, and by far the greater number of the azo dyes—require no alcohol for their manufacture either directly or indirectly, and these represent by far the larger proportion of all the colours produced. We have had varying estimates given to us of the proportion of the whole output that demands alcohol, and they range from the 10 per cent. of the German authorities to the 20 per cent. to 25 per cent. of Professor Green. Therefore, for at least 75 per cent. of the whole industry, alcohol does not enter into account even now, and these branches could be prosecuted in this country, as indeed they now are, whatever the conditions in regard to the use of alcohol might be.

19. Nevertheless, even where alcohol is not immediately required for the manufacture of a dyestuff, the utilisation of waste products and the development of new methods may be hampered by a want of alcohol: while, for those dyestuffs for which alcohol is essential, its price and the conditions of its use are matters of great moment. We are of opinion, therefore, that, if the hope is to be entertained of recovering any considerable portion of this trade, more favourable conditions must be established in respect of the use of alcohol.

20. We may observe that in the manufacture of dyestuffs, or of the intermediate products for their manufacture the part played by methylic alcohol is far more important than is that of ethylic alcohol. Methylic alcohol is not produced by fermentation and it was not until the process of its manufacture was so far perfected as to bring it into possible competition with ethyl alcohol that it was thought necessary to subject it to the charge of the spirit duties. This was done by an Act of 1865; and in 1898 its use was prohibited in the preparation of beverages or of medicines for internal use. (28 & 29 Vict. c. 96, ss. 27, 28.) Its chemical character differs so much from that of ethyl alcohol that its presence in any product can readily be detected by analysis. In view of these facts, we think that exceptional treatment may be accorded to methylic alcohol, in the manner described later.

SMOKELESS POWDERS.

21. On the question whether in this industry ordinary methylated spirit is unsuitable or detrimental in character the evidence laid before the Committee appears to us conflicting and inconclusive. We are inclined to think that the true position is that the question has never been thoroughly sifted. As Sir W. Crookes put it to us, it is known that very slight chemical variations in the materials employed may produce very marked variations in the quality of the powder produced, more especially as regards its stability; to determine whether the chemical composition of ordinary methylated spirit (or of methylated ether) would or would not affect the stability or other properties of a powder, would demand costly experiments extending over many years; and there has not been any sufficient inducement to undertake such experiments. The Act of 1902 still further diminishes the inducement, and all the more so because there is probably no single industry in which exceptional advantages as regards the use of spirit could be accorded with less risk to the revenue. The workmen employed are of necessity men of steady and trustworthy character; they are subject to the strictest supervision; and the manner in which spirit enters into the process of manufacture gives but little opening for speculation.

22. But the question of the price of spirit and ether is one of vital importance to the manufacturer of smokeless powder of which nitro-cellulose is a constituent.* The quantity of alcohol used, either directly in the form of spirit, or indirectly in the form of ether, for the production of one pound of this powder is very large. What the exact amount may be it is difficult to determine, because so much depends upon the amount of spirit that may be recovered from any operation, and this varies as between one operation and another, and as between one factory and another. But one witness gave us to understand that a difference of 6d. per gall. in the price of spirit would make a difference of 7d. per lb. in the cost of the powder produced; and it is manifest that even a much smaller difference than that would turn the scale between profit and loss.

PHARMACEUTICAL PRODUCTS—FINE CHEMICALS.

23. In this branch of industry alcohol plays a very important part. In Section 4 of our Sub-Committee's report, the subject is very fully treated, and we will not here repeat what is there stated. We will merely observe that for a large, and probably increasing, number of substances, such as the synthetic perfumes, antipyrine, phenacetin, sulphonal, and so on, alcohol at a price not in excess of that at which it stands in competing countries, and usable under conditions not inimical to the quality and character of the compounds produced, is essential to the existence of the industry. The industry presents certain features of difficulty because, in the first place, there are large numbers of pharmaceutical preparations in which the alcohol remains as free spirit, and which must continue to be made from duty-paid spirit; and because, in the second place, the preparations are so numerous and so various in character that there are difficulties in making a single process of denaturing applicable to them all. But these difficulties have been satisfactorily overcome in Germany, and we see no reason why they should not be overcome here. We are, however, of opinion that the manufacture of synthetical chemical products with duty-free alcohol would have to be completely and effectually separated from the manufacture of preparations (as, for example, tinctures) in which the alcohol remains as such, and which, therefore, must be made with duty-paid spirit.

ETHER.

24. The production of ether has become a most important industry, large quantities being required for manufacturing purposes (e.g., smokeless powder, artificial silk, &c.) and for refrigerating purposes. For most,

if not for all of these purposes, ether made from C methylated spirit is quite suitable. But, inasmuch as it requires much more than a gallon of strong spirit to produce a gallon of ether, the price of spirit is made a consideration of primary moment to this industry. Incidentally we may mention that, in the course of evidence, the question was raised whether the rates of import duty on ethers are the correct equivalent of the duty payable on the spirit necessary to them.

ARTIFICIAL SILK.

25. This industry is not at present prosecuted in this country, although it employs many thousands of people on the Continent. Some five or six years ago an attempt was made to introduce it, and a factory established at Wolston, near Coventry, but after being open for nearly two years (1899—1900), it was closed. At that time the Excise authorities had no power to allow the use of spirit in any other form than that of ordinary methylated spirit, and in the opinion of Mr. C. was chairman of the company from its formation until some six months before it was wound up, he attended as a witness before us, the obligation of using methylated spirit was one of the causes of the failure of the enterprise. The evidence on this point is conclusive. But it is unquestionable that the opportunity of manufacture in this industry are extremely great, and that the difficulties to be overcome are in some respects great and numerous. To add to the difficulties, it is inevitable one that can be avoided would manifestly be most undesirable; and, therefore, if using methylated spirit creates a fresh difficulty, it should by all means be avoided. For the manufacture of artificial silk, the use of alcohol is a consideration of vital importance combined ether and spirit required to produce one of the finished article represents nearly a gallon of spirit.

LACQUERS, VARNISHES, Etc.

26. These are usually made with the ordinary methylated spirit, where spirit enters into the manufacture (Spirit is not required for lacquers that are applied to wood). In a few rare cases pure duty-paid spirit is employed for the finest kinds of lacquer. On the question whether methylated spirit is detrimental to the character of the product, the evidence submitted to us was conflicting, some witnesses insisting that it is detrimental, and others representing a considerable section of the trade maintaining that it is not. Specimens of goods treated with lacquer made with pure spirit, with ordinary methylated spirit, and with wood naphtha respectively, were shown to us; and we are bound to say that any difference between them was scarcely perceptible to the untrained eye.

27. However this may be, we consider that the trade neither the character nor the price of spirit under existing conditions, creates any serious hindrance, perhaps, for goods exported. For in the home market the trade enjoys a considerable measure of protection, owing to the fact that imported lacquers and varnishes containing spirit are charged full spirit duty on the quantity of spirit contained.

MOTOR VEHICLES.

28. Spirit is not used at present in this country as fuel for motor vehicles. Nor is it so used to any extent either in Germany or in France, in spite of the fact that both these countries are most desirous of encouraging the use of a material that is indigenous, in preference to a material like petrol that has to be imported. In Germany spirit is used for motor or other engines in those cases where it is almost entirely for agricultural engines. For motor cars, spirit presents certain special difficulties, which require to be overcome, the principal being the belching of alcohol in very cold weather, and the tendency of the acids generated by its combustion to cause corrosion of the metal surfaces with which they come in contact.

29. For the moment, therefore, the question of the use of spirit for motor cars is not ripe for consideration from the point of view of our inquiry. Should it be

* It is an open question amongst the authorities whether the powder of the future will be one requiring alcohol for its preparation.

so, it is manifest that alcohol used for this purpose is denatured in the most effectual and most perfect manner. Happily this will not present any difficulty, as there is no evidence to suggest that the use of methylated spirit in common use in this country is in any way unsuitable or detrimental for this purpose. Any question, therefore, of the use of spirit for other purposes will be one of price, and as at present the price of petrol is about half the price of methylated spirit, it is clear that close investigation of the matter may be required until such time as there may be an approximation in the prices of petrol and spirit sufficient to make a practical alternative of choice between the two.

GENERAL CONCLUSIONS.

In all the facts before us we have arrived at the following general conclusions:—

i.) That where spirit is used for general and various purposes, such as heating or lighting, the use of "mineralised" methylated spirit is perfectly satisfactory, both to the revenue and to the public, in respect of character, and that at present no better method of denaturing is available. In respect of price, the cost of mineralised methylated spirit is enhanced by some 40 per cent. by reason of measures necessary for the protection of the revenue. But to intervene such enhancement would be merely to place the whole community at a burden in one direction by putting upon it an equivalent burden in another, seeing that the cost of relief would necessarily have to be made up to the Exchequer from some other source of taxation. Thus there would be no real increase of gain to the community as a whole from arrangements that would of necessity be somewhat complex, and would entail a certain cost in their execution. We think, however, that, having regard to the practical security that is provided for the revenue by the process of denaturing adopted in the case of this spirit, the regulations in regard to distribution might be appreciably relaxed in respect of the quantities that retailers may keep in stock, or may sell at any one time to a customer. We recommend that the regulations should be left to be prescribed from time to time by the Board of Inland Revenue, instead of being stereotyped in the Statutes.

ii.) That where spirit is used for industrial purposes, the Finance Act of 1902 provides adequate and entirely satisfactory machinery for securing that the spirit may be used in a condition that is suitable and appropriate to each particular purpose of manufacture. The machinery is elastic—much more so than is the corresponding machinery in Germany—it permits of every reasonable process of denaturing, or even, in the last resort, of the use of spirit in a pure state. For more than this it would be impossible to ask.

iii.) That something more is required in order to secure spirit used as an instrument or a material of manufacture on a footing satisfactory in the matter of cost. Anything in the nature of a bounty is desirable. But seeing that on the price of spirit the very existence of certain industries may depend, and that for all industries using alcohol the price of spirit is an important factor for that portion of trade that is outside the home market, we are strongly of opinion that it is desirable to make such arrangements will free the price of industrial spirit from the enhancement due to the indirect influence of the spirit duties. It would surely be disastrous if, to the chief that the drinking of alcohol causes by diminution in the efficiency of labour, the taxation of alcohol should be allowed to add the further mischief of narrowing the openings for the employment of our

men. In our opinion, there is only one way in which the cost of the spirit duties can be satisfactorily counteracted in favour of industrial alcohol. To diminish the restrictions on the manufacture of alcohol might do the influence, but probably not to any great extent.

For with a duty of over 1000 per cent. on the

prime cost of an article, revenue control must of necessity be strict. Moreover, the gain to industry would be made at the risk of the revenue, and a duty that yields over 20,000,000*l.* per annum to the Exchequer is a public interest that cannot be trifled with. To relieve imported spirit from the surtax which is needed to counterbalance the burden imposed on production in this country by the Excise regulations would be manifestly unfair; and its effect would be to give to the State-aided spirits from Germany or Russia a practical monopoly of the market in this country for industrial spirit. The only adequate course, it seems to us, is to neutralise, for industrial spirit, the enhanced cost of production due to Excise control, in the same way as the enhanced cost is neutralised for exports, *viz.*, by granting an allowance on such spirit at such rate as may from time to time be taken as the equivalent of the increase in cost of production due to revenue restrictions. At the present time, the rate is taken at 3*d.* per proof gallon for plain spirits, and the allowance would accordingly be at this rate, and should be paid equally on all industrial spirit whether it be of British or of foreign origin.

33. We do not suggest that the cost of methylation should be borne by the State, although a strictly logical application of the principle of attempting to put industrial alcohol on the footing that it would occupy, if there were no duties on spirit, might seem to require this further concession. For we hold that the manufacturer using alcohol has so strong an interest in rendering it unpotable for his own protection that he may fairly be asked to accept denaturing as a necessary incident of use, the cost of which he should bear.

34. At the same time we think that the charge on the manufacturer might reasonably be limited to paying the cost of the denaturing agents and of the mixing of them with the spirit; and that he should not be required to pay the cost of regular attendance of the Excise officers, which is given wholly in the interests of the revenue. Attendances at irregular times, at the special request and for the special convenience of the manufacturer, might, if necessary, continue to be charged against him.

35. We think that for ordinary methylated spirit (which will continue to be used for many industrial purposes for which it is not, in the words of the Act of 1902, "unsuitable or detrimental") the formula of methylation may safely be modified, and the proportion of wood naphtha reduced, so that the mixture may consist of ninety-five volumes of spirit to five of wood naphtha. This will at once somewhat cheapen the methylated spirit, and will also diminish any prejudicial effect that the chemical properties of wood naphtha may have for certain manufactures; while it will continue to "mark" the spirit sufficiently to allow of detection by analysis, should the methylated spirit be used for any improper purpose. It must be remembered that this kind of methylated spirit can only be used by persons holding an authority from, and under heavy bond to, the Commissioners of Inland Revenue (whereby its employment is subject to control and supervision, which can be graduated according to circumstances), and that consequently the risk of fraud is limited.

36. We have mentioned that we think that methylic alcohol used for industrial purposes, might be accorded special treatment. We understand that the Board of Inland Revenue do not consider that it would be wise to revert to the position obtaining before 1866, when methylic alcohol was regarded as wholly outside the scope of the spirit duties; and their opinion receives support from the fact that in France the law has recently been altered so as to define more precisely the degree of purity which shall render methylic alcohol liable to duty. The object we have in view can, however, be sufficiently met without taking methylic alcohol out of the charge for duty. It would meet all requirements in respect of methylic alcohol, if it were exempted from the condition of the proviso to Section 8 of the Act of 1902, which requires payment of the surtax on all imported spirit used for manufacture, and if the Board of Inland Revenue should exercise their discretion under the section in the matter of denaturing in such a way as to permit the use of methylic alcohol practically pure. Thus, we under-

stand, they would be willing to do; and exaction from the surtax would be fully justified, inasmuch as the manufacture of methyl alcohol in the United Kingdom is not, in fact, subjected to any restrictions that enhance the cost of its production.

37. While making the concessions above described, we think it would be right, in the interests of the revenue, that special denaturing agents authorised for use in particular industries, should be subject to official test; and further that manufacturers who are authorised to employ specially denatured alcohol should be required to keep such books as may be prescribed, showing the receipts and uses of spirit, the manner in which it has been distributed to the several branches or departments of the factory, and the quantities produced of the articles manufactured with it.

38. We believe that the recommendations we have made, if adopted, will place the manufacturers of this country in respect of the use of alcohol in industry on a footing of equality, in some respects of advantage, as compared with their competitors abroad. Amongst the witnesses who appeared before us, we found a very general impression that, in Germany at any rate, and Germany is our most formidable competitor in this field, spirit could be used in manufacture duty-free and pure, with scarcely any restraint. This is very far from being the case, as the report of our Sub-Committee shows. As regards price, the grant of the export allowance would, we believe, make the average price of industrial spirit in the United Kingdom even lower than the average price in Germany. The price, exclusive of the cost of any denaturing, would, under present conditions, be about 7d. per proof gall., or about 11½d. the bulk gall. at 64 over proof—the strength common in industrial spirit. That is as low as the minimum price paid by users in Germany in the year 1902, when spirit was abnormally low, and is much below the figures of 1s. 3½d. per proof gall., and of 2s. 1½d. per bulk gall. prevailing in Germany at the present time. Further, the price of spirit in this country, where all materials may be freely used, and where none of general use are subject to taxation, is a stable price. In Germany the conditions of production tend to wide and rapid fluctuations in price.

39. At the same time, it would be a mistake to suppose that any facilities given for the use of spirit in this country are likely to create such an increased demand for spirit as to produce any shortage of supply, and so to lead to a rise in price. This point is fully discussed in Section 9 of our Sub-Committee's Report, and we see no reason to dissent from the conclusion that any increase in the demand for industrial spirit must for a long time to come be well within the limit of 3½ millions of proof galls. This estimate serves also to assign a limit within which the charge to the Exchequer, resulting from the proposed allowance of 2d. per proof gall. on industrial spirit, will be confined. The present consumption of such spirit is about 3½ million proof galls., on which the allowance would aggregate 40,000*l.* The utmost expansion that can be regarded as attainable within a measurable distance of time would double that sum, and it may safely be assumed that any immediate expansion will be moderate and gradual.

40. For convenience of reference we summarise our several recommendations:

(i.) That an allowance be granted to all industrial spirit, whether of British or foreign origin, at the rate from time to time prevailing for the allowance to British plain spirits on export.

(ii.) That imported methyl alcohol be relieved from the obligation to pay the surtax imposed by the proviso to Section 8 of the Finance Act, 1902; and that methyl alcohol be accorded favourable treatment in the matter of denaturing.

(iii.) That "ordinary" methylated spirit should contain only 5 per cent. of wood naphtha, instead of 10 per cent.

(iv.) That no charge should be made on manufacturers for the regular attendance of Excise officers to supervise denaturing operations or the use of denatured spirit, in factories taking the benefit of Section 8 of the Finance Act, 1902.

(v.) That where spirit is allowed to be de-natured with special agents such agents should be subject to official test and approval; and that accounts be kept by the user showing receipts of spirit, the issues thereof from store in detail, and the quantities of goods produced.

(vi.) That in the manufacture of fine chemicals and pharmaceutical products, spirit specially denatured should be allowed only where the manufacture is kept entirely separate from the manufacture of tinctures and other preparations in which spirit remains as spirit in the finished product.

(vii.) That the regulations governing the retail of mineralised methylated spirit should be made less stringent and more elastic.

Any special cases, such as that of smokeless powder, not touched by the above recommendations, can be met under the powers conferred by Section 8 of the Act of 1902.

41. In concluding our report, we desire to express our indebtedness to our Secretary, Mr. E. C. Cunningham, whose service in that capacity has been of great value to the Committee.

We have the honour to be, Sir,
Your obedient servants,

H. W. PRIMROSE,
WILLIAM CROOKES,
W. H. HOLLAND,
JOHN SCOTT MONTAGU,
WM. SOMERVILLE,
T. E. THORPE,
THOMAS TYLER,
E. C. CUNNINGHAM (Secretary).

March 23, 1905.

ABSTRACT OF THE REPORT OF SUB-COMMITTEE ON VISIT TO GERMANY.

The Sub-Committee consisted of Sir H. W. Primrose, K.C.B., Chairman of the Board of Inland Revenue; Dr. T. E. Thorpe, C.B., F.R.S., Head of the Government Laboratory.

We have the honour to report that we left London on the morning of January 14th, returning on the 26th.

We spent six days in Berlin, and while there, we were given the most cordial and unremitting attention from the Comptroller-General, Herr von Buchka, through our Ambassador, we had been referred to the Excellency the Secretary to the Imperial Treasury, and we desire to record our sense of the very great obligations which we feel to those gentlemen.

From Berlin we went on to Heidelberg and Darmstadt, returning through Cologne.

We give the result of our inquiries in full detail in the sections relating to the several heads. The outcome of them may be briefly summarised as follows:—

(1.) That the German system, in regard to the spirit for industrial purposes, is correctly stated in Appendix No. III., as laid before the Committee.

(2.) That this system, while designed on liberal and comprehensive lines, is rigidly enforced, and allows of few exceptions in practice to the rules as laid down. The only exception is that of smokeless powder, which can be manufactured in Germany with duty-free spirit, unless it be subjected before use to some process of denaturing.

(3.) That the rules can only be varied by authority of the Bundesrath, or Federal Council of the Empire, and that procedure that demands considerable time.

(4.) That the price of spirit in Germany for industrial purposes fluctuates very widely; that at the present time it is considerably higher than the price of similar spirit of British manufacture in this country; and that in normal years its price is not as much below the price in this country as the Committee have been led to suppose.

(5.) That the consumption of spirit in Germany for domestic and industrial purposes affords no standard

to measure the possible consumption for similar cases in the United Kingdom.

SECTION I.

Official Regulations.

whole of our first day in Berlin we spent in going through the published official regulations as to spirit duty-free for industrial and other purposes. Dr. von Buchka, the head of the chemical branch of the department.

As a result we are enabled to state that the abstract of regulations as given in Appendix No. III. is perfectly correct, and that practice conforms exactly to the regulations.

Accordingly the rules and practice of the German Empire may be briefly described as follows:—

Spirit may be used duty-free in a pure, undenatured form only in a very limited number of cases, *viz.*:—

- (a.) In public, *i.e.*, State, or municipal, hospitals;
- (b.) In similar scientific institutions;
- (c.) For making smokeless powder, fuses and fulminates.

For all other purposes, without exception, duty-free spirit must be used, *unless* the spirit be subjected to the authorised process of denaturing prior to use.

The authorised processes of denaturing fall into two classes, according as they result in:—

- A. Complete Denaturing.
- B. Incomplete Denaturing.

The processes authorised for "Complete Denaturing" are two, *viz.*:—

- (a.) An admixture with every 100 litres of spirit $2\frac{1}{2}$ litres of a mixture containing 4 parts of wood naphtha and 1 part of pyridine bases. (To this mixture 50 grms. of lavender or rosemary oil may be added optionally, to counteract the smell of the ridine bases. But the addition is seldom made.) Spirit thus denatured is what is used for domestic purposes—heating, lighting, and cooking. It is seldom used for industrial purposes. The only purpose of that kind for which its employment is considerable is the manufacture of cheap varnish.
- (b.) An admixture with the spirit of half the quantity (*viz.*, $1\frac{1}{2}$ litres per 100 litres of spirit) of the above denaturing mixture, together with an addition of $\frac{1}{2}$ litre of a solution of methyl violet dye and of benzol in quantities that may range from 2 to 20 litres every 100 litres of spirit.

Though spirit thus treated is classed as completely denatured, its use is limited to agricultural and motor uses, and the process would seem to fall more properly under B.

Spirit thus denatured is used in practice almost entirely for agricultural engines, as no satisfactory solution has yet been found of certain difficulties which beset the use of spirit for motor cars.

The processes authorised for "Incomplete Denaturing" are numerous. They consist—

- (a.) Of two alternative processes of general application, *viz.*:—The addition to every 100 litres of spirit of either 5 litres of wood naphtha, or $\frac{1}{2}$ litre of pyridine bases.
- (b.) Of numerous processes of special application.

These are fully set out in an Appendix. But the processes applicable to the most numerous and most important industries, including coal tar colours and chemical preparations, are the four alternatives of—

An addition to every 100 litres of spirit of 10 litres of sulphuric ether, or 1 litre of benzol, or $\frac{1}{2}$ litre of turpentine, or 0.025 litre of animal oil.

We may observe that the above regulations are applicable only to ethyl alcohol. Methyl alcohol does not fall within the charge to spirit duty in Germany, and is used freely for industrial purposes, without control by revenue authorities.

(7.) The schedule of authorised denaturing agents cannot be varied by the Executive. Any amendment of it, in addition to it, must be sanctioned by the Bundesrath, or Federal Council of the Empire; and the procedure for obtaining such sanction occupies many months, probably never less than six.

We add from our notes a few general observations and others bearing upon points referred to by witnesses who have given evidence before the Committee.

(i.) The rules are strictly enforced and no exceptions to them are allowed.

(ii.) The revenue authorities regard them as being as little stringent as is compatible with the safety of the spirit revenue, even with the present low duty on spirit. They considered that, if the duties were ever to be raised, it would be necessary to revise the regulations, and to make them less lenient in certain directions.

(iii.) The revenue authorities regard as a valuable safeguard to the revenue the obligation on manufacturers to keep "stock accounts" and "control books." They do not consider that it causes to manufacturers any serious difficulty or inconvenience.

(iv.) For lacquer-making a considerable quantity of wood naphtha denatured spirit is used in Nuremberg, Baden and Bavaria. Elsewhere turpentine is almost universally employed as the denaturing agent. No lacquers, polishes or varnishes can be made in Germany with pure duty-free spirit, or with admixture only of shellac.

(v.) *Photographic Collodion*.—It is the common opinion in Germany that the British-made collodion is better than the German.

(vi.) *Edible Oils*.—No special process of denaturing is prescribed for these. Therefore the general incomplete denaturing agents must be used, *i.e.*, wood naphtha, or pyridine bases—see above 5 (a.)

(vii.) All alcohol-containing medicines must now be made with duty-paid spirit, even veterinary medicines. The privilege of using pure undenatured duty-free alcohol for such purpose was taken away in October, 1903.

(viii.) Tinctures are not allowed drawback on exportation, unless manufactured under Excise supervision (in bond).

No drawback, or allowance in the nature of drawback, is given under any circumstances in respect of articles manufactured with denatured spirit.

SECTION 2.

It was our desire to see the working of the system in factories typical of as many of the principal industries using alcohol as it might be possible for us to visit without unduly extending the period or the circuit of our tour. We failed, however, to accomplish this object in respect of factories for the production of synthetic perfumes, of varnish, and of coal tar colours. For the following reasons:

Synthetic Perfumes.

Dr. von Buchka very kindly addressed, on our behalf, the firm of Messrs. Schimmel, of Leipzig, the principal manufacturers in Germany of synthetic perfumes. But those gentlemen informed him that it was against the rule of their establishment to admit visitors, and that they regretted that to this rule they could make no exception.

Varnish.

This industry is not carried on to any great extent in Berlin. But Dr. Wittelschöfer, managing director of the Centrale für Spiritus Verwerthung, kindly made efforts, on our behalf, to obtain admission to the one important establishment of the kind in the city. Owing, however, to the absence of the principal partners, there was no one who possessed the requisite authority to give permission for our visit during the days we were in Berlin, and we did not think it worth while to prolong our stay for the purpose of obtaining an opportunity, as the facts and position in regard to lacquer and varnish are so clear as not to demand any further special elucidation.

Coal Tar Colours.

Before leaving England, Dr. Thorpe had addressed to Dr. Glaser—a personal friend of his, and a former director (now a member of the Advisory Committee) of the *Badische Anilin und Soda Fabrik* of Ludwigshafen—a request that we might be permitted to visit that establishment. The directors felt some difficulty in acceding to this request. They, however, deputed Dr. Ehrhardt, one of their chemists, to wait upon us at Heidelberg with Dr. Glaser, in order to explain their position, and to give us such information as he properly could in regard to the special subject of our inquiry. We, accordingly, had the advantage of a conversation of some two hours' duration with him and Dr. Glaser together, and from our notes of it we abstract the following items.

Dr. Ehrhardt felt great difficulty in offering an opinion as to the proportion of coal tar dyes, whether by way of value or of quantity, which require the use of alcohol in their manufacture, but was inclined to accept as probably correct an estimate which had been given to us in Berlin by a very competent authority, and which placed the proportion at 10 per cent. of the whole. He observed that indigo and alizarine, neither of which requires the use of alcohol, would account for at least one-half of the production of the *Badische Fabrik*. In addition there was the large class of azo colours which made up a large proportion of the rest of the colouring matters made by the company, and of which only a very few individuals require alcohol.

Asked whether, in these circumstances, it might not be possible to engage profitably in the manufacture of the 90 per cent. of dye stuffs that need no alcohol, while neglecting those that required alcohol, Dr. Ehrhardt remarked that such an enterprise would be at a disadvantage as regards the by-products, for the profitable utilisation of which research, demanding alcohol, was necessary.

On the question of the proportion that the cost of alcohol bore to the total cost of production of coal tar colours, Dr. Ehrhardt felt unable to offer an opinion; but he regarded as quite possible an estimate of $\frac{1}{2}$ per cent. which had been given to us in Berlin by the authority previously mentioned.

Duty-free alcohol in a pure state is not allowed under any circumstances, not even in the laboratory.

The denaturants employed by the *Badische Fabrik* are animal oil, pyridine, and sometimes the colour to be manufactured.

The importation into Germany of English-made colours or intermediate products is small and is confined to a few specialties.

The total number of persons employed in the *Fabrik* is between 7,000 and 8,000, of whom a large number are boys; no women. Of these only a very few could ever have access to the spirit used, at a stage at which it might conceivably be drunk, and these few would always be under supervision.

There is no particular tendency at the *Fabrik* to avoid the use of alcohol, the restrictions not being found, onerously burdensome.

On the general question of the causes which have led to the great development of the coal-tar industry in Germany and its decline, or at any rate, its stagnation in Great Britain, we had much interesting talk with Dr. Glaser and Dr. Ehrhardt, and also on the following day at Mannheim with Dr. Caro, who may be regarded as one of the principal founders of the industry in Germany. They all agreed that, as an historical fact, the question of alcohol had little or nothing to do with the matter. Dr. Caro pointed out that the movement had begun, and had reached a point of considerable advancement, before the time at which the use of alcohol otherwise than as a solvent—a purpose for which methylated spirit is perfectly suited—had been appreciably developed, and before the time at which reduction in the selling price of dyestuffs through competition had rendered economy in production of serious importance.

In Germany the rise of the industry coincided with an immense development of activity in the study of organic chemistry and in its application to industry, stimulated

largely by the influence of Kekulé, his coadjutors and immediate followers. Dr. Glaser gave it as his opinion that Kekulé's conception of the chemical structure of benzol was the germ out of which has grown the colour industry. The output of chemists by the Universities was relatively enormous, and has continued to be so for the past forty years, and the services of competent chemists became obtainable at salaries of more than £100 per annum. Consequently, they were engaged by hundreds to act practically as foremen in the works, and the whole of the subordinate supervision was in the hands of scientifically trained men. This was of it advantage to the business of manufacture, and at the same time it provided a large field from which to select more competent men for the work of research and invention; and those thus advanced were engaged in a leading part in the management and in the profitable business.

Nothing of the kind was possible in England at that time.

At the same time, these gentlemen all recognised that as things are at the present day, when alcohol so largely enters into the composition of colouring matters, when the profits on the manufacture of coal tar dye intermediate products have been cut down by competition to a narrow margin, the question of alcohol, of the extent at which it can be procured, and of the facilities for its employment—has become a matter of great and of cardinal importance.

[SECTION 3 is devoted to a description of the operations of complete denaturing.]

SECTION 4.

Pharmaceutical Products—Fine Chemicals.

As is well known, Germany has long enjoyed pre-eminence in the manufacture of the products which are generically as "fine" chemicals, in contradistinction to "heavy" chemicals such as the mineral acids, bleaching powder, alum, &c., mainly inorganic substances which hitherto have been the chief staple chemical products of this country. Germany too has made almost exclusively the now numerous pharmaceutical products, which are definite organic compounds, often of complex chemical constitution, largely obtained by synthetic processes and which may be said to depend upon the industrial application of the laboratory processes and methods of modern organic research.

As it is frequently alleged in this country that the eminence is largely, if not entirely, due to the facility of comparative cheapness with which ordinary alcohol, pure and suitably denatured, is obtained by chemical manufactures in Germany, it was of great importance in our inquiry to obtain trustworthy first-hand information on the subject.

We accordingly solicited permission to visit the establishments of E. Merck, in Darmstadt, and of the *Chemische Fabrik Auf Aetion* (vorm. E. Schering) at Berlin—among these as among the most representative and most comprehensive manufacturing establishments of these particular classes of products, and to have the opportunity of conferring with those responsible for their direction and management. Both factories have a world-wide reputation and have branch houses or agencies in almost every country in both hemispheres.

Permission was readily granted in each case, and every facility was afforded to us to acquire information on the special subject of our inquiry, and to see operations involving the use of alcohol, its custody and control, methods of denaturing, processes of recovery, revenue checks, &c. We cannot too gratefully acknowledge the courtesy with which we were received, the readiness with which information as we could reasonably ask for was given, and the freedom with which illustrative or typical processes of some of them unique, were exhibited and explained.

Whilst at Berlin, we were invited by Dr. Bötting of the well-known Bayer Company, to visit the newly erected factory at Leverkusen, but as we were at the time

informed that they do not use or denature any spirit at work, we were reluctantly obliged on account of short time at our disposal, to decline the opportunity of seeing what Professor Witt described as the best denatured works of the kind in Germany.

We visited the Charlottenburg branch of the Chemische Fabrik Actien (vorm. E. Schering), which we visited first, and then received by Dr. O. Antriek. By arrangement with the company, we so timed our visit as to be able to see a denaturing operation on the large scale, having been informed by Dr. Antriek that such an operation had been arranged for prior to our application.

The denaturant mainly in use in this factory is annual which is mixed under the direction of the revenue officers, in the proportion required by the regulation. A sample of the bone-oil used must be of the character fully prescribed. It is received at the works under a seal, accompanied by a certificate of its validity from a sworn chemist, recognised by the revenue officers. The only other denaturant employed in the works is ether which is admitted under the direction of the revenue officers to the extent of 10 per cent. The employee must be certified to be of the official character before admission.

The expenses of methylation, not only the cost of the denaturants themselves, but the fee for the chemist's analyses and certificates, as well as the charges for the attendance of the officer, the cost of handling, mixing, &c., are borne by the manufacturers, who are required to furnish the gauge glasses, standardised hydrometers, weighing machines, mixing machines, mixing rods, furniture, in fact everything needed to carry out the process, as prescribed, without charge to the State.

100 hectolitres of alcohol are employed in the course of a year. The proportion of ether alcohol to bone-oil alcohol used is roughly as 2 to 7. No duty-free pure alcohol is allowed.

The amount of clerical work needed, and the system of supervision and control in force, struck us as greater and more detailed than English users of alcohol under the regulations have hitherto been subjected to. Dr. Antriek considered, however, that in a works of the magnitude and character of Schering's, the system was not too strict, and they had little difficulty in complying with the official requirements, although he admitted that in smaller works there were occasional complaints of the strictness of the system. We had further an opportunity of seeing operations in which the denatured spirit was recovered and partially recovered, and we saw the method of recovery and rectification of the alcohol in actual use. We were also shown how the recovered alcohol was stored, brought to account, and how the necessary re-denaturing was effected.

A new factory of E. Merck, of Darmstadt, is now being erected on premises in the Frankfurter Strasse, some miles outside the town.

The denaturants allowed by the regulations, including special ones used in the manufacture of iodoform, chloroform and ethyl bromide, are employed. The official denatured alcohol, containing wood naphthalene and pyridine bases is used, but not for many purposes, and in small quantities. In all about 100,000 kilos. of alcohol are denatured annually, in addition to which large quantities of duty-paid spirit are used, over which there is official control. The use of pure alcohol without duty is allowed. No precise estimate could be given, at the time of the number of the 3000 products which need duty, but two of the partners, including the head of the factory management, agreed that it could not exceed 10 per cent. The value of the alcohol used, as compared with the value of the finished products could not at once be ascertained; it, of course, varies largely with the nature of the products, but was probably not more than from 10 to 20 per cent. Special methods are employed for recovering the last traces of the denaturants from the finished products, some of which were described to us, according to the number of denaturants allowed no particular difficulty seems to occur in this respect, although in some cases duty-paid alcohol must be employed. It was stated that the principle of *ad hoc* denaturation is regarded with favour by the German revenue

officials, and in many cases the privilege of exportation has been withdrawn.

We inspected the spirit stores and inquired into the methods of custody, control and distribution of the duty-free alcohol, and we had also an opportunity of witnessing a denaturing operation. The method, in principle, was precisely similar to that we had seen at Charlottenburg, although the arrangements for the convenience of the revenue officials were slightly different. These officials are required to attend for denaturing about twice a week. The cost of attendance is about 6 marks per officer per day—say, 24 marks a week. Sometimes, however, a third officer is required. The cost of this attendance is considered of less consequence than the trouble it involves. We were informed that the present price of Prussian spirit is 67 marks per 100 kilos. (=2s. 2d. per bulk gall.), which does not include the vat tax, but includes the distillery tax, which amounts to 7-16 marks per 100 kilos. For purposes of rebate, a running account is kept, and the payments are made about every three months. No export business involving drawbacks on exportation is done at Darmstadt.

We inspected some of the control books relating to alcohol in the separate factories. The superintending chemist in charge of each department is personally responsible for the accuracy of the control book, and for the proper use of the spirit served out to him.

As regards ether, we were informed that this article may not be retailed, except when made from duty-paid spirit. A pharmacist may only receive it under permit, and may not sell it for medicinal purposes, unless prescribed by a physician. This procedure is adopted with a view of stopping the practice of drinking ether as an intoxicant.

In hospitals, ether may, by special permission, be used duty-free for anaesthetical purposes, and its use is also permitted, duty-free, in the laboratories of those educational institutions which are allowed to use duty-free alcohol.

SECTION 5.

Agricultural Distilleries; Marienfelde.

Finding that there was in the neighbourhood of Berlin an example of an agricultural distillery, we took advantage of the opportunity and paid a visit to it.

It was situated at Marienfelde, some ten miles to the south of Berlin, on a large and apparently very flourishing farm. The distillery was at work, and we were enabled therefore to study the system in operation.

The procedure is as follows:—

The potatoes (which must be produced on the land of the proprietor) are first washed by machinery. They are then steamed and pulped, and driven through a strainer into the mash-tun where they are mixed with a small percentage of malt. The wort is then passed into the fermenting vats. Each vat is gauged, and its content marked on the outside, together with the number of the vat. The wash is left to ferment for thirty hours, and is then conveyed to the still, which is of the patent-still type. On issuing from the condenser the spirit passes first through a domed glass case in which is a cup. In this cup, into which the spirit flows and from which it overflows, there float a thermometer and a hydrometer, to indicate the strength of the spirit passing. From this apparatus the spirit flows into a (Siemens) meter, fitted with an indicator which records the quantity, reduced to the standard of pure alcohol, of spirit transmitted, and from the meter the spirit passes on to the receiver.

The system of control does not require the continuous attendance of Excise officers, but is compounded of—

- (1) Mechanical contrivances,
- (2) Book entries,
- (3) Liability to visitation at any time.

(1.) Mechanical Contrivances.

Up to the point at which the wash passes into the still, these are limited to the gauging of the vats and to the plumbing under revenue seal of all joints of the pipes leading from the vats to the still. From that point onwards to the receiver every vessel is locked and sealed,

and no access to the spirit can be obtained by the distiller. As the manager expressed it to us, "Up to this point I am treated as an honest man. Afterwards I am no longer trusted."

In the smaller distilleries the meter, which no doubt is an expensive apparatus, is dispensed with, and the quantity of spirit distilled is ascertained by the Excise officer from the receiver. Whether there be a meter or not, the receiver is of course under lock, and is not accessible to the distiller.

(2.) Book Entries.

The regulations require entry of the quantity of materials used. But we understood that this was regarded as of little practical value, and that little attention was paid to such records. It is manifest that they cannot be susceptible of any real check.

The important entries are those of the times of charging and discharging the several fermenting vats, and of the quantities of wash in each. These entries can of course be checked against the spirit found in the receiver, and on them is computed the vat-tax and the distillery tax, which have to be paid by the distiller.

(3.) Liability to Visitation.

It will be seen that the control under (1) and (2) provides no security against abstraction of wash from the fermenting vats. Visitation at frequent and uncertain intervals would seem to be an essential feature of the system, and we gathered that at Marienfelde the visits of Excise officers were even unpleasantly frequent. Whether they are so in more remote distilleries may be open to doubt.

In any case we are of opinion that the system of control rests so heavily upon confidence that, while it may be satisfactory with a low duty on spirits and with a system of rebates of duty that makes the Excise a source of profit to the smaller distiller, it could not safely be adopted where the duty is as high as it is in the United Kingdom and invariable in its incidence.

The distillery at Marienfelde is one of the best and largest type of agricultural distillery. Its "contingent" is 600 hectolitres per annum, or about 23,000 proof galls. of spirit. Out of the total number of agricultural distilleries in the German Empire there are not more than some 2000 or 3000 of similar size and character.

The vast majority of the agricultural distilleries are to be found in the eastern provinces of Prussia and Saxony, where the soil is poor, and the cost of conveying agricultural produce to a remunerative market is high; and it is not quite clear to us how it can be commercially profitable on a fertile farm close to Berlin to convert potatoes into spirit. The manager informed us that in the present year, even with the abnormally high price of spirit, he would realise on his potatoes used for distillation no more than from 2*l.* to 2*l.* 5*s.* per ton, whereas if sold for consumption as potatoes, they would realise some 4*l.* per ton. He was, however, compelled to use them in the distillery, in order to maintain his "contingent," which might be reduced if he should fail in any season to reach his prescribed production of 600 hectolitres. Moreover we doubt whether the above figure of return on the potatoes included the bonus of 20 marks (1*l.*) per hectolitre on the amount of the contingent. This would be equal to more than another 1*l.* per ton for the potatoes used.

We think the explanation of the maintenance of this distillery is that it is kept up to some extent as a convenient object-lesson in the neighbourhood of Berlin, for the instruction of Excise officers, and to illustrate the teaching at the Institut für Gährungsgewerbe und Stärkefabrikation in Berlin, an institution established by the trades, with assistance from the Government for the purpose of giving instruction in brewing, distilling, and other processes in which fermentation is employed.

We were informed that in normal years the return from potatoes used in the agricultural distilleries does not exceed some 25*s.* per ton (exclusive presumably of

bonuses), and in many cases is less. The average is 20*s.* per ton.

The yield of alcohol from a ton of potatoes may be taken at about 25 galls. of pure alcohol, or about 44 galls.

SECTION 6.

Vinegar Factory.

We visited a large establishment in Berlin for the manufacture of vinegar from alcohol, one of several worked by the same proprietors (Messrs. Kühne) in different parts of the Empire.

The process is exceedingly simple. The spirit, the account has been taken in the usual way by the officers, is poured, together with the prescribed quantity of vinegar and water, through a scupper in the pavement of the receiving floor into tanks in the basement. These the mixture is pumped up to the topmost floor of a high building, whence it percolates down through a series of vats, floor by floor, filled with wood shavings and containing the food for the organisms which effect the fermentation, and arranged so as to secure the maximum exposure of the liquid to the air. The liquid returns to the basement in the form of the finished product (vinegar), the whole circuit occupying not more than three or four hours.

The quantity of vinegar produced of the strength of 7 per cent. of acetic acid is about 10 times the quantity of alcohol used.

There is a loss of some 30 per cent. of the alcohol by evaporation.

In this industry the control over the spirit employed is less exacting than in the case of any other industry in Germany. From the time when the spirit is denatured no further control is exercised over it. No books are kept to show how it has been disposed of, or the yield of vinegar has been; nor is there any restriction of the manufacturing premises by the Excise officers. The one and only regulation imposed for the protection of the revenue is a prohibition against keeping a still on the premises. It is true that the denaturation of the spirit is such that there is no apprehension of its being drunk on the premises without purification. But even so, the system of control seems dangerously confiding, and the authorities of the Treasury frankly admitted that it could not be justified in principle.

The Government, however, have been reluctant to disturb it; partly because it is of long standing, and believed to lead to abuse in practice; but principally because this process of vinegar making can even now with difficulty hold its own against the process of manufacture from pyroligneous acid, and because it is feared that the curtailment of the present privileges of the industry seriously endanger its very existence.

It is, however, felt that if at any time the duty on spirit should be raised in Germany it would be hardly possible to maintain the present system of control without modification.

In these circumstances it seems highly improbable that the process, which is at present not practised in the United Kingdom, could with advantage be introduced into this country.

The quantity of spirit used for the manufacture of vinegar in the German Empire was, for the year 1903, 6,000,000 proof galls.

The quantity used in the factory we visited is about 150,000 proof galls.

SECTION 7.

A German Methylating Factory: Fürsteneuland.

Much, if not the greater portion, of the pure denatured spirit used by the German manufacturers is denatured in the works in which it is actually employed, and this is invariably the case where the volume of spirit handled is large. Owing, however, to the fact that the freight-charges on pure alcohol are higher than on denatured spirit—a difference which the German chemists

manufacturers are struggling to remove—and to other instances, arrangements are made whereby manufacturers requiring only a relatively small quantity of pure spirit, either complete or partial, may obtain from professed methylators, working under revenue supervision.

On the suggestion of Dr. Korenber and Dr. von Buchla, who were kind enough to accompany us, we visited such an establishment at Fürstenwalde, a town on the Spree, about 30 miles south-east of Berlin, and within easy communication of the district of Posen where the use of the agricultural spirit is made.

On our arrival we were received by the proprietors of the establishment, B. Hecker and W. Zeidler, one of whom made up for us, in turn, every form of denatured alcohol which the regulations permitted the firm to prepare. The origin, character and sources of supply of each denaturant were explained to us, and samples of the various articles, duly certified to be in conformity with the prescribed regulations, were shown to us.

Wood naphtha used for denaturing contains much less methyl alcohol than is customary in this country; in fact, the quantity does not exceed 55 per cent. On the other hand, the regulations prescribe that it must contain at least 25 per cent. of acetone—a relatively inactive substance, probably not so useful as an indicator or "ear-marking" material as methyl alcohol, and, as we were given to understand, somewhat prejudicial to the health of wood naphtha and of methylated spirit in certain manufacturing operations.

"Pyridine bases" employed come largely from Germany, although other sources of supply are available, and, owing to the increasing demand for these substances as the raw material for the manufacture of a number of special products, has risen considerably of late, and although used in only relatively small quantities, for the most part in connection with the completely denatured spirit intended for heating, lighting and power, the increase in price is beginning to be felt. Considering comparatively high prices of spirit in Germany at present time, and the consequent restriction in the use of spirit for general or household purposes, which is by no means the largest outlet for industrial spirit in that country, the cheapening of the cost of denaturing becomes a matter for serious consideration.

The addition of lavender or rosemary oil, which is natural, and to the extent of 0.125 per cent., to the completely denatured spirit is seldom made, except for special purposes, as in soap-making. This addition was originally introduced to meet a possible popular prejudice against the use of denatured spirit in households, owing to the pungent character of the pyridine bases. The prejudice, if it ever existed, apparently no longer obtains, although it must be said that the German methylated spirit is far more palatable, as regards smell, than that in common use in England.

At Fürstenwalde Works mix considerable quantities of a general denaturant—that is the mixture of four parts of wood naphtha and one part of pyridine bases—and a small quantity of lavender oil is added to the spirit in the proportion of 2½ litres to every 100 litres of alcohol. The quantity of the mixed denaturant made per annum is about 800,000 litres—which is about one-third of the quantity made in Germany.

We saw the operation of preparing the mixture. The wood naphtha was received in iron drums, the tare of which was noted. It is examined and certified as to character, and the weight of the wood spirit having been ascertained, the necessary arrangements and in the manner already described, the requisite proportion of authenticated pyridine base added in carboys is calculated, and that amount weighed out. The wood naphtha is then poured into a tank, and forced by air pressure into the receiver, after which the "pyridine base" is added.

The denaturing solution is distributed in drums, sealed by the revenue authorities and bearing labels certifying that the mixture is in accordance with law. The drums are received by the consignee can only be unsealed by a revenue officer. A running account is then kept on an official label on each drum of the successive quantities drawn for denaturing purposes.

SECTION 8.

Artificial Silk Factory.

By the courtesy of Dr. Bottler, whom we met in Berlin, and who is managing director of an artificial silk factory at Jülich, near Cologne, we were enabled to pay a visit to that establishment.

In the process followed in this case alcohol plays a very important part, seeing that something like a gallon and a half of proof spirit is required, either in the form of ether or of spirit, to produce 1 lb. of the finished product.

The process is as follows:

Nitro-cellulose is dissolved in a mixture of ether and alcohol, consisting of sixty parts of ether and forty of alcohol, and the solution thus obtained, which is in effect colloidion, is after filtration driven under pressure until it finally emerges, through a number of fine glass tubes. On contact with the air the solution solidifies and the threads thus formed are picked up on bobbins, sixteen of the primary threads being immediately twisted into a single thread which becomes the unit for further operations.

The ether used in the factory is purchased from outside, not manufactured on the spot.

The alcohol comes in under Excise seal in the usual way, and is denatured in accordance with the regulations by being mixed with 10 per cent. of ether. The denaturing is carried out in the presence of the revenue officers and under their supervision. The denatured spirit is stored in a metal tank, under revenue lock and fitted with an indicator outside showing the quantity present in it.

Copper-zinc vessels are used, in preference to iron, to avoid injury to the ethered alcohol from corrosion.

From the tank the denatured spirit, when required for use, passes through closed pipes to the vessel in which the nitro-cellulose is dissolved—the additional ether required being added at this point. While in the dissolving chamber the spirit is not accessible to the workmen employed in the factory; and speaking generally we should say that the conditions of this manufacture lend themselves to the establishment, without much cost or difficulty, of an effective control over the spirit employed.

We may mention that Dr. Bottler informed us that very great difficulties had been met with in perfecting the process of manufacture, and that although the factory had been in operation for over two years, it was only within the ten days preceding our visit that he was able to feel confident that all the difficulties had been overcome. Into those difficulties the obligations in respect of denaturing did not enter, and the experience of this factory is sufficient to show that the embarrassments which attended a similar experiment made some years ago at Coventry, and which were there attributed to the character of the methylated spirit that the promoters were compelled to use, may arise from more causes than one.

SECTION 9.

Production and Price of Spirit in Germany.

The production of spirit in Germany is a state-aided enterprise, of which the primary purpose is not so much the production of spirit on economic lines as the encouragement of agriculture in the less fertile provinces of the Empire, which lie on its Eastern frontiers, and in which the conditions of soil and climate are so unfavourable that without some such encouragement the country would be in serious danger of depopulation.

To enter into the history and details of the system, interesting though they be, would be to go beyond the province of our inquiry. We shall, therefore, confine our attention as closely as we can to the two points which are of interest to our Committee, viz.: the effect of the system on the price of spirit for industrial purposes and its effect upon the price of spirit for export.

The system is essentially communal in character, and its effects can be better seen by studying its results broadly and as a whole, rather than by attempting to trace its influence upon the interests of individuals.

Looking at it from this point of view, it may be said that the fundamental principle of the scheme is to make those interested in the production of alcohol sharers with

the State in the revenue collected on spirit used for potable purposes.

Thus in the year ended on 30th September, 1903, there was collected from the taxes on spirit a total sum of 10,000,000*l.*, out of which a sum of 3,100,000*l.* was given back to persons interested in the trade. But of this sum of 3,100,000*l.*, apparently some 700,000*l.* had been already levied as tax on the producers, so that their net subvention would be 2,400,000*l.* In the same year the total production of spirit in Germany was in round figures 132,000,000 proof galls., and accordingly the State subvention in that year represented a bonus of nearly 4*½*d. per proof gall. on all the spirit produced. The figures must, of course, vary from year to year, according to the circumstances of production and consumption; but probably not very widely.

The question for us is whether this bounty, be it 4*½*d. per gall. or more or less, is retained by the producers or distributors, or whether it goes, in whole or in part, to cheapen spirit to the consumers.

Our conclusion is that as a rule it is retained by the producers in respect of all spirit consumed in Germany, and that only under certain circumstances do the German users of spirit secure a share in it.

We will endeavour shortly to give the grounds on which we form this conclusion.

The system of subvention, as established in Germany, stimulates production, but at the same time it provides within itself an arrest of the stimulus after a certain measure of production has been reached. For the *maximum* bounty that can be secured in respect of any spirit, and which may be put at about 1*½*d. per proof gall., is obtainable only in respect of a certain limited output, called the *contingent*. The total of such output is the equivalent of the amount of spirit estimated to be required for consumption as drink;—and therefore of the amount of spirit on which alone tax will be ultimately levied; and the contingent of each distiller is the share annually allotted to him of such amount. On that share it is possible, in favourable circumstances, for a distiller to obtain the maximum bounty of 1*½*d. the proof gall. But as soon as his production exceeds this allotted contingent, one portion of the bounty, representing about 6*½*d. per proof gall., automatically ceases, and on the excess production the distiller can at most obtain 5*½*d. per proof gall. Only the smallest distilleries can obtain the maximum bounty of this kind; and as a distillery increases in size and output the bounty diminishes until with the larger distilleries it becomes non-existent. Thus the system of subvention gradually ceases to operate as a stimulant to production, and it may perhaps be said that the system gives no encouragement to produce more than such an amount of spirit as is sufficient to satisfy the demand for consumption for all purposes within the protected German market, and to provide a moderate margin for stock.

The distribution of spirit produced in the German Empire is practically a monopoly of an association called the *Centrale für Spiritus Verwertung*, which is representative of the producers of spirit, and which acts as intermediary between them and the consumers, for 90 per cent. of all the spirit produced. The policy of this association coincides with the Governmental policy in tending to restriction of production within the limits above indicated, and in so far as this policy is successful it is clear that, with practically prohibitive duties on the importation of spirit, the user of spirit in Germany is not likely to be able to secure for himself any portion of the benefit of the State bounties. He may only do so to a limited extent, when the general policy of the State and of the association is defeated by unforeseen variations either in the supply or in the demand of any period.

With the spirit exported the case is somewhat different. For this must frequently represent a surplus of which the association desires to relieve the home market; and it may be assumed with some confidence that, in order to get rid of such surplus, a price is in the circumstances usually accepted which represents a transfer to the purchaser of a part, or even of the whole, of the State bounty.

Another feature of the system in its bearing upon the price of spirit to German users is this, that it tends to great

fluctuations of price. For the general principle of the system being to limit production relatively to consumption, no safeguard is provided against the contingency that has arisen this year of a shortage in production due to a failure of that which provides four-fifths of the material used in distilling, *viz.*: the potato crop.

Thus our conclusion is that the German user of spirit is not generally benefited by the state-aid given to production of spirit, and at times is injured by it.

The evidence of facts seems to support these theoretical deductions. At the present moment, as we were informed by a large user of spirit, the price charged for spirit of first quality, such as is necessary for the finer purposes which spirit is used, is, free of all duty, 50 marks per hectolitre—at the German standard of pure alcohol. A British standard of proof spirit this is approximately to 50s. per 38 proof galls., or a little over 1s. 3*½*d. per proof gall. The price of similar spirit of British manufacture in the United Kingdom is about 10*½*d. per proof gall. Three years ago the minimum price for spirit was in Germany, 7*½*d. per proof gall., and the average price for the year 1902 was 8*½*d. In the United Kingdom the price of British spirit was the same as now. The 1902 was, however, altogether an exceptional year for Germany, and manufacturers have little expectation of seeing similar prices recur, unless, as one gentleman told us, the *Centrale* Association should be dissolved and competition between producers introduced.

Moreover, in 1902 the *Centrale* was pursuing the policy of endeavouring to cheapen spirit for industrial purposes by charging higher prices for spirit used for consumption as drink, and lower for industrial spirit. This policy, however, broken down, in consequence, we surmise, of a tendency noticeable in Germany, as it is in this country, to a decrease in consumption of spirituous liquors in consequence of contracts made for long terms of years; the policy is still in operation in respect of spirit used for industrial locomotives and other engines. But as the contracts expire, it is anticipated that the policy will be modified, if not abandoned, even in this category of consumption.

It will be seen from the above figures that at the present time the price of industrial spirit in Germany is substantially higher than it is in the United Kingdom; the price is subject to violent fluctuations; and that although at times it has been and probably will again be appreciably below the British price, it is doubtful whether its normal level in future will show any very material advantage to the German user.

As regards the cost of denaturing by special agents, it is hardly possible to name an average figure. In all cases the cost of manipulation, of attendance of Excise officers, of vessels and instruments, has to be borne by the manufacturer, and one manufacturer estimated for us as at least 2 marks per hectolitre, or about 1*½*d. per bulk gall. of strong spirit. In addition there is the cost of the denaturing agent, which varies very much, according to the substance used. Our informant estimated that in his case the average of the whole cost of denaturing might be taken at 7 marks per hectolitre of strong spirit, or about 1*½*d. per bulk gall. We are inclined to think this is a high estimate seeing that the cost of "complete" denaturing is definitely known to be only a little more than 1*½*d. the bulk gall. In that case, however, there is the economy that results from simplicity, regularity, and magnitude in the operations.

A question that pressed itself strongly upon our attention during our visit to Germany, was how far the consumption of spirit for domestic and industrial purposes in this country could be taken as a measure of the possible consumption for similar purposes in the United Kingdom, and we think it may be useful that we should offer to the Committee some observations upon it.

In the year to 30th September, 1903, the consumption in Germany was—

	proof galls
For domestic use	(about) 33,000,000
For motor and other engines	1,100,000
For industrial purposes	14,000,000
Total	48,000,000

the year to 31st March, 1903, the consumption in United Kingdom for similar purposes was—

or domestic use	(about)	2,200,000
or industrial use	"	3,300,000
Total		5,500,000

At first sight these figures suggest somewhat startling possibilities. But, if the facts be examined, it will be found that the possibilities of extended use of spirit in the United Kingdom are not very moderate dimensions. In the first place the large consumption of spirit in the United Kingdom is for heating, cooking, and lighting, and is due not to the absolute cheapness of spirit, or to any special advantage that it possesses as an agent for heating and light, but is due solely to its cheapness compared with other agents, coal, gas, or oil. In the United Kingdom it is the agent that most directly competes with spirit, and in Germany oil, in the interests of alcohol, is subjected to a duty of 3 marks per cwt., or nearly 21d. per cwt. In the United Kingdom its importation is consequently the comparison stands thus:

	Price of Methylated Spirit per bulk gall.	Petroleum per gall.
many	1s. 0d. (normal)	10½d.
	1s. 9½d. (present)	
United Kingdom	2s. to 2s. 6d.	5d. to 7d.

The price given above for petroleum in Germany is much higher than in the United Kingdom, and there it is cheaper than spirit. In the United Kingdom spirit, which has to compete with oil as well as with coal, is very little used for domestic purposes; probably not more so than in this country. In rural districts oil is probably dearer than in Berlin, more difficult to procure, whereas methylated spirit is of universal distribution (it enjoys preferential rail-rates)—and of uniform price, and it is therefore in the United Kingdom with cheap gas and cheap oil, no doubt a reduction in the price of methylated spirit will make spirit able to compete with them in price. It is not always the determining motive of choice of mass of the people. For though spirit has certain advantages in directions other than price, they are not of marked significance in themselves, nor are they of a character to appeal very powerfully to the masses. Accordingly we may dismiss almost entirely the use of spirit for domestic purposes as offering an opening for extension in the demand for spirit in the United Kingdom.

As regards spirit for industrial purposes the case is different. Even here a large abatement must be made from the figures before they can be taken as a possible measure of British consumption. Of the 14,000,000 proof gallons used in 1902—3, 6,350,000 galls. were employed for vinegar-making, which, as we show elsewhere, is not present, or likely to be present in the United Kingdom. Another 2,650,000 galls. is used for polishes, shes, &c., an industry which in this country enjoys special advantages and which may be supposed to have reached a pretty full measure of development, which it employs some 1,800,000 galls. of spirit. This leaves some 5,000,000 proof galls. used in Germany for miscellaneous industrial purposes, for which in this country we use some 1,500,000 proof galls.

From these figures one may say that the increased demand might arise for spirit in this country, in consequence of extension in its use for industrial purposes, may be placed at less than 3,500,000 proof galls.

Outline of German Spirit Taxes and Rebates.

Alcohol manufactured in the German Customs Union is subject to the following taxes:—

A Consumption Tax (Verbrauchsabgabe).—A certain amount of alcohol (about 4.5 litres) per head was granted, and this was with certain modifications divided amongst distillers in proportion to the make for previous years. The distillers are allowed to sell the quantity allotted to them subject to a charge of 50 M per hecto-

litre. Anything over their fixed quantity is subject to a charge of 70 M per hectolitre.

(2) **(a) Tax on Wash (Mischbottelssteuer).**—Paid by agricultural distillers. This amounts to 1.31 marks for each hectolitre content of their washback. If the distiller gets about 8.2 per cent. alcohol from his wash this would correspond to a tax of 16 marks per hectolitre, and this is the amount of the drawback allowed on exportation, denaturation, or for manufacturers' use for this tax. As a fact the distiller gets far more alcohol from his wash than this, and the average yield in 1900-1 was 10.8 per cent., so that if the average distiller paid 1.31 M per hectolitre of washback content, he only paid 12.13 M per hectolitre of alcohol and was reimbursed 16 M on export, which shows a bounty on export of 3.87 marks per hectolitre. In the case of a great number of distillers, the tax is modified very much, and some only pay six-tenths of the tax, i.e., 7.27 marks showing a bounty of 8.7 marks per hectolitre, and if his yield is above the average the bounty will be still higher. The "Zeitschrift für Spiritusindustrie," the official Journal of the German Distillers' Association, describes a yield of 11.21 per cent. of spirit from the wash as a good but not brilliant yield, and taking this as a basis it corresponds to a tax of 11.68 marks per hectolitre of alcohol, and six-tenths of this is equal to 7.008 M per hectolitre paid, as against 16 M repaid on denaturation or exportation, corresponding to a bounty of about 9 M per hectolitre.

(b) **Taxation Materials (Brennstoffmaterialsteuer).**—Paid by distillers on certain materials (such as fruit, wine, beer, etc.) and varies with the material instead of the tax on wash. This tax varies with the materials. In the case of certain distillers only four-tenths of the full tax is charged.

(c) **Addition to Consumption Tax (Zuschlag zur Verbrauchsabgabe).**—In all manufacturing distilleries and also in some agricultural distilleries and material distilleries instead of the wash tax or material tax, a tax of 20 marks per hectolitre is charged, but this is reduced in some cases to 8 marks per hectolitre.

(3) **A Distillation Tax (Brennstoffsteuer).**—This varies from nothing to 6.5 marks per hectolitre according to the distillery, but on export, denaturation, or manufacturers' use, the full 6 marks is allowed, and so constitutes an additional bounty.

The bounty obtainable from the tax on wash amounts to	d.
9 M per hectolitre	2.7 per proof gall.
And the bounty obtainable from the distillation tax amounts to 6 M per hectolitre	1.8 ..
Or together to	4.5 ..

In addition to the fact that a distiller is allowed to make a certain amount of alcohol at 20 marks per hectolitre less than the normal duty, constitutes a further benefit; and the distiller may, if he wishes, actually receive this amount of 20 marks per hectolitre allotted quantity in the shape of Government Bills or Warrants. This is equivalent to a benefit of 6d. per proof gall. on spirit made up to the allotted quantity.

The possible benefits are:—

(1) Bounty from tax on wash ..	d.
(2) Bounty from distillation tax	2.7 per proof gall.
(3) Benefit from being allowed to make at less than the normal duty	1.8 ..
	6.0 ..
	10.5

This is probably about the maximum that a distiller can obtain, and it is not maintained that all distillers get such large benefits; but the statements published in their own recognised Journals show that the benefits they get are very considerable—in fact, without very large advantages in taxation, it is difficult to see how

the small agricultural distillers could exist at all. The German Spirit Syndicate buy up nearly the whole of the alcohol made, and in order to keep up the price of alcohol

for consumption as a beverage, they sell for export denaturation, and use in arts and manufactures at which they admit they make a heavy loss.

Statement of German Spirit Duties taken for the "Kalender für die Landwirthschaftlichen Gewerbe," 1902-03.

A—Receipts	Marks.		£

1902-03.

B—Rebates	Marks.		£	
			£	s. d.
I. Refund of tax on wash and material	22,179,114		1,085,852	9 1
II. Refund of consumption tax	483,308		23,661	19 1
III. Warrants for duty allowances	36,923,610		1,807,718	8 1
IV. Brennsteuer refund	4,117,705		201,595	19 5
Total of repayments and allowances I—IV	63,703,737		3,118,828	15 9
C. Alcohol from Luxemburg	15		0	14 8
A—B+C	141,079,862		£6,907,034	18 2

These figures show that, out of a total taxation of over £10,000,000, over £3,100,000 are expended in bounties and rebates on duties.

APPENDIX No. I.

DUTIES AND ALLOWANCES ON BRITISH SPIRITS AND DUTIES ON FOREIGN SPIRITS.

The duty (Excise) on British spirits is at present 11s. per gall. at proof.

When British spirits are exported (or used for certain operations in bond), not only is the duty of 11s. remitted, but an allowance also is paid by the Inland Revenue at the rate of 3d. per proof gall. on plain spirits, and of 5d. per proof gall. on compounded spirits.

These allowances are commonly spoken of as the "allowances on British spirits."

The duty (Customs) on Foreign spirit is at present—

On brandy and rum 11s. 4d. per proof gall.

On other sorts 11s. 5d. per proof gall.

(with certain special rates for liqueurs and perfumed spirits and for spirits imported in bottle).

The difference (4d. or 5d. as the case may be) between the duty on British spirits and that on foreign spirits is commonly spoken of as "the surtax on foreign spirits," or more briefly as "the surtax."

Both the allowances and the surtax which date from 1860 (when the old protective duties were done away with), aim at the same purpose, which is, not to put the British producer of spirits in a position of advantage as compared with his foreign or colonial competitor, but to save him from being placed in a position of disadvantage.

In imposing a heavy duty on British spirits, it is necessary at the same time to impose on their manufacture restraints designed to prevent any spirit from escaping the duty. These restraints have the effect of appreciably increasing the cost of manufacture; and in consequence the burden of the duty on the British producer of spirit is not adequately measured by the figure of the duty alone, but must be measured by that figure *plus* the figure by which the cost of manufacture is increased by the Excise restrictions.

Accordingly if we take *x* pence per proof gall. for this latter figure, and 11s. per proof gall. as the duty on British spirit, the full burden of the tax on the producer of British spirit per proof gall. is represented by the expression (11s. + *x* d.).

It follows that, when the producer of British spirit sends out his goods to compete in neutral markets, he is entitled to relief to the extent of 11s. + *x* d. and not of

11s. only, per proof gall.; and conversely that foreign goods should not be admitted to the home market at a less charge than 11s. + *x* d. per proof gall.

The values of *x* have varied from time to time according to the following table:—

	Surtax.			Allowance	
	Rum.	Brandy.	Other Sorts.	Plain Spirits.	Compounded Spirits.
From 1860	2d.	5d.	5d.	2d.	1d.
" 1881	4d.	4d.	4d.	2d.	1d.
" 1902	4d.	4d.	5d.	3d.	1d.

The determination of values for *x* is a matter of extreme difficulty. To arrive at it, it is necessary to take into account—

(a) The tax, if any, on materials of manufacture.

(b) The effect of Excise restrictions on the cost of manufacture.

At the present time (a) is a negligible quantity. For, although there is a tax on sugar and glucose, these materials enter into distillation of spirits to so small an extent that the tax may be left out of account. Molasses used for distilling is duty free.

As regards (b), the Excise restrictions that do, or may, affect the cost of manufacture are numerous, but the principal among them are the following:—

(1.) The prohibition against brewing or distilling simultaneously:

(2.) The prohibition against mixing worts during fermentation:

(3.) Compulsory stoppage of work between Saturday and Monday:

(4.) Restrictions on the manufacture of yeast:

(5.) Separation of distillery and rectifying premises and loss of duty on spirits rectified.

(No. 5 hardly affects the cost of manufacture of "plain spirits.")

From this enumeration of the factors which have to

	1860, Amount claimed by		Amount allowed in 1860.	1860 Considered admissible by this Department	
	Scotch Distillers.	English Distillers		For Un- coloured Spirits.	For Coloured Spirits.
Compensation for duty on foreign grain	d. 0½	d. 0½	d. 0½	d. 0½	d. 0½

ten into account, it will be obvious that anything like accuracy in fixing values for x is unattainable. The manner in which the rates of surtax were originally fixed in 1860 is shown in the following table, which was first published in the Board of Inland Revenue's Tenth Report (1870), and which in the literature of the subject has since been frequently reproduced.

The period that has elapsed since 1860, appreciable changes have taken place in the conditions of manufacture and in the rate of duty on spirit, and a computation of the figures at which the rates of surtax should be based on items and on values that would materially from those shown in the original table. The composition of the rates as they now stand there accepted or authoritative analysis, and all that is said of them is that they represent the outcome, by way of compromise, of prolonged controversy renewed at intervals, as occasion for question presented during a period extending over more than forty

may, however, be convenient to say a few words as to the increase by 1d. of the allowances and of the duty on spirits other than rum and brandy, which was in 1902 at the time when the duty on corn was raised. For the retention of the increase, notwithstanding the repeal of the corn duties in 1903, has been a subject of criticism.

The imposition of the corn duties was the occasion rather than the cause of the addition to the allowances of the surtax.

As, taken by themselves, it was calculated that the increase, as first proposed, would not have warranted an addition than six-tenths of a penny, nor, as finally decided, with a reduced duty on maize, a larger addition than three-tenths of a penny.

For some years prior to 1902 the distillers had been urging on the Treasury and the Board of Inland Revenue that the old rates of allowance and of surtax were insufficient—(notably on the occasion when in March, 1898, a deputation representing the whole trade met on the then Chancellor of the Exchequer)—and the expert officers of the Excise had admitted that could not dispute the arguments in favour of some increase in the rates.

That the amount of increase should be was a matter difficult to determine, and it was still in question whether the revival of the corn duties took place.

At the event made action imperative, and an additional duty was agreed to—the addition, however, not to be added to brandy or rum, which are not made from

when the duties were repealed in 1903 the question was as to an adjustment of the rates of allowance and duty. But as the adjustment could not have exceeded three-tenths of a penny, and as the composition of the duties under the rates was far from precise, it was decided that no change should be made.

APPENDIX II.

REGULATIONS AS REGARDS USE OF SPIRIT FOR INDUSTRIAL, &c., PURPOSES.

(See also this Journal, 1402, 1301 and 1562, and 1903, 270-271.)

UNITED KINGDOM.

The Customs and Excise Taxes on Spirits are :—

Customs—11s. 4d. per proof gall. on rum and brandy; 11s. 5d. per proof gall. on other spirits.

Excise—11s. per proof gall.

DUTY FREE SPIRIT.

ABSTRACT OF THE BRITISH REGULATIONS.

I.—METHYLATED SPIRIT.

There are two kinds of methylated spirit.

A.—“Ordinary” Methylated Spirit for use in manufacturing operations.

This consists of a mixture of 90 parts of ordinary ethylic alcohol of a strength of 60 to 66 o.p. (i.e., containing from 91 to 95 per cent. of real alcohol) and 10 parts of wood naphtha of an approved type.

The official regulations do not require the British or foreign spirit used to be of a greater strength than 50 o.p. (86 per cent. alcohol), and Colonial rum of a strength of only 20 o.p. (69 per cent. alcohol) may be used; but in practice rum is now never methylated, and the spirit is always over 60 o.p. (91 per cent. alcohol).

No duty is paid on British spirits used for making methylated spirit, and foreign and Colonial spirits are exempt from the ordinary spirit tax of 11s. per proof gall.; but foreign spirits have to pay a Customs surtax of 5d. per proof gall., equivalent to about 8d. per gallon on the spirits as actually methylated. The surtax on Colonial rum is 4d. per proof gall., equivalent to about 6½d. per gall., at 60 o.p., or less than 5d. per gall., if rum of 20 o.p. were used for methylating.

Methylated spirit can only be made by :—

1. Distillers.

2. Rectifiers, i.e., persons who redistil duty-paid spirit.

3. Licensed methylators.

In practice methylated spirit is, as a rule, made by methylators, who pay an annual licence of 10l. 10s.

All methylators have to provide suitable mixing rooms, vats, locks, fastenings, and appliances for weighing, measuring, and mixing the spirits and wood naphtha, and the necessary desks for the convenience of the revenue officials who supervise the operations. Mixing vats must be of a capacity of 550 galls., and wood naphtha vats of 100 galls.

Spirits for methylation come from Customs or Excise duty-free warehouse accompanied by official permits, and are received by a supervisor and officer of Inland Revenue, who examine and check the strength and quantity, and see the spirits run into the mixing vats.

To the spirits in the vats is then added one-ninth of its bulk of approved wood naphtha. The contents of the vat have to be thoroughly mixed, and the total quantity and strength again measured by the officials. An official entry of these particulars is made, and the vat and its contents are then handed over to the methylator for disposal in accordance with prescribed regulations. Not less than 500 galls. of methylated spirit must be made at each mixing.

The wood naphtha used for mixing with the spirit must be approved by the Board of Inland Revenue before it is used. For this purpose a sample is drawn from the naphtha vat and sent to the Government Laboratory for examination, the vat itself being locked up by the revenue officer until the principal of the Government Laboratory has certified that the naphtha is fit for methylating purposes. The nature of the examination to which the naphtha is submitted is described in the annexed paper "A," and from this the character of the wood naphtha used for methylating purposes in this country can be gathered.

"Ordinary" or manufacturing methylated spirit can be sold by methylators only to persons authorised by the Board of Inland Revenue to receive this kind of spirit.

A user of this spirit must send to the methylator an official requisition signed by himself, and on which there is a certificate signed by the local supervisor of Inland Revenue that the applicant is authorised to receive such spirit. Less quantities than five galls. cannot be supplied. The methylator has to enter the particulars of every consignment in an official permit taken from a book supplied to him by the supervisor, and this permit must accompany the spirit to the premises of the user, and be delivered to the officer of Inland Revenue when he visits the premises.

When any person wishes to use methylated spirit in any manufacturing process, or for making embrocations, lotions, medicaments or other preparations, written application has to be made to the Board of Inland Revenue. The particular purpose for which the spirit is intended to be used, with some general description of any manufacturing process involved, has to be given, and also a statement of the situation of the premises and of the quantity of spirit likely to be used annually.

After inquiry by the local officials the board issue their authority for the use of the spirit, and instruct their officers to supply the applicant with a book of requisition forms, in order to enable him to obtain a supply of the spirit from a methylator.

Where the quantity of methylated spirit used exceeds 50 galls. per annum, a bond, with one or more sureties in sums of 200*l.* to 1000*l.*, for the due observance of any conditions that may be imposed and the proper use of the spirit, is required. Hospitals, infirmaries, colleges and other public institutions are not usually required to give a bond.

Methylated spirit is not allowed to be used for manufacturing purposes on any premises where ordinary alcoholic beverages are made or sold, nor for the preparation of any article of food or drink, or to be mixed with any medicine capable of being taken internally. With these exceptions methylated spirit may be used in almost any art or manufacture, and is, as a fact, used for a very great variety of manufacturing and technical purposes. For medicinal and pharmaceutical purposes, for instance, the use of methylated spirit has been sanctioned for the extraction, crystallisation and purification of nearly 500 resins, oils, alkaloids, synthetic perfumes and other substances where the finished products contain none of the spirit; for making several hundred embrocations, lotions, liniments and other medicines for outward application; for most veterinary medicines; and for making collodion, flexible collodion, surgical bandages, iodoform, ethyl and methyl chloride and bromide, and other articles used in surgery and medicine.

As a rule the conditions imposed on the users of methylated spirit are very simple, and interfere very little, if at all, with the manufacturing operations. It must not be removed from the premises where its use has been allowed, and the manufacturing operations have to be carried on substantially in the method described in the

application. Any material alteration of the process, those portions of it where the spirit is used, has to be notified to the revenue officials, and the board's sanction obtained for the change, but this is merely for the information of the inspecting officers, and permission for desired alteration is rarely or never refused.

In a great many cases the methylated spirit used in manufacturing operations is wholly or partially recovered and used over and over again. Where this recovery includes redistillation the revenue permission has to be obtained, and in some cases, where the manufacturing operation and the redistillation might so purify portions of the spirit as to render it capable of being fit for potable purposes, special conditions are imposed, such as the collection of the whole of the distillate in receiver and not in fractions, or the immediate mixing of the recovered spirit with fresh methylated spirit, or with some other substance.

As a whole, however, there is very little interference by the revenue officers. Except for periodical inspections, and the occasional sampling of the recovered spirit and of the intermediate and finished products of operations, manufacturers are left to carry out their operations in any way they please, provided they supply the revenue authorities with sufficient information to enable the officers to see where and how the spirit is used.

Neither the methylators nor the manufacturers have to pay anything towards the cost incurred by the revenue authorities in supervising the making, or the use of methylated spirit.

B.—"Mineralised" Methylated Spirit.

This is the methylated spirit which is sold by retailers to the general public for use for burning in spirit lamps, cleaning and domestic purposes generally, and also some extent for mixing with paints, stains, varnishes, and for polishing purposes by cabinet makers, &c.

In making "mineralised" methylated spirit the alcohol is first mixed with the wood naphtha as in making "ordinary" methylated spirit. After mixing with wood naphtha, the whole contents of the vat of "ordinary" methylated spirit, or a portion of the spirit, less than 100 galls., removed to another vat, is furnished with three-eighths of 1 per cent. (0.375 per cent.) of an approved "mineral naphtha." This mineral naphtha is an ordinary light mineral oil having a gravity of from 0.800 to 0.830. The addition of mineral oil does not interfere with the purposes for which this kind of spirit is mainly used, *viz.*: burning in spirit lamps, &c. Its use was introduced some 15 years ago in order to prevent the drinking of the "ordinary" methylated spirit which was found to be going on to a limited extent among certain classes in the poorer districts of Glasgow and other large cities.

Persons who wish to retail "mineralised" methylated spirit must obtain a licence costing 10*s.* annually. A body except distillers and publicans may obtain a licence. Retailers of "mineralised" methylated spirit are furnished with a book of requisition forms to enable them to obtain their supplies of such spirit from methylators.

Methylators are not allowed to sell the spirit to retailers in greater quantities than 50 galls., or in less quantities than five galls., but the smaller retailers are allowed to purchase it in quantities not exceeding a gallon at a time from any other retailer. The stock of "mineralised" methylated spirit which a retailer may keep is limited to 50 galls., and he is not allowed to sell to any person a greater quantity of such spirit than 1 gall. at a time.

Retailers are also prohibited from selling the spirit between ten o'clock on Saturday evening and eight o'clock on the following Monday morning; and, in exceptional cases, they have to keep a stock account of all spirit received and sold, and the names of the persons to whom it is sold. These regulations are for the purpose of preventing the illicit drinking of the spirit which still occasionally occurs in some localities, and are required more for police than revenue purposes.

Anyone may buy "mineralised" methylated spirit from a retailer, and may use it for any purpose except

preparation of beverages or of medicines capable of being taken internally. All attempts to purify or to use the spirit for use for these purposes are also prohibited; and anyone who sells, for use as a beverage or as a medicine, or has in his possession any methylated spirit, or derivative thereof, prepared or purified for such use, is liable to a penalty of 100%.

SPIRITS DENATURED WITH OTHER SUBSTANCES THAN WOOD NAPHTHA.

Under the powers conferred on them by the Spirits Act, 1902, and Section 8 of the Finance Act of 1902, the Commissioners of Inland Revenue have authorised the use of ethyl and methyl alcohol denatured with substances other than wood naphtha to be used in the following manufacturing operations:—

making Coal Tar Dyes.

- a.) Methyl alcohol, mixed with 0.05 per cent. of wood naphtha.
- b.) Ethyl alcohol, mixed with 2.0 per cent. of wood naphtha, or 2.0 per cent. of nitrobenzol.

in the manufacture of Xylonite and similar articles.

Methyl alcohol mixed with—

- a.) One pound of camphor and 1 pint of coal tar naphtha (toluol) per gallon.
- b.) One pint of toluol per gallon.
- c.) One pound of camphor per gallon.
- d.) 0.05 per cent. of bone oil.
- e.) 0.5 per cent. of petroleum ether.

in the manufacture of Fulminates.

Methyl alcohol mixed with 10 per cent. of the spirit distilled from a previous operation, and 0.025 per cent. of bone oil.

in the manufacture of Coconut Oil Refining. (Temporary sanction.)

Methyl alcohol mixed with an equal volume of wood naphtha.

in the use in making Electric Lamps.

Methyl alcohol mixed with one pound of red phosphorus per gallon.

Any substance used in the denaturing operations is, as a rule, one used in the distilling operations involved, and there are special provisions as to the mode of working and supervision by revenue officials, including in some cases the constant presence of one or more Excise officers on the premises open for work. Traders using these specially denatured spirits have to pay the cost of the Revenue excise.

UNDENATURED ALCOHOL is allowed to be used by hospitals, colleges, and other public institutions for teaching and under certain conditions.

THE EXAMINATION OF WOOD NAPHTHAS.

Wood naphtha must be sufficiently impure to be used in the manufacture of spirits, prepared by mixing one part of the wood naphtha with nine parts of spirits of such an amount of nauseousness as will, in the opinion of the Principal of the Government Laboratory, be such a mixture incapable of being used as a beverage, and containing mixed with potable spirits of any kind without being unfit for human consumption.

Wood naphtha submitted for approval should conform with the following tests:—

- a.) Not more than 30 c.c. of the naphtha should be required to decolorise a solution containing 0.5 gm. of bromine.
- b.) The naphtha, which must be neutral or only slightly alkaline to litmus, should require at least 25 c.c. of deci-normal acid to neutralise 25 c.c. of the naphtha when methyl orange is used as the indicator.

It should contain:—

- a.) Not less than 72 per cent. by volume of methyl alcohol.

(b.) Not more than 12 grms. per 100 c.c. of acetone, aldehydes, and higher ketones, estimated as "acetone" by the formation of iodoform according to Messinger's method.

(c.) Not more than 3 grms. per 100 c.c. of esters, estimated as methyl acetate by hydrolysis.

The following details of the manner in which the above tests are conducted in the Government Laboratory are published for the information of the trade:—

Bromine Decolorisation.

A standard bromine solution is made by dissolving 12.406 grms. of potassium bromide and 3.841 grms. of potassium bromate in a litre of recently boiled distilled water.

50 c.c. of this standard solution (=0.5 gm. bromine) are placed in a flask of about 200 c.c. capacity, having a well-ground stopper. To this is added 10 c.c. of dilute sulphuric acid (1 in 4), and the whole shaken gently. After standing for a few minutes the wood naphtha is slowly run from a burette into the clear brown solution of bromine until the latter is completely decolorised. Not more than 30 c.c. of the wood naphtha should be required for this purpose.

Methyl Orange Alkalinity Test.

The naphtha should be faintly acid to phenolphthalein, slightly alkaline or neutral, rarely acid to litmus, and always alkaline to methyl orange. 25 c.c. of the wood naphtha are placed in each of two beakers, and titrated with deci-normal acid, using in the one case a few drops of litmus solution, and in the other of a solution of methyl orange, as indicator. With litmus usually 0.1 to 0.2 c.c. of deci-normal acid is required to neutralise. With methyl orange the total alkalinity should be greater—at least 5 or 6 c.c. of deci-normal acid being required for neutralisation.

The total alkalinity, less that given with litmus, is the "methyl orange alkalinity," and, for the 25 c.c. of wood spirit, should not be less than is required to neutralise 5 c.c. of deci-normal acid.

Estimation of Methyl Alcohol.

Twenty-two grms. of coarsely powdered iodine and 5 c.c. of distilled water are placed in a small flask and cooled by immersion in ice-cold water. Then 5 c.c. of the wood spirit (60.0 o.p.) are added, the flask corked, the contents gently shaken, and allowed to remain in the ice-cold bath for 10–15 minutes.

When well cooled, 2 grms. of red phosphorus are added to the mixture of spirit and iodine in the flask, and the latter is immediately attached to a reflux condenser.

The reaction soon commences, and must be moderated by dipping the flask into a cold water bath. (Spirit may be lost if the reaction is too violent.) After about 15–20 minutes, when all action appears to have ceased, the water bath under the flask is gradually heated to a temperature of about 75° C. (167° F.), and the flask being occasionally shaken is allowed to remain at this temperature for 15–20 minutes. The source of heat is then removed, and the apparatus left for an hour till it has cooled, when the condenser is reversed, and the methyl iodide slowly distilled off—first at a low temperature—the bath being allowed to boil towards the end of the operation only. The end of the condenser dips into water in a measuring tube, and the iodide is collected under water and measured at a temperature of 15.5° C. (60° F.)

The percentage (by volume) is found from the formula:—

$$\frac{\text{c.c. methyl iodide found} \times 0.647 \times 100}{\text{c.c. wood spirit taken} \times \text{vol. of methyl alcohol}} = \text{Percentage (by vol.)}$$

Or when 5 c.c. of spirit are taken:—

$$\frac{\text{c.c. methyl iodide} \times 12.94}{\text{percentage (by vol.)}} = \text{percentage (by vol.)}$$

Esters, acetals, &c., also yield methyl iodide by this process, and from the percentage of methyl alcohol calculated as above, an amount equivalent to the percentage of these substances present must be deducted. Practically, however, methyl acetate is the only com-

pound usually found in quantity sufficient to materially affect the result. The grms. of methyl acetate per 100 c.c. of spirit multiplied by 0.5405 give the equivalent of methyl alcohol to be deducted from the total percentage by volume calculated from the methyl iodide found.

The Acetone Reaction.

Twenty-five c.c. of normal soda are placed in a flask similar to those used in the bromine reaction. To this is added 0.5 c.c. of the naphtha. The mixture is well shaken, and allowed to stand 5—10 minutes. Into it from a burette n/5 iodine solution is run slowly, drop by drop, vigorously shaking all the time till the upper portion of the solution, on standing a minute, becomes quite clear. A few c.c. more of n/5 iodine solution are added, as to get concordant results an excess of at least 25 per cent. of the iodine required must be added. After shaking the mixture is allowed to stand for 10—15 minutes, and then 25 c.c. normal sulphuric acid are added. The excess of iodine is liberated, titrated with n/10 sodium thiosulphate solution and starch, and half the number of c.c. of thiosulphate solution used are deducted from the total number of c.c. of iodine solution used. The difference gives the amount of acetone by weight in the naphtha by the formula:—

c.c. n/5 iodine solution required $\times 0.3876$ = grms. of acetone per 100 c.c. of wood naphtha.

This includes as acetone any aldehydes, &c., capable of yielding iodoform by this reaction.

If the quantity of "acetone" is excessive, a less quantity of the spirit is taken, or 10 c.c. are diluted with 10 c.c.

of methyl alcohol free from acetone, and 0.5 c.c. of the mixture is used.

Estimation of Esters.

Five c.c. of the wood naphtha are run into a silver flask of about 150 c.c. capacity, together with 20 c.c. recently boiled distilled water. Ten c.c. of normal solution are added, the flask securely closed and diluted for at least two hours in a water bath at 100° C. (212° F.). The contents are then washed into a beaker, and titrated with normal acid and phenolphthalein. The difference between the number of c.c. of soda taken and of that required for neutralisation may be calculated as methyl acetate (weight in vol.) from the formula:—

$$\frac{0.074 \times \text{c.c. soda required} \times 100}{\text{c.c. naphtha taken}} = \text{grms. per 100 c.c.}$$

Or if 5 c.c. of spirit are taken as above:—

$$1.48 \times \text{c.c. soda required} = \text{grms. of methyl acetate per 100 c.c. of spirit.}$$

APPENDIX No. II.

B.—ABSTRACT OF THE APPROXIMATE QUANTITIES OF UNMINERALISED METHYLATED SPIRITS USED IN MANUFACTURING OPERATIONS AND FOR OTHER PURPOSES IN THE UNITED KINGDOM DURING THE YEAR ENDED 31ST MARCH, 1901.

(Prepared from information supplied by Superintendents of Inland Revenue to the Government Laboratory in May, 1901.)

Nature of manufacturing operations or other purposes for which the Spirit was used.		Number of Gallons.
1	Making "finish," varnishes, lacquers, stains, paints, enamels, &c.	1,221.
2	Soap manufacture	144.
3	Hat making	121.
4	Celluloid, xylonite, &c.	106.
5	Ether, chloroform and iodoform	97.
6	Fulminates, smokeless powder, and other explosives (including War Office and Admiralty)	48.
7	Preparation of solid medicinal extracts, medicaments, fine chemicals, &c.	39.
8	Dissolving dyes and colours, and for dyeing and cleaning operations, &c.	28.
9	Making photographic plates, emulsions, films, &c.	24.
10	Making linoleum, pegamoid, linacrusta walton, and similar goods	21.
11	Making embrocations, lotions, liniments, cattle and other medicines	16.
12	Making filaments, &c., in the incandescent electric lamp manufacture	14.
13	In piano making	7.
14	In silk, crape and embroidery manufactures, mainly for stiffening	6.
15	In the manufacture of aniline and other dyes and colours	6.
16	In making fireworks	2.
17	Plant washes, insecticides, &c.	1.
18	In the manufacture of rubber	1.
19	For cleaning paint	1.
20	In the manufacture of steel pens	1.
21	Making blacking and leather dressings	4.
22	In "silvering" mirrors, &c.	1.
23	In corset making	1.
24	Making sheep dips	1.
25	Preparing surgical dressings	1.
26	Adjusting hydrometers, and in making compasses, thermometers, and other instruments	1.
27	In oil refining	1.
28	Electrotyping	1.
29	Making inks	1.
30	Various miscellaneous manufactures, &c., engraving, brass founding, watchmaking, china making, printers' rollers, black lead, candle making, artificial silk, artificial flowers, calico printing, cotton yarn, rope, oil gas generators, &c.	1.
31	Preserving specimens in museums, hospitals, infirmaries, &c., for burning in lamps, washes, lotions, and other purposes in hospitals, infirmaries, and similar institutions, and also for laboratories and educational purposes	33.
32	For the War Office and Admiralty requirements, chiefly at Woolwich and dockyards	30.
Total		1,987.

OBSERVATIONS.

The returns from which the abstract has been prepared are in a very condensed form, and do not give in detail the various purposes for which the spirit is used nor the quantities used for each purpose when there are several. In some cases, therefore, it has been necessary to estimate the probable quantities assigned to each head, and the figures must, therefore, be taken as approximate only. In the case of the largest users, however, there is no difficulty. The "ether," "solid medicinal extracts," and "lotions" are the most doubtful, as most makers use the spirit for all three purposes.

On the whole, however, the figures given are probably very nearly correct.

The "quantities" are the quantities received by the year by the users.

The total, 1,987,665 galls., compares with 2,064,514 galls., the estimated quantity of unmineralised nated spirit made during the year, showing a deficiency of 87,849, or a little over 4 per cent., due partly to was partly probably to the imperfections in the returns.

It is not possible to make any separation between "finish" and "varnishes," etc., properly so called, but as "finish" is itself almost entirely used for varnishes, or for thinning or manipulating these

and for polishing purposes, any distinction would be of much value.

mineralised or retail methylated spirit is used for burning in spirit lamps, for cleansing and for purposes generally, and also to some extent for use with paints, stains, varnishes, &c., and for polishing surfaces by cabinet makers, &c.

APPENDIX No. II.

COMPARISON OF THE QUANTITY OF SPIRITS, EITHER USED IN MAKING METHYLATED SPIRITS, AND OF THE METHYLATED SPIRITS PRODUCED, FOR THE FIVE YEARS ENDING 31ST MARCH, 1904.

Year.	Proof Galls. of Spirits delivered for Methylation.		Total.	Average Strength.	Quantity in bulk of Spirits Methyated.	Wood Naphtha used.	Ordinary (Unmineralised) Methyated Spirit for Manufacturing Purposes.	Mineral Naphtha.	Mineralised Methyated Spirit for Retail Sale.	Total.
	British.	Foreign.			Galls.	Galls.	Galls.	Galls.	Galls.	Galls.
1900-1	4,978,027	6,245	4,984,272	63.7	3,043,485	338,165	2,058,450	4,962	1,328,162	3,386,612
1901-2	5,070,713	120,332	5,191,045	64.3	3,158,442	350,938	2,075,514	5,377	1,439,243	3,514,757
1902-3	4,640,770	627,410	5,268,180	64.3	3,206,214	356,246	2,157,127	5,270	1,410,603	3,567,730
1903-4	4,230,688	1,210,001	5,451,689	64.9	3,305,502	367,278	2,213,580	5,472	1,464,672	3,678,252
1904-5	5,054,586	334,140	5,388,726*	63.5	3,295,485	366,165	2,139,784*	5,707	1,527,573	3,667,357

The decrease in 1903-4 is mainly due to the fact that certain firms, e.g., the British Xylonite Company, Nobels, and Leitch and Co., have been allowed the use of duty-free alcohol denatured by other substances than wood naphtha. The total quantity so allowed in 1903-4 was 206,452 proof galls., which would be 125,885 bulk galls. at 64° o.p. (93.5 per cent. alcohol).

APPENDIX No. III.

REGULATIONS AS REGARDS USE OF SPIRIT FOR INDUSTRIAL PURPOSES IN GERMANY.

TAXES ON SPIRITS.

Spirit taxes in Germany are levied in so many different ways that it is difficult to arrive at any very accurate estimate of the average rate.

Imported spirits of all kinds, including arrack, rum, brandy, and mixed spirits :—

Liqueurs	240 marks
All other Spirits—	
(a) In casks	160 ..
(b) In bottles, flasks, and other vessels	
240 marks for every 100 kilos.	
(220 lbs.), i.e., from about 7½ d.	
to 1s. 1d. per lb.	

The tax has apparently to be paid on the gross weight and contents, and no satisfactory comparison with the British system can, therefore, be made. From 10s. per proof gall. may be taken as an approximate estimate according to the character of the spirit and the vessels containing it.

At Hamburg, Cuxhaven, Bremerhaven, and Gestemünde and other places, are not included in the Spirit Tax and spirits coming from these "free cities" into other parts of the German Empire have to pay the same taxes.

Each distillery is allowed to produce a certain fixed quantity of spirit annually, called "the contingent," which is paid a "consumption tax" ("verbrauchsteuer") of 50 marks per hectolitre of pure alcohol. On excess production over the "contingent" 70 marks per hectolitre is charged.

The "contingent" may be increased or decreased for various reasons at any time, and there is a general revision every five years.

Various other taxes are also levied. For these, German spirits are divided into three classes :—

1. *Industrial Distilleries* ("Gewerbliche Brennereien") on by individuals or companies solely for manu-

facturing purposes. These distillers have to pay per hectolitre of pure alcohol in addition to the "consumption tax"

(a) an "addition" (Zuschlag) of from 16 to 20 marks.

(b) a "distilling tax" (Brennststeuer) of from 2 to 6½ marks.

Distilleries producing not more than 200 hectolitres of pure alcohol annually (7,700 proof galls.) are exempt from the "distilling tax," and the smaller distilleries pay the lower rates according to the fixed scales.

2. *"Agricultural Distilleries"* (Landwirtschaftliche Brennereien) are those using as raw materials potatoes

or grain grown on the owners' farms, or on the farms of one or more of the owners, if the distillery belongs to a society or company. These pay modified "additions" of from 10 to 20 marks per hectolitre of pure alcohol and are exempt from the "distilling tax," or pay only from 1 to 3 marks per hectolitre; or instead of these taxes they may elect to pay a "fermenting vat tax" (Maischbottichsteuer), of from 0.786 mark to 1.31 mark per hectolitre on the fermenting vat capacity for each fermentation.

3. *"Material Distilleries"* (Materialbrennereien) are those using berries, fruits, wine lees, grape pressings, etc.

These appear to be all very small, many of them making no more than 11 to 22 galls. of alcohol annually. In addition to the "consumption tax" of 50 marks, they pay from 0.10 to 0.85 mark per hectolitre of material used.

The total average tax on spirits produced in "Industrial Distilleries" is estimated at not more than 70 marks per hectolitre of pure alcohol, equivalent to about 1s. 9d. per proof gall., and in the "Agricultural Distilleries" at somewhat less—60 to 65 marks per hectolitre—or about 1s. 7d. to 1s. 8d. per proof gall. By far the greater proportion of the spirit made in Germany is produced by the "Agricultural Distilleries."

DUTY FREE ALCOHOL.

ABSTRACT OF THE GERMAN REGULATIONS.

Spirit for employment in industrial operations, vinegar making, cleaning, heating, cooking or lighting, as well as for educational or scientific purposes, may, after having been denatured according to the regulations, or in special cases without denaturing, on proof of the spirit having been so used, be granted freedom from the spirit taxes on the following conditions :—

The freedom from duty includes—

(a.) The release from the "consumption" tax and its "additions."

(b.) The refunding of the "fermenting vat" tax at the rate of 0.16 marks per litre of pure alcohol so far as the spirit has been subjected to it.

(c.) The return of the "distilling" tax at the rate of 0.06 marks per litre of pure alcohol.

Duty paid spirit and spirit containing more than 1 per cent. of fusel oil are not admitted for denaturing.

The denaturing is either *complete*, i.e., such as is deemed sufficient to make the spirit undrinkable, or *incomplete*, i.e., such as requires the employment of other means for the prevention of the improper employment of such spirit.

General denaturing agent for complete denaturing:

- 1 part of wood naphtha, and
- 1 part pyridine bases,

to each litre of which may be added 50 grms. of lavender oil or rosemary oil.

Of this mixture 2½ litres are added to each hectolitre of alcohol.

(German methylated spirit therefore contains 2 per cent. wood naphtha, and 0.5 per cent. pyridine bases, with optionally 0.125 per cent. of a lavender or rosemary oil.)

The mixing of the general denaturing substance can only be carried out by persons who have obtained special authority for the purpose from the chief Inland Revenue Office of the district where the mixing establishments are situated. Authorised methylators have to provide rooms and vessels for storing and mixing the denaturing agents, all materials and implements necessary, and to give the officials the requisite assistance in sampling the denaturing substances and in the mixing them with the spirit. They have also to provide books of an official pattern for entering the particulars of the mixings and of the sale and transport of the denatured spirit.

The denaturing may take place in special vats erected for the purpose, or in the casks or other vessels used to transport the alcohol. Not less than a hectolitre (22 galls.) of alcohol can be denatured at a time. Before denaturing the alcoholic strength and quantity of spirit in each vessel is checked by the Excise officer, unless such spirit has been sent in vessels under special revenue seals, and which are found intact on examination. The wood naphtha and pyridine bases used for denaturing must first be examined and approved by official chemists, samples being taken for this purpose from the vessels used for storing these materials, which remain under revenue control from the time the sample is taken until mixed with the spirit. The store vessels must contain not less than 100 litres (22 galls.) of the denaturing agents when sampled. The Excise officers are directed to see that the denaturing materials are thoroughly mixed with the spirit.

The nature of the official examination of the wood naphtha is described in the official directions printed on page 256 from which the character of the substance used can be gathered. As compared with the British type of denaturing wood naphtha the German wood naphtha is of a more impure character, i.e., it contains a much larger proportion of acetone, and other substances, and less methyl alcohol.

The pyridine bases are used mainly to increase the nauseous character of the methylated spirit, and serve practically the same purpose as the mineral naphtha used in the United Kingdom and in France.

For use in motor-cars and other internal combustion engines, etc., alcohol may also be completely denatured by the addition of 1½ litres of the "general" denaturing agent and ½ litre of a solution of Methyl Violet dye, together with from 2 to 20 litres of benzol to every 100 litres of alcohol.

The ordinary completely denatured spirit and the motor-car spirit may be sold by persons who are authorised to do so by the Administration. Written application for a licence has to be made to the superior Excise official, who may exercise his discretion as to whether a licence should be given, and the licence may be withdrawn at any time if it appears advisable to disallow the sale in any particular shop. Before obtaining a licence notification must be given to the police.

The ordinary completely denatured spirit is intended for sale by retail, and may be used for any industrial purpose; for cleansing, heating, lighting, and cooking, as well as for educational and medicinal purposes; but must not be present in any substance intended for human

consumption, and no attempt must be made to rectify such spirit, or to add anything to it to disguise its taste or smell, nor must it be diluted under 85° (49° F.). Heavy penalties are imposed for any contravention of the regulations.

The general control of the retail sale of the denatured spirit is very similar to that imposed in this country the police appear to be more directly concerned in preventing irregularities than with us.

For general use on a large scale for industrial manufacturing processes of all kinds, what is called "wood spirit denatured" alcohol is allowed to be sold under special conditions. This denatured consists of a mixture of 100 litres of alcohol of not less than 90° (58 a.p.) with 5 litres of wood naphtha.

The denaturing of this spirit may take place either at the works where it is to be used, or on the premises of authorised methylators. In the latter case the regulations as to mixing, storing, etc., are the same as in the case of the completely denatured spirit. Permissible to sell this "wood spirit denatured" alcohol can only be granted by the chief office, and makers who sell "wood spirit denatured" alcohol have to keep an official "Control Book" in which has to be entered particulars of all spirit denatured, and of every sale of such spirit. A balance is struck annually and duty is charged on any material loss or deficiency that may be shown; satisfactory explanations can be given. Such spirit can only be sold to factories which can show a licence to buy "wood spirit denatured" alcohol. Any person wishing to obtain a "buying licence" must apply to the chief office of the province in which the factory in which such spirit is to be used is situated. Full particulars of the purposes for which the spirit is required must be given. No person engaged in the spirit trade, or who sells denatured or undenatured spirit can obtain a licence; a licence may be refused if any facts are known which render the use of denatured spirit in any factory undesirable. A licence is only given for one year, and maximum quantity allowed cannot be exceeded without special authority. The "buying licence" must be renewed each time any methylated spirit is purchased. The seller must enter on the licence the quantity sold, adding his name and the date, and must also enter the sale in an official "Control Book." Not less than 2 (½ galls.) may be sold at a time, and the seller must show that the maximum annual quantity shown on the "buying licence" has not already been supplied to the buyer.

The buyer must enter every purchase in a "Control Book" kept at the works. From these entries in the "Control Books" the buying and selling accounts are checked and the annual quantities allowed at each factory are fixed.

The denatured spirit must be stored in a special compartment at the factory, and on each occasion that any of it is removed for use in the works an entry of the quantity and particular purpose for which it is to be used must be made in the "Control Book" and a note must also be entered of the pages of the factory work books and of the official business books in which particulars are to be entered of the production, storage, and sale of the denatured substances in the manufacture of which the methylated spirit has been used.

On the demand of the superior officers of the Administration these books and business books must be produced for their inspection.

Where this "wood naphtha denatured" alcohol, or the "completely denatured" alcohol is unsuitable for any particular manufacture, special denaturing agents may be allowed. Denaturing with special reagents can only be made at the factories where the alcohol is produced, and permission must first be obtained from the chief office of the province for the use of such spirit.

All the special substances sanctioned for denaturing purposes have to be tested by an official chemist according to officially described methods, and the users of denatured spirit have to pay for the analyses as well as to provide the denaturing substances, and proper vessels, etc., for keeping and mixing the approved reagents with the alcohol.

The mixing takes place in the presence of officials

quantities of each kind of specially denatured alcohol to be entered in a separate opening of the "Control Book" kept in separate vessels or compartments at the premises, and used under conditions applicable to the "naphtha denatured" alcohol already described. A regular account of the amount of all denatured spirit on hand at the premises of the users of such spirit is to be taken at least once a year. The entries in the "Control Book" of spirit received and used are to be checked, and a report of the comparison submitted to the chief office, in fulfilment of duty on any loss of spirit shown by the account imposed, but only when there is reason to believe that spirit has been used in illegal ways. Denatured spirit may be recovered in any manufacturing process, but permission must first be obtained. The recovered spirit may be used again for the same purpose for which it was previously used. If used for other purposes, or if it is purified, it has to be again denatured, and treated as fresh denatured spirit. If used from repeated denaturing samples are to be sent for examination, at the cost of the user, by an official in order to determine whether it remains unfit for consumption. Recovered spirit may have to be stored in specially sealed vessels till again denatured. Incomplete denatured spirit must not be removed from the premises.

For incomplete denaturing the following substances (denaturing agents) may be used. They are to be used for denaturing purposes in the undernoted quantities per 100 litres of the spirit.

a.) For industrial uses of all kinds:—
5 litres of wood spirit,

or 0.5 " pyridine bases.

b.) For the production of brewers' varnish and similar substances:—

20 litres of a shellac solution, which is made by adding 1 part by weight of shellac in 2 parts by weight of spirit of at least 90° (58 o.p.), are added to the spirit.

In this case the alcohol in the shellac solution if made under official supervision is also allowed exemption from duty.

c.) For the production of celluloid and pegamoid:—

1 kilo. of camphor,
or 2 litres of turpentine,
or $\frac{1}{2}$ " benzol.

d.) For the production of the following substances:—

1. Ether, ordinary (with certain limitations and regulations as to sale and use).

2. Ethyl sulphuric salts.

3. Agaricin, Podophyllin, Scammony, Gniagum and Jalap resins, as well as other resins and gum resins.

4. Aldehyde and paraldehyde.

5. White lead and acetate of lead.

6. Ethyl chloride, bromide and iodide.

7. Photographic paper and dry plates, and emulsions of chloride, bromide and iodide of silver and gelatin, and similar preparations.

8. Chloral hydrate.

9. Electrodes for electric storage batteries.

10. Acetic ether (with certain limitations as to sale and use).

11. Glucosides.

12. Rubber preparations.

13. Collodion and bromide, chloride and iodide of silver emulsions of collodion.

14. Pancreatin, alkaloids, santonin, tannin, and salicylic acid and its salts.

15. Coal tar colours, including substances used in obtaining them, and intermediate products.

16. Chemical preparations (not otherwise named) which do not retain any spirit when finished (except formic ether, valerianic ether and butyric ether):—

10 litres of sulphuric ether,
or 1 litre of benzol,
or $\frac{1}{2}$ " turpentine,
or 0.025 " animal oil.

Collodion for sale must contain at least 1/100th of its weight of gun-cotton.

(e) For the preparation of chloroform,
300 grms. of chloroform.

(f.) For the production of vinegar.

200 litres vinegar containing 3 per cent. acetic acid,
or 150 " " " 4 " " "
or 100 " " " 6 " " "
and 100 litres of water.

and so on.

or 50 litres vinegar containing 12 per cent. acetic acid
and 100 litres of water.

or 30 " " " 6 per cent. acetic acid
and 70 litres of water,
and 100 " " "

Any excess of the quantity of acetic acid in the vinegar mixture or of the spirit are to be allowed for, and the water may be replaced entirely or in part by an equal quantity of beer, glattwasser, or natural wine.

(g.) For making inks, sealing wax, and stamping inks:—

0.5 litre of turpentine,
or 0.025 litre of animal oil.

(h.) For making bedstead enamels, and brewers' varnish, as well as for use in incandescent lamps, for finishing silk ribbons, and for cleansing jewellery, etc.
0.5 litre of turpentine.

(i.) For making iodoform,
200 grms. iodoform.

The iodoform may be dissolved in part of the spirit, and the solution then added to the remainder of the spirit.

(k.) For varnishes and polishes of all kinds:—
2 litres of wood spirit and 2 litres petroleum benzol,
0.5 litre of turpentine.

Polishes and varnishes not for use in the works of the makers, but for sale, must contain at least 1/10th part of their weight of shellac or other resin.

(l.) For preparing medical, botanical and zoological preparations for educational purposes:—
1 litre (commercially pure) methyl alcohol
and 1 litre petroleum benzol.

(m.) Soap-making.

1 kilo. of castor oil and 100 c.c. of soda solution.

The denaturing materials may be dissolved by heating in part of the spirit, and the solution then added to the remainder of the spirit.

(n.) For the production of wool fat (lanoline):—
5 litres of petroleum benzol.

Spirit is only allowed duty free for the production of ether and acetic ether under the proviso that they are (under official control) either exported; or else used at home for industrial uses; or for the purpose of testing in scientific and technical trades or professions; or for the production of materials for surgical bandages, but not for ether-containing medicines; or for making fulminates, smokeless powders, and other munitions of war; or for use in certain public institutions. So far as the ether and

acetic ether are not used by the maker, but are sent to other workshops, or to the named institutions and factories, the regulations as to obtaining a licence for buying, selling and using, as well as to the keeping of a control book by the sellers, are the same as in the case of "wood naphtha denatured" spirit.

It will be required also that the buyers, by means of their business and manufacturing books, or by special books, shall enter the particulars of the use of the ether and acetic ether.

A buyer's licence for ether made from duty free spirit can also be given if the ether is to be exported by the buyer, or is to be sent to an authorised industrial user, institution or factory. The intermediate merchant in these cases is under the same control as the maker of ether for sale. The superintending officers can permit ether makers to change ether, which has been made from duty free spirit into taxed ether, so that it may be used or sold for the uses excepted in paragraph 1.

In this case the ether is to be notified for taxing, its weight officially taken, and the proper duty, on the basis of 1.6 litre of alcohol for each kilo. of ether, is to be assessed. If the spirit used is subject to any other charges the highest charge is to be taken.

More particular regulations are made by the chief office.

The denaturing of spirit with 0.5 litre of turpentine for cleaning bijouterie, and for making polishes and lacquer varnishes which are to be used for lead pencils, toys, and clock-making can also be permitted in the existing districts of the Chief Imperial Finance Ministry even when the spirit is not to be used in the factory of the applicant, but is to be sent to other factories. The regulations as to the sale and use of "turpentine denatured spirit" are the same as for "wood naphtha denatured" spirit.

PURE DUTY FREE ALCOHOL.

Pure alcohol without denaturing may be delivered duty free—

(a) *To certain Hospitals, Lying-in Hospitals, and Lunatic Asylums, as well as to Public Scientific Institutions.*

Permission has first to be obtained from the chief office of the province, and an application must be made in writing stating the purposes for which the spirit is to be used, and the extreme annual quantity required. The quantities allowed are fixed by the chief office and revised every three years. Not less than 25 litres (5½ galls.) can be received at a time. A stock book has to be kept by some specially designated official of the institution, in which is to be entered particulars of the receipt and use of the spirit. The spirit may be used only inside these institutions for general scientific and heating purposes, and it makes no difference whether the spirit is directly used for the specified purposes or only indirectly so used, e.g., to clean instruments, to disinfect the operators or operating tables, or for heating inhalation apparatus, etc.

Otherwise, the spirit can only be used for the purposes stated. It is specially forbidden to give the spirit to other persons, or to take it outside the institutions except by special permission of the chief office. Duty free ether and acetic ether are allowed in the institutions under similar regulations.

(b) *For making smokeless powders, fuses, and fulminates, as well as for making the varnishes used in finishing these substances.*

Permission has to be obtained and the same regulations as are applicable to the buying, storage, and use of "wood naphtha denatured" spirit, and the keeping of "control books" and other accounts are enforced. At large works stock is taken at frequent intervals, and there is generally a somewhat more stringent supervision by the Excise officers. Permission may be granted for recovery of any spirit used in the manufacturing operations. The spirit must only be used *inside* the factories and must not under any circumstances be removed from the works. Duty may be charged on any unexplained loss or deficiency

shown at the stock takings. Duty free ether and ether are allowed in these factories under similar regulations.

Pure undenatured alcohol was formerly allowed used by apothecaries, medicine makers, druggists, and veterinary surgeons for the preparation of 80 tinctures, spirits and liquors according to the formulae of the German pharmacopoeia and other authentic formulae, and also for doctors' prescriptions in making bandages, etc. This privilege was withdrawn in October, 1902, and all medicines have now to be prepared with duty paid spirit.

No foreign spirit of any kind, nor any mixture containing spirit, or substances made from spirit, are allowed to be used duty free in Germany. All imported alcohol, alcoholic mixtures and derivatives have to pay the Customs duties before being delivered for use.

INSTRUCTIONS FOR TESTING WOOD NAPHTHA

1. *Colour.* This shall not be darker than that of a solution made by dissolving 2 c.c. of n/10 iodine in 10 c.c. of distilled water.

2. *Boiling Point.* 100 c.c. placed in a short-copper flask of about 180–200 c.c. capacity is placed on an asbestos plate having a circular hole of 30 mm. diameter. Into the neck of this flask is placed a fractionating tube 12 mm. wide, and 170 mm. long, with its tube connected to a Liebig's condenser at least 400 mm. long. In the fractionating tube, which is provided with a bulb about a centimetre blow the side tube, is placed an officially tested thermometer with a scale ranging from 0° C. to 200° C., so that its mercury bulb is in the middle of the bulb. The flask is heated so that the distillation proceeds at about the rate of 5 c.c. per minute. The distillate is collected in a cylinder graduated in c.c. and at 75° C. with a normal barometric pressure of 760 mm. at least 90 c.c. shall be collected. If the barometer is not at 760 mm. during the distillation 1° C. shall be added for every variation of 30 mm., e.g., at 770 mm. 9 c.c. shall distill at 75° C.; and at 750 mm. 90 c.c. at 75° C.

3. *Miscibility with water.* 20 c.c. wood spirit mixed with 40 c.c. water shall give a clear, or only slightly opalescent solution.

4. *Acetone Content.*

(a) *Separation on mixing with soda solution.*

20 c.c. of wood spirit are shaken with 40 c.c. of a soda solution of S.G. 1.300. At least 5 c.c. of wood spirit must separate after standing for half an hour.

(b) *Titration.*

1 c.c. of a mixture of 10 c.c. of wood spirit with 90 c.c. of water, is mixed with 10 c.c. of double normal soda solution. Then 50 c.c. of n/10 iodine solution is added with continual shaking, and the mixture allowed to remain at least for three minutes. Then excess of sulphuric acid is added, and the excess of iodine titrated with n/10 hypo and starch solution. At least 22 c.c. of n/10 iodine solution shall be required for the acetone.

5. *Bromine Absorption.* 100 c.c. of a solution of KBrO_3 and KBr (made up as under) are acidified with addition of 20 c.c. of dilute H_2SO_4 (S.G. 1.290). To this mixture the spirit is added drop by drop from a burette so long as any colour remains on shaking. The addition shall be so arranged that in one minute 10 c.c. of spirit shall be added. Not more than 30 c.c. shall be required for decoloration, and not less than 20 c.c. This test shall be done in full daylight, and the temperature shall not exceed 20° C.

Bromine Solution.

After at least two hours' drying at 100° C., and cooling in an exsiccator, 2.447 grms. of KBrO_3 and 8.719 grms. of KBr of tested purity are dissolved in water, and the solution made up to 1 litre.

The subjoined tables show, for the three years ending 30th September, 1903, (a) the quantities of duty free spirits issued for use in Germany, (b) the quantities of pure undenatured of the several methods allowed, and (c) the quantities used for particular manufactures, etc.

(A) Quantities of Duty-free Spirit issued during

Year ending 30th Sept.	Completely Denatured.	Incompletely Denatured.	Undenatured.	Total.	Completely Denatured.	Incompletely Denatured.	Undenatured.	Total.
	Hectolitres of Pure Alcohol.				Equivalent bulk Galls. of Pure Alcohol.			
1901	782,295	339,754	33,820	1,155,869	17,210,490	7,474,588	744,040	25,429,118
1902	704,729	345,894	59,427	1,110,050	15,504,038	7,609,668	1,307,391*	24,421,100
1903	900,190	360,730	17,792	1,278,712	19,804,180	7,936,060	391,424*	28,131,664

The use of undenatured duty-free spirit in the preparation of medicinal tinctures and prescriptions was formerly allowed in any. This privilege was withdrawn after the 30th September, 1902. Undenatured alcohol is now only allowed to be used duty-free in certain hospitals, asylums, and public scientific institutions, for making smokeless powders, &c., mainly in Government factories. The sudden increase from 33,820 hectolitres in 1901 to 59,427 hectolitres in 1902 was probably connected with the publication of an order of the Government to disallow the use of pure duty-free spirits for medicinal purposes, this intention being published at an advance of the time that it was to take effect.

Methods of denaturing and quantities of Alcohol denatured in the years ending 30th September, 1901, 1902 and 1903.

APPENDIX No. IV.

REGULATIONS AS REGARDS USE OF SPIRIT FOR INDUSTRIAL &c. PURPOSES IN FRANCE.

The Customs and Excise taxes on alcohol are as follows:—

Customs (Importation)—70 francs per hectolitre (equivalent to about 1s. 5d. per proof gall.) and 80 centimes per hectolitre (equivalent to about 1s. 7d. per 100 proof galls.) for control, &c.

These duties are in addition to the Excise duty.

Excise (Internal)—220 francs per hectolitre of pure alcohol (equivalent to about 4s. 6d. per proof gall.)

DUTY FREE SPIRIT

ABSTRACT OF FRENCH REGULATIONS.

Spirits for industrial and domestic use are free from all taxes on condition that they are denatured, but all medicaments which contain any spirit after their manufacture pay the ordinary spirit duty. Denatured alcohol pays a statistical tax of 0.25 franc per hectolitre of pure alcohol (about 7d. per 100 proof galls.) and also 0.50 franc per hectolitre (about 1s. 10d. per 100 proof galls.) to cover the expense of the examination of the samples and the supervision of the denaturing operations.

Any person who desires to denature spirit must submit a plan of his premises and supply details as to the vessels, &c., and the materials to be used for denaturing.

Denaturing takes place in presence of the Excise officials. The alcohol must be of at least 90° (58 o.p.) and contain not more than 1 per cent. of "fused oil."

Samples of both the alcohol and of the denaturing substance to be used have to be submitted to analysis as directed by the Ministry of Finance, and all operations are supervised by the Excise officials.

Spirits may be denatured by the "general process" or by "special processes."

Denaturing by the "special" processes is usually carried out at the factories where the spirit is to be used.

General Denaturing Process.

Ten litres of wood spirit of at least 90° (58 o.p.) and containing 25 per cent. acetone and 2.5 per cent. of "impurities pyroxylics" for 100 litres of spirit.

Spirit denatured by this reagent is divided into two classes:—

1. *For lighting and heating and for making "finish"*—This spirit must contain, in addition to the general denaturing agent, 0.5 per cent. of heavy benzine, distilling between 150° and 200° C., when used for heating and lighting, and 4 per cent. gum resin for "finish."

These spirits are allowed to be sold, under strict regulations and police and Excise supervision, both wholesale and by retail to the general public, and correspond to our mineralised, methylated spirit and "finish." Since 1st January, 1902, there is allotted to the makers of denatured alcohol for heating, lighting, and motive power a sum of 9 francs per hectolitre of pure alcohol (about 21d. per proof gall.). This is to reduce the cost of denaturing for the various uses to which this alcohol is applied in competition with petrol.

2. *For Manufacturing purposes*, such as "varnishes, solid extracts, solidified spirits, plastic substances, alkaloids, fulminate of mercury, transparent soap, insecticides, &c."

Manufacturers wishing to use this spirit must obtain permission. They have to keep an account of spirits received and used, and of the nature and quantity of the products manufactured by its aid.

Excise officers frequently visit the works in order to assure themselves that the products made correspond to the spirit produced.

If the products contain any alcohol they come under the same regulations as to sale, &c., as methylated spirits.

This spirit corresponds to our "ordinary unmineralised

methylated spirit," and the regulations in France are not less but more stringent than in this country.

3. Certain industries cannot use methylated spirit mixed with wood spirit, and the Ministry have authorised the employment of other processes of denaturing specially adapted to the particular necessities of each manufacturer. These are either *special* for each product, or have to be approved by the Minister, or *general* for products or classes of products already approved on the report of the Consultative Committee.

Of the latter are:—

1. *Ethers, simple and compound.*

Alcohol is mixed with 10 per cent. of the ether (of a fixed type) of a previous operation, and 1 per cent. sulphuric acid at 66° B., or 20 per cent. at 100° B. The mixture is heated to a temperature of 80° for some time (prolongé) in presence of the Excise officials.

2. *Ethyl Bromide.*

Seven litres of spirit at 93° with 8½ litres sulphuric acid at 66° and 15 grms. bromine.

3. *Ethyl Iodide.*

6 litres of alcohol at 96°, 4 kilos. iodine, and 10 grms. amorphous phosphorus.

4. *Ethylate of Soda.*

8 litres absolute alcohol and 500 grms. soda.

5. *Nitric Ether.*

1 part nitric acid at 36° and 4 parts alcohol at 96°.

6. *Ethyl Chloride.*

1 part hydrochloric acid at 21° and 1 part alcohol at 96°.

7. *Aldehyde.*

Mix alcohol with 10 per cent. sulphuric acid at 66° or 20 per cent. at 54° B., and heat the mixture to a temperature of 80° C. Cool and then pour the mixture on to bichromate of potash.

8. *Chloroform.*

Mix the alcohol with 5 or 6 kilos. of chloride of calcium in solution.

9. *Collodion.*

Equal volumes of ether and alcohol, and add 100 parts cotton. The mixture should represent 2 litres for each litre of alcohol, and should contain 6 grms. pyroxylin.

10. *Chloral and Chloral Hydrate.*

A current of chlorine gas is passed through alcohol. Each litre of alcohol of 95° ought to produce 750 grms. of chloral hydrate.

In all these cases, as well as in those in which the manufacturer is permitted to employ other special processes, the denaturing has to be done in the presence of an official (Agent d'Administration), and the manufacturer has to keep registers of the alcohol used, and of the products made, and to submit to visits from the officials in the case of those who use the common methylated spirits.

The Administration furnishes the denaturing agent, spirit, &c., at the expense of the makers.

The minimum quantity of spirit that can be denatured by the general formula is 20 hectolitres (440 galls.), and by any special formula 10 hectolitres (220 galls.).

In all the "special cases" the French regulations appear to involve the presence of an official during at least the initial stages of every manufacturing operation, in addition a detailed return from the manufacturer of the quantity of the products he obtains and of the spirit used, and the officials have to be satisfied that the correspondence between the spirit used and the products obtained is satisfactory. Manufacturers are charged with duty on any deficiency of spirit shown by the returns or inspections.

There appears to be no provision in France for remission of the Import (Customs) duty on spirits, and no foreign spirit is denatured.

Showing the Quantities of Denatured Spirit used in France for various Manufacturing Purposes during the years 1900-1-2-3.

These spirits, as well as a large proportion of that classed under "chemical preparations" and "explosives," contain 10 per cent of wood naphtha.
 From January 1st, 1902, a drawback of 9 francs per hectolitre (about 2½d. per proof gall.) has been allowed on alcohol used for heating and to compensate for cost of methylating, and to enable this spirit to compete with petrol in motor cars, &c.
 There was some alteration of the classification of "drugs," "ether," &c., in 1903.

APPENDIX No. V.

REGULATIONS AS REGARDS USE OF SPIRIT FOR INDUSTRIAL ETC., PURPOSES IN SWITZERLAND.

Customs and Excise Duties.

In Switzerland, the manufacture, importation, and primary sale of alcohol is a monopoly of the Federal Government.

Producers are permitted to distill small quantities of alcohol from grapes, wine, wine-lees, wine yeast, fruits, &c., etc., grown on their own lands; but, with this exception, all kinds of distilleries have to work under the supervision of the officials of the Federal Alcohol Department, and all the spirit produced is taken over by this department at prices fixed by agreement made between distillers and the Federal Finance Minister.

Customs Import Taxes. Brandy, liqueurs, essences, tinctures, and other special alcoholic liquors are imported by private persons on payment of an import duty of 80 francs per 100 kilos, gross weight of the liquid and vessels, where the strength does not exceed 10° a.p., and 80 centimes for each degree over that (equivalent to about 2s. 6d. to 3s. 6d. per proof

gallon). All ordinary alcohol, and substances containing alcohol, come under the monopoly, and can only be imported into Switzerland by the Federal Alcohol Department.

Excise (Monopoly) Taxes.—All imported alcohol, and all Swiss manufactured alcohol, has to be sent to the warehouses of the Alcohol Department of the Federal Government.

Anyone who wishes to buy spirit must order it from the department in quantities of not less than 150 litres. Prices charged are fixed by law at not less than 120 francs or more than 150 francs per hectolitre of alcohol.

The present ordinary "monopoly" prices are as follows:—

(a.) Wein Spirit, mark A.V.W., or Kahlbaum spirit (Fein Spirit from Kahlbaum, Berlin).
 142-60 francs per hectolitre at 95° (5s. 2d. per all. at 66 o.p., 3s. 1½d. per proof gall.).

(b.) Prima Spirit, mark A.V.P.
 140-97 francs per hectolitre at 95° (5s. 1d. per all. at 66 o.p., 3s. 1d. per proof gall.).

(c.) Fein Spirit, mark A.V.F.
 138-53 francs per hectolitre at 95° (5s. per gall. at 66 o.p., 3s. per proof gall.).

(d.) Raw Potato Spirit, mark A.V.P.
 131-24 francs per hectolitre at 90° (4s. 9d. per all. at 58 o.p., 3s. per proof gall.).

From these prices the Government profit or tax is equivalent to about 2s. to 2s. 3d. per proof gall.

Wholesale dealing in spirit or spirituous liquors is not subject to any further licences or taxes, but the retail sale and the regulation of public houses, etc., is under the control of the Cantonal Authorities, who may impose further taxes or licences.

DUTY FREE SPIRIT.

Abstract of the Swiss Regulations.

The Alcohol Department are authorised to sell denatured spirits in quantities of not less than 150 litres (33 galls.) at cost price for the following purposes:—

(a.) For cleansing, heating, cooking, lighting, as well as for use in motor engines.

(b.) For industrial purposes generally, except the preparation of beverages, or of liquid perfumes and cosmetics.

(c.) For making vinegar.

(d.) For scientific purposes.

(e.) For preparing pharmaceutical products which do not contain any alcohol in their finished condition, and are not mixed with alcohol when used.

The denaturing is either "absolute," *i.e.*, such as is considered sufficient of itself to render the spirit unfit for consumption as a beverage; or it is "relative," *i.e.*, such as requires official supervision in order to prevent such relatively denatured spirit being used for other purposes than those for which it is allowed.

"Absolutely" Denatured Spirit. The preparation of "absolutely" denatured spirit is exclusively reserved for the Alcohol Department, who prepare it and sell it to users and retailers in quantities of not less than 150 litres at a time, at a price of 50 francs per 100 kilos, at 93° (about 1s. 6d. per gall. at 63 o.p.). On quantities of 10,000 kilos, sent out at one time in boiler tanks a discount of 2 per cent. is allowed of this price, and from 1½ to 1 per cent. when quantities of 10,000 kilos, and 5,000 kilos, are so sent out in large and small casks.

The methods of denaturing and the substances used are regulated by the Alcohol Department.

The "absolutely" denatured spirit is used for cleansing, heating, cooking, lighting, and motor engines, and for sale, by retail. The retail sale is under the control of the Cantonal Authorities.

For "absolutely" denatured spirit the composition of the denaturing mixture is not kept constant, but for various reasons it is changed two or three times per annum. At present (November, 1901) the Department employ a mixture having the following composition:—

Acetone Oil	700 parts.
Pyridine Bases	100 ..
Solvent Naphtha	90 ..
Crude Wood Naphtha	110 ..
1,000 parts.			

2.7 kilos. of this mixture are added to any 100 kilos. of alcohol at 95° (about 2.7 galls. to 100 galls. of alcohol at 66 o.p.).

This proportion has been kept constant for some time, but cannot be considered as unalterable.

"Relatively" denatured spirit. For all manufacturing purposes, "relatively" denatured spirit is allowed to be used.

Whoever wishes to use this kind of spirit in his business must make application to the Alcohol Department on a special form.

Persons whose names are not registered in the "Trade List" have to obtain an official certificate as to the character of their establishments, and the kind of business carried on by them. The discretion as to the granting of permission is vested in the director of the Alcohol Department, who also determines what bonds or guarantees are sufficient to prevent the improper use of such spirit.

Persons who have been allowed to use this spirit must commence operations within three months of the date of their obtaining the permission, otherwise a fresh application has to be made.

Denaturing may take place either in the warehouses of the Alcohol Department or at the premises of the users of such spirit. In the latter case the users of "relatively" denatured spirit have to obtain the pure spirit from the Alcohol Department, and have then to provide the denaturing materials at their own cost and also premises for mixing the denaturing substances with the spirit in the presence of the officials of the Department.

The officials decide whether the denaturing substances provided comply with the regulations, and if they are not satisfied samples are taken and sent for examination by the technical chemists of the department at Berne. Traders have also to provide the denaturing substances used at a warehouse.

The following substances have been sanctioned for "relative" denaturing in the undernoted proportions for every 100 litres of alcohol for use for the purposes specified:

(a.) *For making Vinegar.*

Five litres of absolute acetic acid dissolved in at least 200 litres of water. The water may be replaced by an equal quantity of beer, wine, yeast, yeast pressings, or similar liquids.

(b.) *For preparing Lacquers, Varnishes, and Polishes.*

2 litres of wood spirit and 2 litres of petroleum benzol,
or, $\frac{1}{2}$ litre of turpentine,
or, 5 litres of wood spirit,
or, 2 kilos. of shellac,
or, 2 kilos. of copal or resin,
or, $\frac{1}{2}$ kilo. of camphor.

The denaturing with camphor will only be allowed to authorised users, who mix varnishes or polishes exclusively for use in their own workshops.

(c.) *For preparing Dye Substances.*

10 litres sulphuric ether,
or, 1 litre benzol,
or, 1 litre coal tar oil,
or, $\frac{1}{2}$ litre turpentine,
or, 25 grms. animal oil, and
or, 25 grms. aniline blue or eosin, violet or fluorescein,
or, 100 grms. naphthalene,
or, 2 kilos. commercially pure methyl alcohol,
or, $\frac{1}{2}$ kilo. camphor.

For the use of other denaturing substances for purposes special permission has to be obtained from the Federal Council.

In the case of (b.) varnishes, etc., and (c.) dye Alcohol Department determines, in each case in which permission is granted for the use of "relatively" denatured spirit, which of the different denaturing substances given in the list shall be used.

The authorised users of "relatively" denatured spirit are required (so far as may not be in whole or in part compensated with) to keep prescribed books in which to be entered the receipt and use of the spirit; the production and disposal of the products made with it; and particulars of any sale of the spirit which may be allowed.

They have also to send to the Alcohol Department immediately after the close of every quarter, extracts of these books, giving full particulars of business done during the preceding quarter, and verified by signature for the accuracy of these reports.

Officials of the department may at any time inspect the stock of denatured spirit, and the quality used, and of the products made with it; and may take samples, and inspect any of the business books belonging to the factory.

The trader and his servants must assist the officials of the department and of the customs in carrying out denaturing, and generally in the exercise of their supervisory functions.

Information must also be immediately given to the officials when there has been any unusual disturbance in the manufacturing operations, or any occurrence which has caused an unusually loss of "relatively" denatured spirit, or of the products made from it.

If more than 10,000 kilos. of relatively denatured spirit are used annually at any factory, iron or otherwise, with gauge glasses and scales or floats, and means of official locking must be provided for storing the spirit.

Manufacturers who use both "relatively" and "absolutely" denatured spirit, and also undenatured spirit in their works, have to keep separate the processes in each kind of spirit is used.

No distilling or rectifying apparatus must be used without the special permission of the department in the rooms in which "relatively" denatured spirit is being used, or in any adjoining room belonging to the authorised user.

If permission has been given to recover the spirit it must be used again for the same purpose, and quantities recovered must be entered in the stock books. The permission for the use of the spirit may be withdrawn at any time, and the withdrawal gives no person any claim for compensation. If by death or any other change in the firm occurs, a renewal of the permission must be obtained from the department by the successor.

When for more than a year no "relatively" denatured spirit has been used, the user must resign his permission and sell or give over to some other authorised user unused spirit, or return it to the Alcohol Department who will pay the market price for it.

The owner of the "relatively" denatured spirit must not sell it, or allow it to leave his manufacturing premises. Permission is given to sell such spirit denatured with-

(a.) 5 litres of wood naphtha,
or (b.) 3 litres of acetone oils,
or (c.) 2 kilos. of shellac, per hectolitre.

Such spirit cannot, however, be sold or given to any person who means to sell it again, but only to use it in their own workshops. Not less than 5 kilos. of such spirit can be sold at a time, and if the person to whom it is sold does not hold a special permission for it, the total quantity he can receive annually must not exceed 150 litres (33 galls.).

Denatured spirit must not be used for any other purposes than those for which permission is given, and particularly it must not be used in any way for beverages, and no attempt must be made to make it wholly or partially from such spirit any of the denaturing substances, or to add other substances which would

the taste or smell of the denaturing substance. Must users of "relatively" denatured spirit in preference with it articles for sale make so slight a change in spirit that it practically remains only denatured.

In particular all varnishes, etc., must contain at least 1 per cent. of their weight of shellac or similar resin. The sale of lacquers, varnishes, and polishes containing 6 per cent. of shellac is free. Dealers in all other articles containing denatured spirit must obtain permission from the Alcohol Department.

Heavy penalties may be imposed for any breach of laws or regulations.

Prices at which authorised users of "relatively" denatured alcohol can obtain their spirit from the Alcohol Department are fixed for periods of five years, according to average prices paid by the department for spirit during the preceding five years.

Present prices per 100 kilos, net at 95° are as follows:—

(a.) Sekunda-Sprit	47.00 francs, about 1s. 4½d. per gall. at 66 o.p.)
(b.) Fein-Sprit or Rohspiritus	48.50 .. about 1s. 5d. per gall. at 66 o.p.)
(c.) Prima-Sprit	51.50 .. about 1s. 6d. per gall. at 66 o.p.)
(d.) Kahlbaum-Sprit or Wein-Sprit	53.50 .. about 1s. 7d. per gall. at 66 o.p.)

the same discounts are given for large orders as in the case of "absolutely" denatured spirit.

An authorised user has to bear the cost of the carriage of the denaturing substances in addition. Until 1904 authorised users were permitted to buy their own spirit from abroad and to import it through the Department on payment of an import duty of 8 francs per 100 kilos (about 2½d. per gall.). In future all alcohol must be imported from the Federal Alcohol Department, and prices for the year 1905 have been fixed as follows:—

(a.) Sekunda-Sprit at 41.0 francs per 100 kilos, net at 95°.
(1s. 2½d. per gall. at 66 o.p.=8½d. per proof gall.)
(b.) Fein Spirit or Rohspiritus at 42.50 francs per 100 kilos, net at 95°.
(1s. 3d. per gall. at 66 o.p.=9d. per proof gall.)
(c.) Prima-Sprit at 45.50 francs per 100 kilos, net at 95°.
(1s. 4d. per gall. at 66 o.p.=9½d. per proof gall.)
(d.) Wein-Sprit at 47.50 francs per 100 kilos, net at 95°.
(1s. 5d. per gall. at 66 o.p.=10½d. per proof gall.)

authorised users who order at one time one or more orders of about 10,000 kilos, net content (2,700 galls.) are granted a discount of 5 per cent. off these prices if they give the Alcohol Department a period of 30 days for execution of their order when foreign kinds of spirit are required.

For all other large orders of over 5,000 kilos, gross weight the usual official discount will be given.

The annexed tables give the quantities of the "absolutely" denatured spirit, and of the different kinds of "relatively" denatured spirit used in 1903, and also the principal purposes for which the latter spirit was used.

Quantity of Denatured Spirit of all kinds sold in 1903.

APPENDIX No. VI.

REGULATIONS AS REGARDS USE OF SPIRIT FOR INDUSTRIAL, ETC., PURPOSES IN AUSTRO-HUNGARY, RUSSIA, HOLLAND, UNITED STATES, BELGIUM.

AUSTRO-HUNGARY.

The Spirit taxes in Austria and Hungary are:—

Customs (Import).—

On liqueurs, punch essence, sweetened spirits, arrack, rum, French brandy and cognac:—150 kronen (rL.) per 100 kilos, equivalent to about 4s. per bulk gall.

On all other spirits.—110 kronen (4l. 8s.) per 100 kilos, equivalent to about 3s. 3d. per bulk gall.

These duties are in addition to the highest Excise duty payable in the country on spirits of the same description.

Excise.—

Austria.—90 kronen (75s.) per 100 litres pure alcohol, equivalent to 1s. 11d. per proof gall.

Hungary.—100 kronen (83s. 4d.) per 100 litres of pure alcohol, equivalent to 2s. 2d. per proof gall.

DUTY FREE SPIRIT.

Ordinary Methylated Spirit is made by mixing with alcohol of at least 90° (58 o.p.)

2 per cent. wood naphtha,

$\frac{1}{2}$ per cent. pyridine bases, and a trace of phenolphthalein.

A tax equivalent to about one-third of a penny per gall. is charged for denaturing.

For Varnishes, fulminate of mercury, hat-making, etc., $\frac{1}{2}$ per cent. of turpentine is the denaturing agent.

For Vinegar the spirit is mixed with "anhydride."

Very small quantities of pure alcohol are used for scientific purposes under certain conditions free of duty.

RUSSIA.

CUSTOMS AND EXCISE DUTIES ON ALCOHOL.

Customs (Import)—16 roubles 20 copecks per pound, equivalent to 34s. 6d. per 36 lbs. As in Germany, probably the weight of the vessels is included, and no very exact comparison can be made with the British standard. Approximately, the tax may be taken at 10s. to 12s. per proof gall.

Excise.—The sale of alcohol is a monopoly in Russia, and distillers have to hand over their produce at fixed rates.

DUTY FREE SPIRIT.

Abstract of Russian Regulations.

Persons wishing to use spirit duty free must apply to the Minister of Finance. Permission is generally limited to *one year*. Security for the duty (bond) must be given.

The quantity of spirit allowed is determined each year, and "depends on the productive power of the manufactory, conditions for disposal of manufactured article, scale of annual consumption of spirit," etc. The spirit is issued from distilleries, rectifying works, etc., on production of the order of the Finance Minister. It is received and examined at the factories by Excise officers, and after *having been denatured*, is placed under revenue seal in a special store and is only issued as required by an Excise officer. Accounts of receipt and issue are strictly kept, and sent to auditing authorities at the end of each year.

As a general rule a special Excise controller is attached to each works for constant supervision of the proper use of the duty free spirit, and the proprietor of the works is bound to provide him with proper dwelling accommodation and with furniture and fuel.

Foreign spirits cannot be imported duty free.

Denaturing processes employed:—

1. *For Varnishes and Polishes.*

100 parts spirit are mixed with 5 parts wood naphtha and 1 part of turpentine, or instead of turpentine shellac, tar, etc., may be used in the proportion of $\frac{1}{2}$ lb. to one vedro (2.7 galls. of spirit).

2. *For the preparation of Wine Vinegar.*

The spirit is diluted with water and vinegar, and it shall be of a strength of 12° tralles (79 u.p.) contain 1 per cent. of acetic acid.

3. *For the preparation of Ether, Chloroform, Hydrate and Iodine.*

20 "lots" of animal oil to 100 vedros (270 galls.) of spirit.

4. *For the preparation of Tannin and Collodion.*

To 100 parts of spirit 10 parts of sulphuric acid are added.

5. *For the preparation of Santonine.*

Fresh spirit is mixed with spirit that has already been used in the proportion of 4 parts of fresh spirit to 1 of used spirit, or 36 lbs. (1 pound) of crude santonine mixed with (10 vedros) 27 galls. of spirit.

6. *For the preparation of Phenacetin, Salol, Salipyr, Salicylic-Nitro Salts.*

5 per cent. of benzol is added to the spirit.

7. *For the preparation of Aniline Dyes.*

5 parts of wood naphtha to 100 parts of spirit, the spirit is mixed with animal oil in the proportion of 20 lots of oil to one vedro of spirit (2.7 galls.)

8. *For the preparation of Artificial Silk.*

10 per cent. of sulphuric ether is added to the spirit.

9. *For the preparation of Resinite or Ksylite.*

7 per cent. of ether or acetone.

10. *For Smokeless Powder Manufacture.*

Spirit is not denatured, but there is strict registration and personal supervision of the Excise officer.

11. *For Fulminate of Mercury.*

$\frac{1}{40}$ th of 1 per cent. of animal oil (0.025 per cent.) and 5 per cent. of the crude recovered spirit is added in the process.

12. *For the Emulsive process, i.e., Extraction of Sugar from Treacle.*

Fresh spirit is mixed with the spirit that has already been used, in the proportion of 1 part of fresh spirit to 1 part of used spirit.

13. *For preventing Freezing of Gas Pipes.*

5 parts of wood naphtha and 1 part of pyridine to 100 of spirits.

14. *For Street Lighting in Towns.*

20 parts of turpentine to 100 parts of spirit; issued to contractors to town councils, etc.

HOLLAND.

The Spirit Taxes in Holland are:—

Excise—63 florins per hectolitre of alcohol at 50°, equivalent to about 5s. 6d. per proof gall.

Customs (import)—A surtax of 3.50 florins per hectolitre of alcohol at 50°, and in addition the Excise tax of 63 florins = total 66.50 florins, equivalent to about 5s. 9d. per proof gall.

DUTY FREE ALCOHOL.

ABSTRACT OF THE DUTCH REGULATIONS.

Ordinary Methylated Spirits.

1 litre wood spirit.

8 litres alcohol of at least 85° (49 o.p.).

This spirit is free to all who like to use it, on condition that it is not used in articles of human consumption, and that no attempt is made to purify it from methyl alcohol.

r Making.

1 hectolitre of alcohol at 50° is denatured with
1 hectolitre vinegar of 4 per cent. strength.
2 hectolitres water.

20 litres vinegar of 4 per cent.
20 litres dried raisin juice.

20 litres vinegar alone if Excise officers see the
ixture added to acidifying vessels.

ission to receive methylated spirits must be
every year.

l spirit provided by Government at a fixed price
cost of methylating.

e keep accounts of quantity used. Vinegar
furnish returns of vinegar made.

mens in spirit for teaching natural history may be
duty free, and no Excise duty is charged.

gn-made varnishes containing wood naphtha
home-made may be imported duty free.

Duties on	fl.
oral hydrate	1.30 per kilo.
er sulphuric	2.20 " "
er acetic	1.20 " "
lodon	1.90 " "
oroform	1.50 " "
rous ether	1.30 " "
ad spirit	1.15 " litre.

1) exempt when required for use in making smokeless
and glazing porcelain.

2) exempt when required for use in making smokeless
and glazing porcelain.

3) exempt when required for incandescent mantles.

4) similar products pay the same surtax and Excise
res of alcohol at 50°.

UNITED STATES.

Customs and Excise duties on Alcohol in the
States are:—

Customs—1.75 dol. (minimum reciprocity tariff).
5 dols. (general tariff).

Per American proof gall.; equivalent to 10s.
to 12s. 10d. per British proof gall.

Excise—1.10 dol. per American proof gall.;
equivalent to 6s. 3d. per British proof gall.

DUTY FREE ALCOHOL.

There appears to be nothing equivalent to British
methylated spirit or denatured spirit of any kind in the
United States.

The only duty free alcohol of any kind is that which
is supplied in very small quantities to certain schools
and colleges for use in education and research.

BELGIUM.

The Customs and Excise taxes on Alcohol in Belgium
are:—

Customs (importation)—

175 francs per hectolitre at 50°, and 3.50 francs
for each degree over 50 for ordinary spirits in bulk
(equivalent to 7s. per proof gall.).

In bottles 350 francs per hectolitre. Other
alcoholic liqueurs at 350 francs per hectolitre.

Food preparations preserved in alcohol, 175 francs
per 100 kilos.

Wood spirit, methyl and amyllic alcohol, and all
homologues pay customs duty.

Excise (internal)—

Excise on home-made spirits is 150 francs per
hectolitre at 50° (equivalent to 6s. per proof gall.).

Agricultural distilleries obtain a rebate of the
Excise duty, equal to 8 to 10 francs per hectolitre
at 50° (equivalent to 4d. to 5d. per proof gall.).

DUTY FREE ALCOHOL.

ABSTRACT OF THE BELGIAN REGULATIONS.

Since 1896, alcohol has been allowed duty free in a few
manufactures, and in a number of others a proportion of
the duty is returned after the alcohol has been mixed
with certain denaturing agents.

Manufacture, &c.	Denaturing Agent used per hectolitre of Alcohol at 04° or over (64 o.p.).	Duty remitted per hectolitre at 50°. (Excise Duty 150 francs.)
	300 litres of water, and 100 litres of vinegar containing 8 per cent. acetic acid <i>For use in workshops where made.</i> —8 litres methyl alcohol (wood spirit) containing 5 per cent. acetone and 25 litres of varnish containing 30 per cent. gum resin <i>For sale.</i> —10 litres wood spirit containing 5 per cent. acetone, and 25 litres varnish containing 30 per cent. gum resin	Francs. 120
colours	10 litres wood spirit containing 5 per cent. acetone, and 25 grms. fuchsin or other aniline colour	114
	10 litres wood spirit containing 5 per cent. acetone, and 25 litres varnish con- taining 30 per cent. gum resin	140
flowers	10 litres wood spirit containing 5 per cent. acetone, and 15 grms. aniline colours	140
gilding	20 litres wood spirit containing 5 per cent. acetone, or 3 litres ethyl methyl ketone	114
materials	10 litres wood spirit and 5 kilos. gum acerride	140
and washing raw oils	10 litres sulphuric acid at 66° B	140
rent soap	5 litres ess. of lavender, aspic of citronella	140
fulminate	10 litres of crude ethers, recovered in process	140
a for use in workshop	50 litres common ether	140
re made	50 litres common ether	140
ds, &c.	5 litres acetone, or 2 litres ethyl methyl ketone, or 25 litres ether	140
ss powder	3 litres ethyl methyl ketone	140
s from brewing yeasts	3 litres ethyl methyl ketone	150
line, a disinfectant	3 litres ethyl methyl ketone	140
ics and medicaments	3 litres ethyl methyl ketone	150
ne yellow	3 litres acetone oil	140
de ficelles	4 litres acetone oil	150
l silk	150 litres common ether	140
g metals	3 litres of mixture of equal parts of ethyl methyl ketone and acetone oil	150
ther	15 litres of acetic ether residues	150
ic or common ether	10 litres of sulphuric ether residues	150
ical, &c., preparations in		
erior schools	500 grms. nitrobenzol, 500 grms. camphor, or 1½ litres ethyl methyl ketone	140

Duty free alcohol for heating and lighting has not yet been allowed. In a note to our Ambassador (February, 1902) the Belgian officials say:—

"The point is under consideration and the Government are following attentively what is being done in foreign countries, notably in Germany and France. The question, however, has not the same interest in Belgium as in those countries. In France and Germany petrol pays a heavy import duty, while in Belgium it is free from any tax. From an economic point of view it seems probable that it will be always more advantageous to use petrol than alcohol even free of all duty for those purposes in Belgium."

Apparently the only products containing methylated spirits that can be sold are varnishes.

All the other denatured spirits are for use in the factories only, and the denaturing is done under the supervision of officers at the works. Accounts have to be kept at the works of the quantity of methylated spirits used daily. Excise officers frequently take stock of the methylated spirit, and may verify quantities of products made. No stills allowed on works, except when specially authorised under exceptional circumstances.

Two hectolitres at 50° (44 galls.) is the minimum quantity that can be denatured.

Quantity of spirits on which duty remitted in 1901, 21,292 hectolitres (468,424 galls.). Of this—

150,000 galls. were used in making common ether.	
121,000	vinegar.
105,000	varnishes.
58,000	artificial silk.
434,000	

Leaving 14,000 galls. for the other trades.

The conditions under which denatured spirit is allowed in Belgium are evidently less favourable than in this country, as, exclusive of the cost of the denaturing agents, a duty of about 5*l.* per proof gall., or 8*l.* at 60 over-proof is charged.

By a law passed in 1902, the Belgian Government is authorised to grant total or partial exemption from the import tax on alcohols intended to be used exclusively

for industrial purposes. The alcohol must first be denatured.

The following table shows the quantity of denatured alcohol used in the various kinds of industry in Belgium since the beginning of 1902.

Table showing for each class of Industry, the Quantity of Denatured Alcohol Used during the Years 1902 and the first Nine Months of 1904.

Class of Industry.	Quantity of Denatured Alcohol used.	
	1902.	1903.
	Galls. at 50°	Galls. at 50°
Vinegar	174,218	276,760
Varnish	117,104	123,244
Aniline colours	1,628	2,508
Hats	3,212	2,354
Fulminate of mercury	179	3,146
Collodion	1,122	3,058

PATENT SPECIFICATIONS may be obtained by post by remitting as follows:—

English.—8*sd.* each, to the Comptroller of the Patent Office, C. N. Dalton, Esq., Southampton Buildings, Chancery Lane, London W.

United States.—1*s.* each, to the Secretary of the Society.

French.—1 fr. 25 c. each, to Belin et Cie., 56, Rue des Francs-Bourgeois, Paris (3^e).

PLANT, APPARATUS, AND MACHINERY.

ENGLISH PATENTS.

Drying Apparatus; Vacuum — R. Haack, Godesburg, d. Sürther Maschinen-Fabrik, vorm. H. Hammerhmidt, Sürth, Germany. Eng. Pat. 7010, March 23, 1904.

See Fr. Pat. 341,672 of 1904; this J., 1904, 858.—T. F. B.

Drying Apparatus; Impts. in — W. J. Wells, Decatur, Ill. Eng. Pat. 23,183, Oct. 27, 1904.

A drum provided with double walls is mounted on hollow trunnions so that it can be rotated. Steam is introduced through one of the trunnions into the space between the walls of the drum and from thence into closed pipes, controlled by valves, projecting into and across the interior of the drum. Drip pipes are arranged to collect and carry off the condensed water. Steam can be sprayed directly into the drum, which is provided with a charging door, having a flanged cover, and with a flange for the escape of vapour passing through one of the trunnions. The apparatus is designed more particularly for drying material from which oil has been extracted. The material to be extracted, is placed in the drum, the solvent is added and the drum is rotated, until the solvent has taken up the matter to be extracted, the rotation of the drum is stopped, and the solution run off. The drum is then again rotated and steam admitted to the hollow walls of the drum and cross pipes, volatilizing the solvent adhering to the material, which passes off by the escape pipe. The last traces of solvent are removed from the material by means of hot steam.

—W. H. C.

Refugal Machines for Separating Liquids from Solids, such as Water from Ground Ore, and for Filtering the Separated Liquids; Impts. in — J. C. Fell, London. Eng. Pat. D. E. Bigelow, Kalgoorlie, W. Australia. Eng. Pat. 8298, April 11, 1904.

A vertical spindle A running in the footstep A¹, guided by the bearing A² attached to the standard bracket B,

and driven by the pulley E has a "feeding drum" C loosely fitted on, but prevented from revolving on it by the "feathers" A³. Webs C² preferably in the form of helices are attached to the casing C and support the outer casing C³ which carries a drum C⁴, having the screw surface D formed on its outer face. A spiral groove D¹, in the same direction as the screw D and having perforations D², is formed on the inner surface of the drum, to the top of which the flat ring D³ is attached. A second "hub" E¹ carrying the flange E² and the perforated drum E³, on which the filtering fabric is placed, and provided with the flanges E⁴ and E⁵, is fitted so as to revolve on the spindle A. This drum is driven at a different speed to the drum C by means of the pulley E⁶ which has a different diameter to that of the pulley E.

The outer casing G, carried on the framework F¹ is provided with an annular trough G¹ and outlet pipe G², with one or more intermediate troughs and outlets G³ and G⁴, with "hand-hole doors" H and with the flange N². An exterior annular trough K, with a hollow outer wall K¹ forming a steam jacket, supplied with steam by the pipe P² and having a drain pipe K³ and an outlet shoot N¹, is attached to the upper part of the casing G. A bevel spur wheel M driven by the pinion M¹, shaft M², and pulleys M³, runs in the V-shaped groove K², and carries the scrapers N.

Pulp is fed into the machine by the pipe P¹, passes down through the webs C², and is forced upwards by the screw D, the rate of rotation of which is different from that of the drum E³. The liquid passes away through the casing E³ to the trough G and the outlet G², any excess of pulp escaping through FF and the trough P. Washing water enters by the pipe D⁴, passes through the perforations D², washes the pulp and runs off through G³ and G⁴. The dried pulp passes over the flange E⁴ into the trough K, where it is further dried by the steam jacket K¹, and is then discharged by the scrapers N through the outlet N¹.

—W. H. C.

Filters; Impts. in — H. Breyer, Kogel, and A. R. Jurnitschek von Wehrstedt, Puchberg, Austria. Eng. Pat. 14,487, June 27, 1904.

See Fr. Pat. 344,351 of 1904; this J., 1904, 1080.—T. F. B.

UNITED STATES PATENTS

Centrifugal Separating Apparatus. E. G. N. Salenius
Stockholm. U.S. Pat. 784,231, March 7, 1905.

The claim is for a central feed inlet, having upright distributing chambers leading into the spaces between the inclined division plates of the basket or bowl of the centrifugal separator (see figure).—W. H. C.

Evaporating Apparatus: Vacuum ——. T. Suzuki,
Sunamura, Japan. U.S. Pat. 785,238, March 21, 1905.
SEE Eng. Pat. 19,186 of 1904; this J., 1904, 1202.—T. F. B.

Liquids: Apparatus for Raising ——. G. Hantke,
Warsaw, Russia. U.S. Pat. 785,307, March 21, 1905.
SEE Fr. Pat. 345,204 of 1904; this J., 1904, 1203.—T. F. B.

Drying Pasty Substances: Method of ——. M. Ekenberg,
Assignor to M. Ekenberg's Aktiebolag, Stockholm.
U.S. Pat. 785,600, March 21, 1905.

The substance to be dried is forced in an upward direction from the container A through the passage B, on to the surface of the heated cylinder C, which is rotated in the direction of the arrow within the vacuum chamber D. The substance is thus spread in a thin layer upon the surface of the cylinder C, and is carried round and dried by the combined influence of the heat and vacuum, being finally removed by the scraper E and collected in the receiver F. The substance itself serves to prevent the air from entering the vacuum chamber through the opening B.—W. H. C.

FRENCH PATENT.

Filter formed of Fibrous Materials arranged in Layers of Increasing Compactness. W. Stavenhagen. Fr. Pat. 347,740, Nov. 8, 1904.

The fibrous material B is placed on a flat surface A, and is pressed down, in the direction shown by the arrows, by the perforated plate C, which is furnished with projections D. Fig. 1 shows the arrangement at the first contact of the plate C with the material, and Fig. 2 the

operation completed. The increasing density of the compressed filtering medium is shown in Fig. 2 by the shading lines. The process may also be reversed, that is to say, the material may be placed on the perforated plate C and pressed down by the flat surface A. —W. H. C.

II.—FUEL, GAS, AND LIGHT.

Suction-Gas Plants. F. H. Bowman,
Electrician, 1905, 54, 1005—1007.

THE author summarises the advantages of suction-gas producers as follows:—They are reasonable in cost and yield a cheap and regular supply of gas; they are perfectly safe from explosion, occupy a small space (a brake-horse-power plant will stand in a space 6 ft. by 1 ft.), are simple in design and in operation, and need no unskilled labour. There is no escape of poisonous gas, as the gas production ceases when the engine stops. The producers are always ready for work, and require no gas holder. It is pointed out that while with an average steam plant there is a loss of 28 per cent. of the available heat energy of the fuel before the steam reaches the engine, with a producer plant this loss is only 13 per cent. Further, the gas is not liable to losses by condensation, as is the case with steam.

The composition of the gas from a gas producer of the Dynamic Gas Co., is given as: carbon monoxide, 58; hydrogen, 20.3; oxygen, 0.2; carbon dioxide, 7.8; nitrogen, 49.9 per cent.; the average thermal value is 150 B.Th.U.

The comparative cost of power is given below:—With a 12 h.p. gas plant 0.51d. per b.h.p. or 0.704d. per Board of Trade unit.

With a similar-sized steam plant 1.415d. per Board of Trade unit.

With a larger steam plant 270 kw., at 80 per cent. efficiency, 0.51d. per kilowatt hour.

With a 130 h.p. gas plant, at 80 per cent. efficiency, 0.45d. per kilowatt hour.

author states that the efficiency of a gas engine does all off in the same ratio as that of a steam engine decreasing load, and that for installations up to p. a suction producer using anthracite is best, or installations larger than 1000 h.p., a pressure engine using bituminous coal, with recovery of residuals to produce on full load a brake horse power for per hour.—W. H. C.

ENGLISH PATENTS.

Carbons and the like; Method of Enriching — Denaturing Alcohol. E. Phillips, Coventry. Eng. Pat. 7793, April 2, 1904.

or to lower the specific gravity of a liquid hydrocarbon rendering it more suitable for power purposes, the hydrocarbon is dissolved in it. Petroleum is stated to be improved in quality by passing a gas of acetylene or methane through it. The passage of gas may be continued after the liquid is saturated, whereby an enriched gas is also obtained. This is also applicable to the denaturing of alcohol.

—T. F. B.

Gas [Generating] Apparatus. F. Thuman, London. Eng. Pat. 6335, March 15, 1904.

Pat. 342,578 of 1904; this J., 1904, 930.—T. F. B.

Enriching Machines; Impts. in —. C. S. Kline, Erie, Col., U.S.A. Eng. Pat. 28,152, Dec. 22, 1904.

metal tank, with insulating coatings of tar inside, is divided into two unequal compartments by a partition. The smaller compartment is for the hydrocarbon in enriching the gas, and is fitted with a stirrer, &c., whilst the larger compartment, or mixer, is divided by a number of partitions, so as to compel the gas to take a zig-zag course. The intermediate space between these partitions is packed with strips of redwood sponge and vegetable fibre, preferably loofah. The gas does not reach to the bottom of the mixing chamber, but leave a certain free space for the liquid carbon, which is drawn up thence by the capillary action of the redwood bark and brought into contact with the gas.—C. S.

Incandescent Mantle. E. Crossley, Liverpool. Eng. Pat. 9622, April 27, 1904.

is made in the ordinary way are dipped into hydrochloric acid, "to purify the rare earths and destroy any impurities," and are then dried for 24 hours. The mantles are then dipped in a solution of platinum bichloride, to which a small quantity of dyestuff, as chrysoidine, has been added.—L. F. G.

Electrodes for Arc Lamps. W. R. Whitney, Boston, U.S.A. Eng. Pat. 26,917, Dec. 9, 1904. Under Internat. Conv., Dec. 10, 1903.

The electrodes are composed of pure metals, such as zirconium, molybdenum, tungsten, chromium, uranium, and vanadium, or of alloys containing more of these metals.—L. F. G.

Light Electrodes; Impts. in —. W. S. Weedon, Albany, N.J., U.S.A. Eng. Pat. 26,922, Dec. 9, 1904. Under Internat. Conv., Dec. 10, 1903.

The electrodes are made of an alloy containing about 10 per cent. of titanium and 65 per cent. of iron, formed into a plastic mass with glycerin or other binding material, rolled or pressed, dried, and fired at 1000°—1200° C. Blocks of ferro-titanium may be used.—C. S.

Working Rods; Impts. in [Inclined] —. C. J. G. Bradford. Eng. Pat. 8659, April 15, 1904.

A tapered hollow pyramid is mounted on the rails across the top of the hopper, by which the inclined rods are charged. Within this pyramid is mounted a smaller pyramid supported by the same rails, and having an approximately the same area as the opening of the outer hollow truncated pyramid. The coal is fed above the device by any suitable means, and as

it falls, slides down the space between the two pyramids, and is thrown into the hopper in an inclined direction, being thus evenly distributed.—W. H. C.

UNITED STATES PATENTS.

[Fuel] Bricks; Process of Manufacturing — from Refuse Coal or Coke. J. Haanersschlag, Straßburg, and H. S. Gerdes and O. Broste, Bremen, Germany. U.S. Pat. 786,028, March 28, 1905.

SEE FR. PAT. 344,225 OF 1904; THIS J., 1904, 1141.—T. F. B.

Gas; Apparatus for Manufacturing —. B. Loomis, Hartford, Conn., and H. Pettibone, New Rochelle, N.Y. Assignors to Power and Mining Machinery Company, New York. U.S. Pat. 781,576, March 14, 1905.

THE claims refer to a gas-generating and power plant consisting of three (or a pair) of cupola generators, the tops of which are connected by valved pipes, and also the bottoms, and a gas outlet pipe from one of the bottom connecting pipes, so that one of the generators can be cut out of the series for cleaning and repairing. The gas outlet pipe is connected with a scrubber and governor, and the gas engine, the exhaust pipe of which connects with branches to the bottoms of each of the generators, whereby the spent gases are utilised and the fires kept open and clean.—W. C. H.

Gas; Method of Making and Delivering —. B. Loomis, Hartford, Conn., and H. Pettibone, New Rochelle, N.Y. Assignors to Power and Mining Machinery Company, New York. U.S. Pat. 784,870, March 14, 1905.

THE combustible gas generated in a body of incandescent fuel is supplied to a gas engine, and the gaseous products of combustion in the engine are returned by the impulse of the engine to the body of fuel, whereby the ashes are removed from the interstices of the fuel and the mass is kept open. The products of combustion may be discharged into a second body of incandescent fuel, thereby converting the water-vapour and carbon dioxide into hydrogen and carbon monoxide by passing them through both bodies of fuel.—W. C. H.

Gas Producer. A. B. Duff, Pittsburg. U.S. Pat. 786,200, March 28, 1905.

SEE FR. PAT. 337,122 OF 1903; THIS J., 1904, 436.—T. F. B.

Gas-Washer. P. Meehan, Lowellville, Ohio. U.S. Pat. 784,748, March 14, 1905.

THE washer consists essentially of two vertical chambers connected at the bottom by a horizontal chamber. Gas enters the top of one vertical chamber and passes down over a series of conical and basin-shaped baffles, on to which water is sprayed—the gas being thus alternately expanded and contracted. Vertical scrubber plates are arranged in the horizontal vessel, and water is sprayed on to them. The gas then passes up through a number of spirally arranged baffle-plates in the second chamber, in the upper part of which is arranged a series of heated pipes for drying the gas before it reaches the outlet. These pipes are arranged between two heads extending across the chamber, and are heated by steam. The horizontal chamber is provided with an overflow opening, controlled by a gate, at one end, and through the other end a series of jets are applied to the surface of the water and are directed towards the overflow. A trough or hopper bottom is provided at the bottom of the collecting chamber, together with cleaning valves.—W. C. H.

FRENCH PATENTS.

Alcohols [and Hydrocarbons]; Solidified —. L. Denayronze. First Addition, dated Nov. 19, 1904, to Fr. Pat. 296,132, Jan. 13, 1900. (See Eng. Pat. 17,687 of 1900; this J., 1901, 976.)

ALCOHOLS and liquid hydrocarbons may be solidified by the addition of 5 to 15 per cent. of vegetable wax, stearin, or paraffin wax. The solid product may be used for lighting purposes, particularly for incandescent lighting,

by gently heating it in a receptacle connected with the burner; it is also suitable for heating purposes.—T. F. B.

Gas; System of Utilising Blast-Furnace Gas.—P. L. Hulin. Fr. Pat. 318,177, Jan. 30, 1904.

THE efficient use of blast-furnace gas in steel furnaces or gas engines is rendered difficult owing to the low thermal value of the gas and the large quantity of dust contained in it. It is proposed to overcome the difficulty by combining coke ovens with a blast-furnace. The waste gas from the latter is used to heat the coke ovens, thus producing coke for the blast-furnaces, and a gas of much higher calorific value which can be easily purified. This gas is then used either for gas engines, steel-melting furnaces, under steam boilers or in any other way. It is claimed that great economy is thus effected.—W. H. C.

Gas; Process of Manufacturing and Using a Portable Illuminating —, by means of Distilled Gas. H. Blan. Fr. Pat. 347,508, Oct. 28, 1904.

THE gas obtained by distillation is cooled by water, and compressed to such an extent that all the liquefiable gaseous components are liquefied, and the liquid thus obtained is transferred to vessels, capable of withstanding a considerable pressure, from which the liquid is drawn off by means of an arrangement for reducing the pressure.—W. C. H.

Gas for Motive Power and other Applications; System and Apparatus for the Production and Use of Inflammable —. W. H. and G. E. Russell. Fr. Pat. 347,554, Oct. 29, 1904.

THE apparatus consists of a vessel provided with an air-inlet and a gas-outlet, and containing, between these, a mass of absorbent material, which can be charged with a volatile combustible liquid. Through the wall of this main vessel is inserted a narrow deep vessel, containing a rod of zinc, surrounded by some absorbent material impregnated with a dilute acid, for the production of hydrogen, which escapes through openings into the main vessel. The air-inlet of the main vessel is connected with a perforated distributing pipe which supplies air to the absorbent material in the vessel. Within the main receptacle, a vessel is arranged to contain a suitable volatile liquid, and provided with an outlet, controlled by a cock, opening on the exterior for the supply of the liquid direct to the motor and also having another valved outlet, communicating with the interior of the main receptacle. The engine can thus be supplied with either the volatile liquid direct, or an explosive mixture of gas and air, and the valves provided allow the ratio of the gas and air, and also the quantity of the explosive mixture supplied to the engine to be controlled. The claims also include the use of turpentine as the volatile liquid.

—W. C. H.

Gas Jet to Burn under Water or other Liquid; Impts. in —. The Smethurst Furnace and Ore Treatment Syndicate, Ltd. Fr. Pat. 347,791, Nov. 11, 1904.

THE jet or burner is shown in Fig. 1, in vertical section and in Figs. 2 and 3, which are transverse sections on the lines X—X, and Y—Y respectively. The mixture of air and gas arrives by the pipes A, A, which have a diameter of 25 mm., increasing to 31 mm. at the points B, B, to 50 mm. at C to 75 mm. at D, and to 100 mm. at E. The tube D is filled with smaller tubes F, 12.5 mm. diameter and about 900 mm. long. The tube E is also filled with smaller tubes G, which have an internal diameter of 25 mm., the spaces between the tubes G being filled with pieces of tubing H of a smaller diameter and with wire gauze K, having 30 meshes in 25 mm. The lower ends of the tubes G are contracted in order to increase the velocity at this point, and are protected by wire gauze caps K'. These dimensions are important to prevent the gaseous mixture firing back. A cone M is adjusted around the orifices of the tubes G to further concentrate the flame, and to induce a current of liquid (in which the burner is immersed) through the pipes L, L, which have adjustable ends L', L', below the termination of the bell N, which is provided with lateral openings P. The burning jet induces a current of the liquid, through the pipes L, L, which is heated by the flame and passes out of the openings P. In this way, a continual

circulation is produced, which it is claimed prevents the shock caused by the return of the liquid against the burner, and also prevents the deposition of solid matter at the burner.—W. H. C.

Gas Producer —. G. Brandtstetter, R. Freund, and A. Ulrich. Fr. Pat. 347,908, Nov. 14, 1904.

FIG 2

producer is shown in vertical section in Fig. 1, and in section on the line A B in Fig. 2. The chief producer charged through the valve D, from the hopper F, where it undergoes a partial preliminary distillation by the action of the gas; B is an auxiliary producer communicating with F and A. Water is injected by the pump Q, through the valve R, into the vaporiser P, embedded in the brickwork and heated by transmission through the wall of the producer. The steam formed in the coil is injected into the main producer at H¹ and draws the gas and tar formed in the main producer through the auxiliary producer B, to the main grate C, the tar being gasified or burnt. The primary air enters through the pipes G and is heated before it reaches the space beneath the grate C. The gas produced passes through the outlet pipe M. The steam may be condensed by the exhaust gas from the engines. Two modifications of the apparatus are described and illustrated.—W. H. C.

Generator for Heavy Oils. A. A. Evens. Fr. Pat. 348,233, Nov. 24, 1904.

A mixture of heavy oil and oxygen is passed through a retort made of grey cast iron containing a large percentage of graphite. The interior of the retort is coated with a layer of agate, and the retort is heated by passing the hot gas from the motor through a jacket surrounding the retort. It is stated that in the presence of the plumbago the mixture is entirely split up by the heat into gas and free carbon. The latter is burnt into its oxides by the oxygen mixed with the oil.—W. H. C.

Luminescent Mantles; Process for the Manufacture of the same with Rare or Other Earths. J. Moeller, E. Schleier, and E. de Valeriola. Fr. Pat. 347,654, Nov. 4, 1904.

Threads used for making the mantles are impregnated with a solution of luminescent or other compounds, such as nitrates of the rare earths, and, after subsequent drying, are exposed for a relatively short time to the action of ammoniacal vapours, with the purpose of changing only the nitrates into hydrated oxides; they are then washed to remove the ammoniacal double nitrates and dried in the partial alteration of the luminescent salts, and finally woven. In place of threads, pieces of woven material or any artificial threads may be subjected to the same treatment in the manufacture of mantles. By this process it is said that the threads are impregnated with luminescent nitrates and covered with an impermeable layer of hydrated oxides, and that the presence of these compounds gives rise to a special chemical combination between the oxide molecules at the time of igniting the mantle.—W. C. H.

Incandescent Lamps; Filaments for —. A. Just and F. Hanaman. Fr. Pat. 347,661, Nov. 4, 1904.

The body to be raised to incandescence is composed of tungsten or molybdenum or an alloy of these metals, or of tungsten or molybdenum or a compound of these is impregnated with an organic agglutinant, and the carbon is introduced by placing the filaments in an atmosphere of carbon tetrachlorides of these metals in the presence of a constant current of free hydrogen, and heating the filaments to incandescence, to bring about a substitution of tungsten or molybdenum for carbon.—W. C. H.

Incandescent [Gas] Lighting; Material for —. J. H. Ladd. Fr. Pat. 348,133, Nov. 19, 1904. Under Internat. Conv., Nov. 24, 1903.

See Eng. Pat. 25,698 of 1903; this J., 1904, 1205.—T. F. B.

GERMAN PATENTS.

Gas-Producers with a Horizontal Gasification-Zone; Decomposition of Tar and Condensed Aqueous Liquor in —. J. Schlör. Ger. Pat. 155,742, August 25, 1902.

In the bottom of the horizontal gasification-zone of an annular gas-producer, in the part furthest removed from the fuel, is cut a groove or channel, forming a chamber in which tar and condensed aqueous liquor collect. The temperature of this chamber is somewhat lower than that of the gasification zone, so that the tar is not again converted into vapour until the temperature of the gasification-zone is such that the volatilised tar is decomposed into permanent gases.—A. S.

Water-Gas Generator and an Illuminating-Gas Plant in which the Illuminating Gas is Diluted with the Water-Gas; Method for the Utilisation of —. W. Buch. Ger. Pat. 156,677, April 7, 1903.

In the case of a partial or complete stoppage of the illuminating-gas plant, the water-gas is passed through a carburetting apparatus charged with suitable oils.—A. S.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, PETROLEUM, AND MINERAL WAXES.

Petroleum; Behaviour of Pennsylvanian — towards Polarised Light. M. Rakusin. Chem. Zeit., 1905, 29, 360.

A 10 PER CENT. solution of Pennsylvanian crude oil in benzene examined in a 50 mm. tube in the polarimeter, was found to be dextro-rotatory (0.1°). The relative behaviour of this oil and Baku crude oil, as regards action on polarised light, indicates that the former contains less than one-fourth as much "molecular carbon" as the latter. The optical activity indicates organic origin and an asymmetrical structure of the hydrocarbon molecule in Pennsylvanian oil. The laboratory distillates are also dextro-rotatory, this property being inherent to the hydrocarbon and not due to the complex refining process; and the same behaviour is also exhibited by a 3 per cent. solution in benzene of the residue left at 250° C., when examined in a 50 mm. tube, the concentration indicating the proportion of "molecular carbon" ("Kohlige Substanzen") to be three times greater than in the Pennsylvanian crude oil.

The presence of "molecular carbon," which has also been shown by Charitschkoff, disproves the theory of a non-vegetable origin of petroleum. Moreover, in conjunction with the optical activity of the oil, it points to the formation of petroleum as the result of extremely protracted carbonisation at moderate temperature (with elimination of hydrogen). From the relative proportions of "molecular carbon," Pennsylvanian oil seems to be of more recent origin, geologically speaking, than that of Baku. Since all petroleum obtained by the synthesis of inorganic substances lack these two properties, an organic origin of this natural oil is indicated.—C. S.

"Pipe Wax" in Boryslaw Crude Oil. M. Wielezynski. Chem.-Zeit., 1905, 29, 364.

BORYSLAW crude oil contains in suspension solid hydrocarbons, intermediate between petroleum and ozokerite, which obstruct the boreholes and pipe lines, and render frequent cleansing necessary, the pipe lines being rinsed out with warm water or warm Schodnica crude oil, which is low in paraffin-wax. The product recovered in this way is locally termed "kindybal." It has the sp. gr. 0.9397 at 15° C., solidifying point 60° C., and m. pt. 61°–62° C.

On distillation it furnishes fractions ranging in sp. gr. from 0.7775 to 0.8305, and containing in the aggregate 24.3 per cent. of paraffin-wax. All the fractions from the 3rd, with a sp. gr. of 0.8186, to the last (11th) of sp. gr. of 0.7838, were semi-solid at the ordinary temperature. The collective fractions Nos. 5 to 8, had a solidifying point of 36° C. The substance is employed for mixing with waxes of high melting point, or is distilled for paraffin scale.—C. S.

Ammonia: Extraction of —, from Gas Products by Dry Distillation. Soc. F. Brunck. First Addition, dated Nov. 5, 1904, to Fr. Pat. 231,077, of April 9, 1903. (Compare Eng. Pat. 8287, of April 9, 1903; this J., 1903, 795; and U.S. Pat. 773,784, of Nov. 1, 1904; this J., 1904, 1147.)

ACCORDING to the main patent, the ammonium sulphate formed in the vessel in which the ammoniacal gases come into contact with sulphuric acid, crystallises therein, and the crystals are withdrawn thence from time to time. Under the present Addition, the solution of ammonium sulphate (with the acid in excess) formed in the recipient vessel, is run continuously while hot into a series of coolers, from which, as crystallisation is effected, the cooled and acid liquid is pumped back into the closed cylinder receiving the gases, a supply of fresh acid being added as needed.—E. S.

Benzols and their Simple Hydroxy Derivatives: [Electrolytic] Process for the Production of —. L. Scholvién. Fr. Pat. 347,862, Nov. 12, 1904. XI. A., page 446.

IV.—COLOURING MATTERS AND DYE STUFFS.

Dibenzalacetone and Triphenylmethane. A. Baeyer. Ber. 1905, 38, 1156—1164.

By acting on *p*-trichlorotriphenylcarbinol with less than the theoretical amount of concentrated sulphuric acid, in solution in chloral, an acid sulphate, $C_{19}H_{12}Cl_3 \cdot SO_4H + H_2SO_4$, is obtained in the form of brown prisms or needles with a greenish-blue reflex. *p*-Tri-iodotriphenylcarbinol, when treated in the same manner, forms an analogous compound $C_{19}H_{12}I_3 \cdot SO_4H + H_2SO_4$, in crystals which are brown by transmitted light and show a strong green, metallic lustre. The chloral serves to bind the water which is formed. The author attributes the formation of these acid salts, which he calls "dimolsulphates" to the fact that the bases are too weak to decompose the "dimolsulphuric acid" $(H_2SO_4)_2$, of which he supposes concentrated sulphuric acid to consist. The above described sulphates are immediately decomposed by water, with formation of the carbinol, and by alcohol with formation of the colourless carbinol-ether. The tin chloride double salts $C_{19}H_{12}Cl_4 + SnCl_4$ and

$C_{19}H_{12}I_4Cl + SnCl_4$ were also prepared as red crystals blue and green metallic lustre respectively. *p*-Tri-methyldimolsulphate $(CH_3O \cdot C_6H_4)_3 \cdot C \cdot SO_3H + I$ orange-yellow needles, soluble in alcohol with a yellow colour, which disappears on addition of was prepared in a similar manner to the above halogen dimolsulphates. With less sulphuric acid in chloral solution, another salt $(C_{22}H_{21}O_3 \cdot SO_4H)_2 + H_2S$ formed in red needles. From *m*-trianisylcarbinol $t(C_{22}H_{21}O_3 \cdot SO_4H)_2 + H_2SO_4$, could alone be obtained in a salt, such as the salts of triphenylcarbinol and derivatives, and "idiochromes" which are essentially coloured in themselves, such as Fuchson, Aur Homolka's base. The activity of the hydroxyl of triphenylcarbinol is, as a result of his more recent explained by the author. This group is only an acid solution, the activity being due to the present carbonium valency. The peculiar property of additive compounds with hydrogen, bisulphite and substances is then developed, the carbonium is through a single bond, having the properties of a bond. Thus, in the reduction of triphenylcarbinol in acetic acid solution, we have the equation:—

Diphenyl: Quinonoid Derivatives of —. R. Willstätter and L. Kalb. Ber., 1905, 38, 1232—1241.

DIPHENOQUINONE, $O \cdot C_6H_4 \cdot C_6H_4 \cdot O$, was prepared by oxidising *p-p'*-dihydroxydiphenyl with lead peroxide and silver oxide. The best results were obtained by oxidising to the corresponding quinhydrone with peroxide in cold ethereal solution and complete reaction with the same agent in suspension in benzene. The yield is 50—55 per cent. The crystals crystallise either in hard red needles or in small needles of golden yellow colour. It is stable in the air, volatile, odourless, and decomposed by alkalis, at hot water. In oxidising power it closely resembles quinone. It is difficult to separate the two benzenes by oxidation, but by boiling with lead peroxide and sulphuric acid, benzoquinone is formed in large quantities. Solutions of diphenoquinone are deep yellow in colour much more intensely coloured than those of benzoquinone. This fact deserves attention, as solutions of coerulein, its tetra-*m*-methoxy derivative, are coloured deep blue. Diphenoquinhydrone, $C_{24}H_{18}O_4$, is obtained by dissolving solutions, in equimolecular proportions, of diphenoquinone and *p-p'*-dihydroxydiphenyl, or, in the form of a violet sodium salt, by oxidation of diphenol disodium carbonate solution with potassium ferric chloride. Its solution in strong sulphuric acid is deep blue, resembling that of coerulein. By oxidation of benzene in indifferent solvents with silver oxide or lead peroxide, preferably in solution in boiling chloroform with lead peroxide, a substance of the empirical formula $C_{12}H_8O_2$ was obtained, and may be $NH \cdot C_6H_4 \cdot C_6H_4 \cdot NH_2$, $NH_2 \cdot C_6H_4 \cdot C_6H_4 \cdot N \cdot N \cdot C_6H_4 \cdot C_6H_4 \cdot NH_2$. Its solution is yellow and more intense in colour than those of diphenoquinone. It is not reduced by sulphurous acid, readily reduced to benzidine with dilute acid and dust. With nitrous acid the base forms soluble yellow diazo-salts. These combine with naphthalene, forming a compound which is of a more yellow colour than Congo Red, but does not dye directly.—E. F.

Diazoamines of Diphenylamine, Derivatives of Homologues of Aniline and the Naphthylamines. L. Vignon and J. Simonet. Comptes rend., 1905, 140, 788—790.

AN extension of the study of the action of diazo aromatic amines on diphenylamine (see this J., 1904, 564 and 1023). By the addition of an aqueous solution of sodium nitrite to an alcoholic solution of the amine and diphenylamine, precipitating by cold water

ing the solution with ether, the diazoaminolamines, $R.N_2N(C_6H_5)_2$, derived from the three amines and from *o*-xylydine were isolated in a pure form. *m*-Xylydine gave a red oil possessing the properties of a diazoamino compound, but the pure compound could not be isolated. *p*-Xylydine gave no reaction, and *o*-xylydine produced diazoaminonaphthalene when by the above process, but by the action of diazo-naphthalene chloride on diphenylamine, coloured products were produced; they were unstable, giving off nitrogen during the corresponding naphthol, but they exhibited properties of diazoaminodiphenylamines. No such product could be obtained with the three aminophenols, *o*-antranilic or *o*-aminosalicylic acid.—T. F. B.

es; *Action of Formaldehyde and Sodium Bisulphite* — M. Prud'homme. Bull. Soc. Ind. Mul., Procès-verbaux, 1904, 184—185.

ases are produced by the joint action of sodium hydroxide and formaldehyde on diamines, such as benzotolidine, azoxyaniline, *m*-azoxytoluidine, &c. the amino groups being acted upon and converted to $NH_2CH_2SO_3H$ group. When diazotised and mixed with the usual dyestuff components, these dyestuff compounds which dye cotton from an alkaline bath and wool and silk from an acid bath.—E. F.

and Aniline-salt; *Action of Sulphur on* — O. Hinsberg. Ber., 1905, 38, 1130—1137.

aniline, aniline-salt and sulphur are melted together at $-180^\circ C$, at least four crystalline substances are obtained. These are: diphenylamine, in very small quantity only; dithioaniline, $NH_2.C_6H_4.S.S.C_6H_4.NH_2$, a yellow solid, to the amount of 10—15 per cent.; thioaniline, m. pt., $108^\circ C$; and a new thioaniline, m. pt., $58^\circ C$, which the author considers to be the *o*-*p*-diamino (4) $(NH_2).C_6H_4.S.C_6H_4(NH_2)(2)$. The author is of the opinion that the supposed thioaniline of m. pt., $85.5^\circ C$, described by K. A. Hoffmann, (Ber. 1894, 27, 2807) to be a mixture.—E. F.

Manufacture of Dyestuffs [Azo; *Manufacture of* —, *of Intermediate Products therefor*. J. Y. Johnson, son. From Badische Anilin u. Soda Fabrik, Ludwigshafen on Rhine, Germany. Eng. Pat. 1997, 29, 1904.

Publication of Feb. 26, 1904, to Fr. Pat. 338,819 of 1903; this J., 1904, 1026.—T. F. B.

Manufacture of Colouring Matter — J. Y. Johnson. From Badische Anilin u. Soda Fabrik. Eng. Pat. 19861, April 29, 1904. XIII. A., page 448.

2-Oxy- and 2-Diazo-1-oxy-naphthalene Mono-Di-Pri-sulphonic Acids; *Manufacture of* — T. R. To, London. From Aniline Colour Works, formerly Geigy, Basle. Eng. Pat. 10,235, May 4, 1904.

In the present no diazo compounds of the 1-amino-2-naphthalene sulphonic acids have been known, the sulphonic acids of 2-amino-1-hydroxy-naphthalene being diazotised in the usual manner, in the presence of mineral acids, the nitrous acid acts chiefly as an oxidizing agent. It is now found that, without the addition of mineral acids, and simply by mixture of these sulphonic acids with sodium salts with a solution of sodium nitrite, a diazotisation takes place which is increased by heating. This is, however, accompanied by oxidation. In the presence of additions of a neutral copper salt or of some metallic salts be made, the oxidation is entirely prevented, and the diazotisation is greatly accelerated. *Example*.—Preparation of 1-diazo-2-naphthol-4-sulphonic acid. A paste of 12 kilos. of 1-amino-2-naphthol-4-sulphonic acid in 50 litres of water is cooled with ice and mixed with a solution of 1 kilo. of copper sulphate, and then additions of 3.5 kilos. of sodium nitrite is slowly added, until diazotisation is complete, the solution is filtered and the diazo compound precipitated with hydrochloric acid. A. B. S.

UNITED STATES PATENTS.

Azo Compound [Azo Dyestuff], and *Process of Making Same*. E. A. Fournier, Assignor to H. A. Metz, Brooklyn, N.Y. U.S. Pat. Reissue 12,330, March 21, 1905.

Anthraquinone Dye [Indanthrene Dyestuff]; *Greenish-blue* — R. E. Schmidt, Assignor to Farbenfabriken of Elberfeld Co., New York. U.S. Pat. 785,124, March 21, 1905.

A new dyestuff is obtained by treating with formaldehyde and sulphuric acid the product obtained by heating 1,3-dibromo-2-aminoanthraquinone with cupric chloride, nitrobenzene and sodium acetate. The resulting new dyestuff dyes unmordanted cotton in greenish-blue shades from a suitable reducing vat containing alkali hydroxide and hydrosulphite.—E. F.

Anthraquinone Dye [Indanthrene Dyestuff]; *Green-blue* — R. E. Schmidt, Assignor to Farbenfabriken of Elberfeld Co., New York. U.S. Pat. 785,122, March 21, 1905.

The dyestuff described in U.S. Pat., 682,523 (See Fr. Pat. 309,503, 1901; this J., 1902, 42) (Indanthrene), is treated with formaldehyde and sulphuric acid. The product dyes unmordanted cotton in greenish-blue shades from a reducing vat containing alkali hydroxide and hydrosulphite.—E. F.

Anthraquinone Dye [Indanthrene Dyestuff]; *Green* — R. E. Schmidt, Assignor to Farbenfabriken of Elberfeld Co., New York. U.S. Pat. 785,123, March 21, 1905.

The product obtained by heating 1,4-diamino-2,3-dibromoanthraquinone with cupric chloride, nitrobenzene and sodium acetate is treated with formaldehyde and sulphuric acid. The new dyestuff obtained dyes unmordanted cotton in green shades from a reducing vat containing alkali hydroxide and hydrosulphite.—E. F.

Sulphur Dye [Sulphide Dyestuffs]; *Orange* — and *Process of Making same*. A. L. Taska, Assignor to K. Oehler, Anilin- und Anilinfarben-Fabrik, Offenbach-on-Maine, Germany. U.S. Pat. 785,675, March 21, 1905.

AZO-DYESTUFFS resulting from the combination of the diazo-compounds from easily volatile aromatic amines and monoacetyltoluenediamine ($CH_3 : NH_2 : NH : COCH_3 = 1 : 2 : 4$) are heated with sulphur at an elevated temperature in presence of benzidine or another base of the diphenyl series, and the product subsequently treated with alkali hydroxide. The dyestuffs formed in this way are soluble in alkali sulphide solutions, and dye cotton in orange-yellow shades from a bath containing sodium sulphide.—E. F.

FRENCH PATENTS.

o-Nitro-o-aminoacetyl-p-aminophenol and Azo Dyestuffs susceptible to Chroming Derived therefrom; *Process for Preparing* — A. Cassella and Co. First Addition, dated Jan. 27, 1904, to Fr. Pat. 339,442, Nov. 2, 1903.

SEE Eng. Pat. 3096 of 1904; this J., 1905, 83.—T. F. B.

Dyestuffs, Naphthalene [From Naphthalene]; *Production of Blue-black* — Badische Anilin und Soda Fabrik. Fr. Pat. 348,478, Jan. 30, 1904. Under Internat. Conv., Jan. 8, 1904.

SEE Eng. Pat. 2468 of 1904; this J., 1905, 23.—T. F. B.

Dyestuff, Mononitro, for the Manufacture of Lakes; *Production of a Red* — Badische Anilin und Soda Fabrik. Fr. Pat. 348,248, Feb. 4, 1904. Under Internat. Conv., Jan. 8, 1904.

SEE U.S. Pat. 750,716 of 1904; this J., 1904, 604.—T. F. B.

Dyestuffs of the Anthracene Series [Indanthrene Dyestuffs]; *Production of Grey* — Badische Anilin- u. Soda-

Fabrik. First Addition, dated Nov. 15, 1904, to Fr. Pat. 341,126, Jan. 26, 1904.

According to the original patent (this J. 1904, 820), certain diamino-anthraquinones are fused with potassium hydroxide to 180–200° C. According to this addition the same process is applied to the formaldehyde compounds of 1,5- and 1,8-diaminoanthraquinones. For instance, 300 kilo. of 1,5-diaminoanthraquinone-formaldehyde are incorporated, little by little, with 300 kilos. of fused potassium hydroxide, the temperature not exceeding 170° C. and kept at this temperature for one hour. The products dye vegetable fibres from an alkaline reducing vat in brownish-red shades, resembling Indanthrene in fastness and in general properties.—E. F.

Naphthylamine Sulphonic Acids, Applied 1,6- or 1,7- Manufacture of —. Actienges. für Anilin-Fabrikation. Fr. Pat. 348,149, Nov. 21, 1904.

1,4,6- or 1,4,7-NAPHTHYLAMINEDISULFONIC acid, or a mixture of these two acids as obtained by sulphonating naphthionic acid, is heated with an aromatic amine, with or without the addition of the hydrochloride of such amine, and with or without addition of benzoic acid. The sulphonic acid group is eliminated and the amino group arylated by this means. For instance, 17 parts of 1,4,6-naphthylaminedisulphonic acid, 15 parts of aniline hydrochloride and 50 parts of aniline are heated to boiling for six to eight hours, the whole made alkaline with sodium carbonate, the excess of aniline driven off with steam, and the sodium salt of phenyl-1,6-naphthylaminesulphonic acid precipitated by common salt.—E. F.

GERMAN PATENTS.

m-Nitrochlorobenzylsulphonic Acid; Process for Preparing —. Farbwerke vorm. Meister, Lucius und Brünning. Ger. Pat. 154,493, Aug. 24, 1902.

*m-NITRO-*o*-CHLOROBENZYL SULPHONIC* acid, (CH₂.SO₃H; Cl:NO₂ 1:2:5) is produced by nitrating *o*-chlorobenzylsulphonic acid with 1 mol. of nitric acid in presence of sulphuric acid. The *o*-chlorobenzylsulphonic acid is produced by the action of sodium sulphite on *o*-chlorobenzylchloride. Nitrochlorobenzoic acid results on oxidising the acid; nitrohydroxybenzylsulphonic acid is produced by the action of alkali hydroxide; ammonia gives nitroaminobenzylsulphonic acid, and aromatic amines produce the corresponding diphenylamine derivatives.—T. F. B.

[Dyestuffs] Oxazine Derivatives of the Anthracene Series; Process for Preparing —. Farbwerke vorm. Meister, Lucius und Brünning. Ger. Pat. 156,477, Oct. 24, 1903.

ATIZARIN in which the hydrogen in the 4 position is substituted by a hydroxyl or an amino group, is condensed with *o*-aminophenols in presence of boric acid. The sulphonic acids of the resulting oxazine derivatives are of use as dyestuffs. Thus, the sulphonated condensation product of Purpurin and *o*-aminophenol or *o*-aminoresol dyes wool in violet shades, and chrome-mordanted wool green shades; that from 4-aminosalizarin and *o*-aminophenol, when sulphonated, gives blue shades on wool in either case, whilst that from Purpurin-sulphonic acid and *o*-aminophenol dyes wool blue, and chrome wool, green. —T. F. B.

Dyestuffs, Sulphide, for Cotton; Process for Preparing Yellow —. Farbwerke vorm. Meister, Lucius und Brünning. Ger. Pat. 156,377, Dec. 15, 1903.

DYE STUFFS, which produce yellow shades on cotton from sodium sulphide solutions, are obtained by heating 2,2'-diamino-4,4'-oxaltoluide with three times its weight of sulphur, to 170°–200° C. for six to eight hours. The diamino-oxaltoluide is produced by heating together oxalic acid and *m*-tolylenediamine at 100–225° C. —T. F. B.

Dyestuffs, Monoazo, specially suitable for the Preparation of Lakes; Process for Manufacturing Yellow to Orange-Yellow —. Badische Anilin und Soda Fabrik. Ger. Pat. 156,352, Sept. 10, 1903.

YELLO to orange-yellow dyestuff, very suitable for the

preparation of colour lakes (said to be fast to acids, alkalis, and alcohol) are obtained by combining the diazo derivatives of benzene- or naphthalene-sulphonic acid with nitro-*m*-phenylenediamine or with nitro-*m*-tolylendiamine.—T. F. B.

Dyestuffs, Monoazo, specially suitable for the Preparation of Lakes; Process for Manufacturing Red —. Badische Anilin und Soda Fabrik. Ger. Pat. 156,353, Oct. 2, 1903.

THE phenyl ether of *o*-aminophenol-*p*-sulphon produced by reducing the condensation product of chlorobenzene-*p*-sulphonic acid and sodium phenylhydrazine is diazotised and combined with β -naphthol, prepared from this dyestuff in the usual manner, to give a fine red colour, and are stated to be insoluble in water, to alkalis and light, and to possess good covering power.—T. F. B.

Dyestuffs, Monoazo, susceptible to Chroming; Process for Preparing Black —. Badische Anilin und Soda Fabrik. Ger. Pat. 156,157, Feb. 5, 1904.

DIAZOTISED picramic acid is combined with an sulpho derivative of 1,8-aminonaphthol-5-sulphonic acid. The latter compound is obtained by the action of sodium sulphide on 1,8-aminonaphthol-5-sulphonic acid; the sulphamino-compound need not be isolated. The resulting dyestuff dyes wool from acid baths in violet shades, modified to very fast blue-black on subsequent chroming.—T. F. B.

Dyestuffs, Sulphide; Process for Preparing a Blue —. Kalle und Co., Ger. Pat. 156,478, Nov. 27, 1903.

A MIXTURE of *p*-phenylenediamine and *o*-hydroxyaniline is oxidised to an indophenol by means of potassium ferricyanide. The leuco-indophenol, obtained by carbon dioxide through the sodium sulphide solution, is heated with sulphur and sodium for about 20 hours at a temperature of 120°–150° C. The dyestuff, extracted from the melt in the usual manner, dyes blue shades on cotton from sodium sulphide baths. It is stated to have a greater affinity for cotton than the indophenol derived from phenyl-*p*-phenylenediamine.—T. F. B.

V.—PREPARING, BLEACHING, DYING, PRINTING, AND FINISHING TEXTILES, YARNS, AND FIBRES.

Silk; Its Treatment Before and After Dyeing —. G. H. Hurst. J. Soc. Dyers and Colourists, 1904, 99–102.

THE “boiling off” of silk is usually done in vertical constructed appliances; the author suggests that the Obermaier machine might be adopted for use in this process, especially when waste and Schappe silk are under treatment.

During the “boiling off” process, the silk loses a considerable weight (25 to 30 per cent.). This loss can be restored without impairing the lustre, by staining the silk in a solution containing 20 grms. of gelatin for one hour at 38°–49° C., squeezing, gently drying afterwards transferring to a solution containing 2 gms. of formaldehyde per litre. The gelatin is rendered insoluble and the silk somewhat stiffened by the treatment, the process does not interfere with the subsequent operations.—M. C. L.

Formic Acid; Application of —, in Wool Dyeing —. Mettner. Z. Farben- u. Textil-Chem., 1905, 4, 1.

FORMIC acid behaves like lactic acid in causing chromium of the alkali bichromate mordanting to become completely absorbed by the wool fibre in a bath in which it is applied, thus enabling the dyeing to be proceeded with in the same bath as that in which the mordanting has been previously accomplished. The

ff applied in this manner becomes perfectly fixed, the dyings produced being, in respect to fastness to washing, superior to those obtained by the usual method of dyeing and dyeing in separate baths. This method has been introduced into practice with satisfactory results, the wool being mordanted with 1.5 per cent. of light of potassium bichromate, and 2 per cent. of acid (80 per cent.), and the bath being heated to 110° C., and maintained at this temperature for 1½-2 hours.

The bath having then been cooled to some extent addition to it of cold water, the dyestuff, according to nature, mixed with cold or dissolved in hot water, is usually introduced into it. About 2 per cent. of acid is next added, and the bath is heated until it is boiled for about two hours.—E. B.

Discharges on Tissues Dyed with Red, Claret, Brown Azo Dyestuffs; Producing— with Sodium Hydrosulphite-Formaldehyde. "Société E. Zundel," Soc. Ind. Mulhouse, Procès-verbaux, 1904, 1—187.

For complete solution of the dyestuffs in the discharges used, an addition of phenol is made to the mixture. Only those dyestuffs which yield leucos not decomposed by energetic reduction, are used. Certain sparingly soluble oxazine dyestuffs, dissolved in phenol, become sufficiently fixed, without the addition of tannic acid or other mordant. The discharges are produced by steaming the printed tissues for four hours.

A white discharge is obtained upon the brown dye from Chrysoidine and diazotised *p*-nitraniline (see J., 1904, 657) by adding sodium carbonate to the discharge printing mixture.

Azo claret, more easily discharged than the *p*-naphthylamine Claret, is produced from β -naphthol and diazotised aminoazotoluene. Fatty substances must be added to the discharge mixture for a white discharge on this dye.

Alkaline acids and acid salts have a favourable influence on the action of the hydrosulphite compound. In instances, e.g., in the case of acetic acid, these may be applied in admixture with the steam. Another method for attaining the same end, is to prepare the steam-baths in acid salts or salts which have an acid reaction, sodium bisulphate (applied in a 1 per cent solution) or ammonium chloride.

For reserve-discharges upon H. Schmid's bronze dye (see J., 1904, 658) are obtained by adding sodium acetate to the ordinary hydrosulphite colour discharge mixture.

Insoluble azo dyestuffs are produced on the fibre by combining Chrysoidine with diazotised aminodiphenyl-, *o*-nitrotoluidine, benzidine, dianisidine, and *p*-naphthylamine respectively.

Claret which is readily dischargeable is formed from α -naphthylamine (and β -naphthol?).

Sodium hydrosulphite in the presence of an excess of soda acquires great stability and increased discharging power for most dyestuffs. Such a mixture gives

perfect discharges with most azo dyestuffs, but an exception is found in the case of Paranitraniline Red. It may be applied to effect a white discharge upon the complete bronze dye produced by dyeing first in red with β -naphthol and diazotised β -naphthylamine and then over-dyeing with a blue or grey substantive cotton dyestuff, a red discharge being simultaneously obtained by printing sodium hydrosulphite-formaldehyde along with the white discharge-mixture. A blue discharge is obtained by adding Indanthrene to the alkaline mixture.—E. B.

Hydrosulphites; Preparation of Alkali— by the action of Formates on Bisulphite compounds of Aldehydes or Ketones. A. Dubosc. Rev. Gen. Mat. Col., 1905, 9, 99—100.

STABLE hydrosulphites can be produced by heating to 104° C. an aqueous mixture of acetone sodium bisulphite and ammonium formate. If the mixture be kept alkaline, ammonium sesquicarbonate is produced, which distils off, leaving the hydrosulphite compound, which can be concentrated *in vacuo*. The reduction is really performed by the carbon monoxide from the formic acid. In practice, the mixture of "sulphite acetone or aldehyde" and ammonium formate, is heated to 84° C. At first hydrosulphite is formed, but later the carbon dioxide acts on the sulphite and forms carbonate. This can be avoided by working *in vacuo* and pumping off the carbon dioxide formed, or by adding a base the heat of formation of whose carbonate is less than that of sodium sulphite. Compounds of manganese, lead, zinc or ammonia may be used, especially the last, as it sublimes at 60° C., and the reaction takes place at 84° C.—A. B. S.

ENGLISH PATENTS.

Wool Washing and Scouring Machinery, applicable for Carbonising Wool and other Fibrous Material and for continuously Dyeing and Bleaching Wool, Cotton, and other Fibrous Material. J. Dawson, Rochdale. Eng. Pat. 7790, April 2, 1904.

The object of this invention is to provide improved mechanism for washing and scouring wool in the loose state, and especially for immersing the wool and for passing it in a continuous manner from one end of the tank in which it is being treated to the other end. Two series of rake frames A and B (see figures) are employed, each approximately of the same length as the tank A', and each composed of four or more longitudinal bars or tubes carrying prongs or forks D. Each bar or tube is provided, at the entrance end of the machine, with an immerser projecting downwards from it, and consisting of a narrow perforated chamber F of about the same width as the bar or tube. The bars or tubes have pivoted to them at each end and at one or more intermediate points, arms I attached at their tops to a transverse bar I' with which is connected a central rod J. The rods J may be coupled to one or more crank arms J', or they may be connected with the arms of a beam lever, with the object of causing the rake frames alternately to rise and to fall, and to be pushed forward, when the prongs are immersed in the liquor contained in

FIG 2

the tank, and to be carried backward towards the entrance end of the machine, when the prongs are out of the tank, prior to their entering the tank again.—E. B.

Wool and the like: Machinery for Washing, Scouring, Extracting, Neutralising, and Dyeing — J. Pease, J. V. Parker and J. Hustler, Bradford. Eng. Pat. 9323, April 23, 1904.

A TANK fitted with a false bottom in the form of a grid, has mounted on opposite sides of it, pedestals serving as bearings for cross-shafts driven from a shaft placed alongside the tank. The cross-shafts carry drums to which are, preferably, attached arms extending along them and projecting out from them nearly far enough to touch the grid. When employed in extracting vegetable matters from loose wool, the tank is constructed of wood or metal, and is lined with an acid-resisting material, and the drums and arms are composed of glass or porcelain, or of wood sheathed with lead, &c. The delivery rollers at the exit end of the machine are also, in such case, made of or

covered with acid-proof materials, and so constructed that their bearings and the adjacent parts shall be protected from the acid solution used. The tank is, further, so constructed as to facilitate its being cleaned out when required by means of jets of steam which are blown along its bottom, thus obviating the necessity of raising the false bottom.—E.

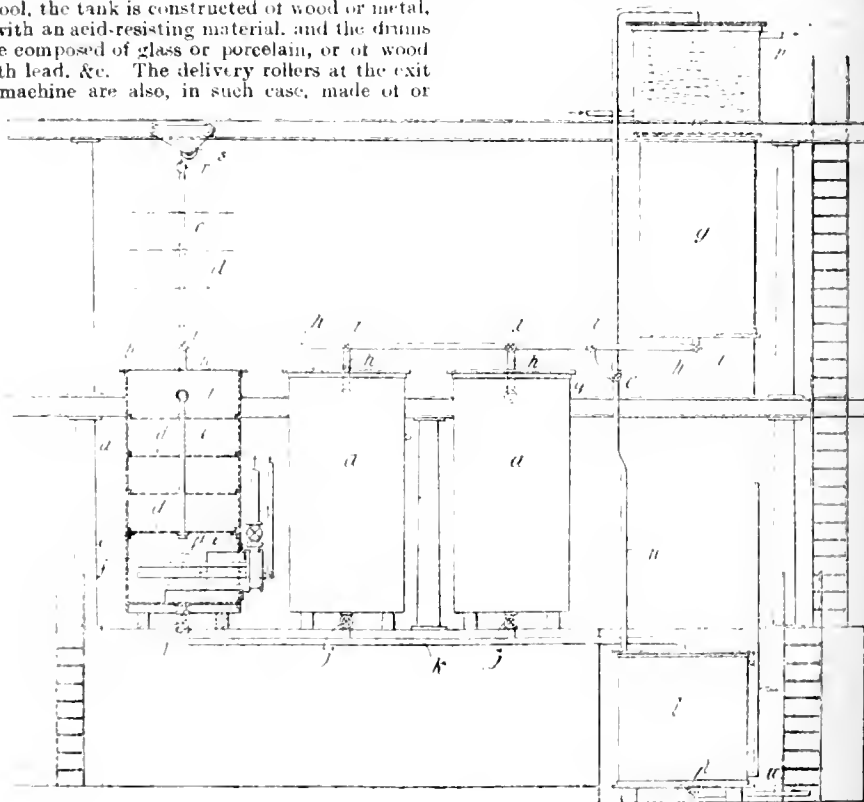

Wool Scouring; Machinery for — W. McNair, Rochdale, Lancs. Eng. Pat. 10,005, May 2, 1904.

In the usual squeezing arrangement, consisting of rollers, the upper one of which is movable vertically, is pressed down by weights which work through compound levers, it is found that the jerking up and down of weights is apt to cause damage to the machine. To avoid this the weights are now seated on springs which prevent sudden shocks.

To immerse the wool in the scouring tank the immerger is fixed on to a rod, one end of which is pivoted to the crank and the other end on to a rocking lever. A mechanism which drives the rakes also drives the immerger and gives it an elliptical motion. The motion can be suitably altered or modified. By another arrangement the immerger is moved horizontally by means of a lever connected to the first rake, and vertically by means of a cam.

In order to propel and agitate the wool in the washing trough, a number of immersers are fixed on to a shaft, one end of which moves with one of the rakes, while the other end passes between two rollers fixed on a rack at the opposite end. The immersers consist of rectangular boxes with perforated tops, and are fitted with flap valves which cover the perforations when the immerger is raised and so lift the enclosed water a short distance above the level of the liquid in the trough; this water in flowing back agitates the washing liquor. To deliver the wool from the machine to the squeezing rollers an arrangement of rollers is fitted, which is moved by means of levers and an elliptical gear-wheel so as to follow the inclined bottom of the trough. In another arrangement some of the rollers are pivoted on to a frame which has a horizontal motion of its own.—A. B. S.

Oil and Grease from Sponge Cloths, Cotton Waste, and all kinds of Grease-Laden Textile Materials; M

Means for Removing [Degreasing] — S. G. London. Eng. Pat. 10,156, May 3, 1904.

and oil-laden textile materials, such as cotton sponge cloths, &c., are deposited in a crate, formed of perforated plates *d* (see figure) attached to a central shaft *e*, and are thus brought into an extraction vessel *a*, the bottom plate *d* resting upon brackets *c* and leaving at the bottom of the vessel a space *f* in which a closed coil *f'* is placed. To effect the extraction of the matters, &c., the vessel is closed by a hinged cover *g*, a charge of "benzine" or other solvent is admitted from a container *g*. The solvent passes down through the crate, and, while doing so, it is heated by the coil and vaporised, being thus caused to act more fully. After the lapse of some time, the valve *i* at the top of the vessel is closed, and, a valve *j* at the bottom opened, the solution obtained is withdrawn to a still *h*, the solvent is distilled back into the container *g*. The extracted materials are dried in the vessel *a* by means of a steam coil and are removed from the vessel by means of a travelling hoist *s*. The extraction is rendered a continuous process by arranging a series of extraction vessels together and operating upon each of them in turn.—E. B.

eg, Bleaching, Dyeing, or Similarly Treating Hanks of Yarn, Slubbing, Warps and the like; Machine for — J. Ellis, Huddersfield. Eng. Pat. 9787, April 20, 1904.

is engaging in the teeth of a horizontal, fixed, rack, are loosely mounted upon the turned ends of a hub fixed at or near the top of a central, upright shaft. Sleeves to which reels are attached are secured to the pinions, the motion of the reels causing the reels to move simultaneously round their own axes and round the shaft. A circular trough in which water or dye-liquor is supplied is placed below the reels. When the apparatus is employed in washing, the hanks enter the trough on one side of a partition and flowing round the trough is withdrawn on the other side, the hanks of yarn, which are placed upon the reels as these are brought to the partition, being conveyed round the trough in the opposite direction to that in which the water is flowing and being removed from the trough after one passage round the apparatus. When used for dyeing, the trough is charged with dye-liquor and the hanks are conveyed round it as many times as is necessary to produce the shade required.—E. B.

Textile Fibres; Apparatus for — H. Rüssler, Weiler, Germany. Eng. Pat. 29,618, Dec. 31, 1904.

is wider at the bottom than at the top, conically shaped in the middle, and with holes at the bottom, is in a vertical position above the end of a steam pipe entering an outer chamber which communicates at its top with a dye-vat. The materials to be dyed enter into the latter between two sieves. When the material is turned on, the dye-liquor is set in motion and it rises in the outer chamber, flows over the sieve, passes downwards through the materials, and from the bottom of the vat again to the outer chamber. A steam coil, fixed between the lower sieve and the bottom of the vat, may be employed to hasten the dyeing of the dye-liquor.—E. B.

Textile Fabrics; Method and Apparatus for — J. Haddan, London. From "Crosset and Debattis," Liéumont-Verviers, Belgium. Eng. Pat. 29,094, Dec. 3, 1904.

issues, wound in the wet state upon a roller *F* (see Fig. 1), are unwound from this, and, after passing at full width over a suction apparatus *D*, with which they are kept in contact by means of a tension roller *K* (Fig. 1) and a guide roller *G*, are wound upon a roller *I*. The apparatus (also Fig. 2) has a head, consisting of "an oblong plate or pipe" *K*¹ (Fig. 2), produced by fixing at a certain distance apart two plates of brass or copper, the space between which corresponds with the width of the tissues to be dried, the width of the orifice *L* and the height of the head being so adjusted as to ensure a sufficient

extractive action without excessive friction upon the tissues. Below the orifice *L* are an enlarged opening *M* and a channel *N* leading into a chamber *P*, with which a pipe *C* connected with a suction cylinder *B* (Fig. 1) and suction pump communicates.—E. B.

Textile Fabrics, Paper, or other Lamellar Materials; Engraved Boulders or Rollers for Producing an Improved Reflecting Finish on — W. J. Pope and J. Hübner, Manchester. Eng. Pat. 7745, April 2, 1904.

A REFLECTING finish of a homogeneous or uniform character is produced upon fabrics by means of a roller upon the surface of which is engraved a design made up of circles or closed angular figures, the circles being so minute, and both the circles and the lines composing the angular figures lying so close together, as to be undistinguishable by the unaided eye. (See also Eng. Pat. 4907 of 1904; this J., 1903, 273.)—E. B.

UNITED STATES PATENTS.

Retting Fibrous Stock; Process of — J. E. Lappen, Decorah, Iowa, Assignor to L. L. C. Brooks and F. M. Catlin, St. Paul, Minn., U.S.A. U.S. Pat. 785,618, March 21, 1905.

FIBROUS materials, such as flax, are retted by a process which consists in boiling them under direct steam pressure first with lime and then with caustic soda.—E. B.

Dyeing Apparatus. D. F. Waters, Philadelphia, Pa., U.S.A. U.S. Pat. 785,283, March 21, 1905.

A DYE-VAT is combined with 1. a frame, upon which yarn-sticks, furnished with ratchet wheels are mounted, so as to be intermittently rotatable by means of an eccentric actuating a lever, and through this, a bar carrying pawls which engage with the ratchet wheels; 2. a liquor circulating wheel, mounted on a horizontal axis and arranged to revolve in connection with the motion of the eccentric, etc.; 3. a heating pipe at the bottom of the vat; and 4. a false bottom, between the pipe and the frame, terminating short of the opposite ends of the vat.—E. B.

Warp-Dyeing Machine. T. E. Davis, Winston-Salem, N.C., U.S.A. U.S. Pat. 785,597, March 21, 1905.

A COMBINATION of apparatus for dyeing yarns in the form of warps, comprising a dye-vessel with a perforated false bottom, below which a heating-medium feed-pipe is placed; a pair of reel-carrying shafts; slotted frames into which the ends of the reel-carrying shafts are fitted; spacing bars interposed between the reels; mechanism for moving the reels vertically up and down; rollers for drawing and squeezing the warps, revolving in unison with the reels; guiding and spacing pins mounted on opposite side of the frames; a warp-feeding guide carried by the frames, working in conjunction with one of the reels; a warp-guiding device and an adjustable warp-feeding guide.—E. B.

Metallizing Fabrics [by Electrolysis]; Process of —. C. Danilevsky and S. Tourchaninoff, St. Petersburg, U.S. Pat. 785,541, March 21, 1905.

"METAL" is first electrolytically deposited upon the fabric, which is then washed and treated with a mixture of stannous chloride and potassium cyanide.—E. B.

FRENCH PATENTS.

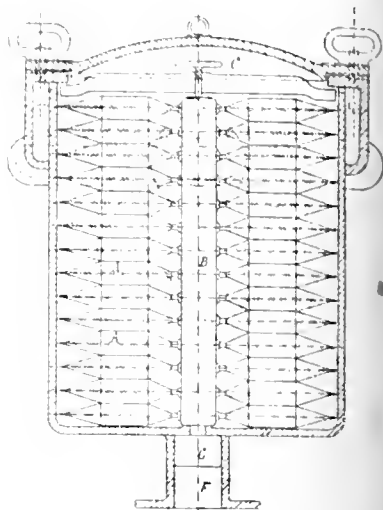

Cellulose Threads; Process for Making Brilliant —. R. Linkmeyer. Fr. Pat. 347,960, Nov. 16, 1904.

It is found that solutions of cellulose in ammoniacal copper solutions ("cellulose cupranmonium") are coagulated by solutions of alkali hydroxides as well as by acids. This process is utilised to produce artificial silk threads. The formed threads are washed either in water or in dilute acid. Such threads are stated to be perfectly transparent, and to possess great brilliancy; they are also said to be much stronger than cellulose threads produced by other processes, particularly when wet. The alkali appears to exert a similar increasing effect on the cellulose to that produced on cotton.—T. F. B.

Aniline Black on Wood; Process for Obtaining —. M. Prud'homme. First Addition, dated Jan. 26, 1904, to Fr. Pat. 333,386, June 25, 1903.

THE mordanting of the fibre with chromic chromate preparatory to dyeing it with Aniline Black, as described in the principal patent (see this J., 1903, 1315), may be accomplished by either of the following methods:— treatment in an aqueous solution of chromic acid, which is partially reduced; treatment with potassium bichromate (2 mols.) and sodium thiosulphate (1 mol.); treatment with chromic acid and sodium nitrite; treatment (hot) with potassium chromate (1 mol.) and a basic chromic salt (1 mol.). Instead of using excess of hydrochloric acid in the dyeing process, nitric or sulphuric acids may be used, and a part of the mineral acid may be advantageously replaced by an organic acid (particularly formic or oxalic acid). The dyeing may be carried out by immersing the mordanted fibre in the acid solution of aniline for a short time, and then removing it, and allowing the oxidation to finish in the air. Aniline may be replaced by other aromatic amines, e.g., the toluidines, xylydines, naphthylamines, phenylenediamines, benzidine, or amino-diphenylamines; for example, *o*-toluidine gives blue-black shades, and benzidine brown shades.—T. F. B.

Dyeing Threads on Bobbins; Arrangement of the Bobbin Apparatus for — by the Circulation of Liquor. C. Crépelle-Fontaine. Fr. Pat. 348,100, Nov. 12, 1904.

THE bobbins are held on perforated spindles A, which are fixed on a number of vertical tubes B, situated close together in a rectangular dye-vat, as shown in cross section in the accompanying figure. The bobbins are placed closely together as possible, in order to economise space and liquid. For further economy, the spaces between the bobbins at both ends may be filled by conical projections fixed on the sides of the vat and on the tubes B. The dye liquor is introduced through the pipe F, and upwards through each of the tubes B, and thence through the spindles A, penetrating the material on the bobbins, and overflows through orifices near the top of the vat into a channel which surrounds the vat, whence it is pumped off, and again introduced into the apparatus through E.—T. F. B.

Printing on Fabrics [with Nitrocellulose]; Process of —. A. Samuel. Fr. Pat. 348,015, Nov. 19, 1904.

A VARIETY of effects is said to be obtained by printing with nitrocellulose on dampened fabrics. The process may be conveniently carried out in a multi-colour printing machine, the apparatus used for printing in the first instance being employed for dampening the fabric. The nitrocellulose is applied in solution (e.g., collodion), by means of plain or engraved printing cylinders. It is pointed out that the preliminary dampening is essential for the production of brilliant effects.—T. F. B.

Threads of all kinds; Treatment of — [with Nitrocellulose]. A. Samuel. Fr. Pat. 348,137, Nov. 22, 1904.

TEXTILE threads closely resembling silk thread are produced by dampening any kind of thread, and then coating it with nitrocellulose. (Compare preceding abstract.)—T. F. B.

VI.—COLOURING WOOD, PAPER, LEATHER, &c.

er Dyeing; Practical Difficulties in — H. C. Beckett. J. Soc. Dyers and Colourists, 1905, 24, 3—111.

FORMITY of shade in leather dyeing is difficult to n, because no two skins are alike in fineness of grain, re, or shape; the skins are also often badly damaged, imperfections, e.g., "salt," tan-, and drench-stains be hidden by dyeing the goods dark green or chocolate s; goods possessing "tainted" grain are best dyed colours.

en dyeing a pack of skins, slight differences in the texture tend to cause a variation in the colour, must be allowed for when the goods are being dyed "with dye solution in the finishing processes.

the preparation of skins for dyeing, the goods are ly immersed in a weak solution of sulphuric acid; great amount of acid will tend to cause serious ge to the leather.

e tray or vat method of dyeing is customarily dyed when small quantities of leather are to be dyed; a large number of skins are being worked, the drum dle method is used. When chrome leather is being dyed, the greenish-blue colour, possessed by the skins ous to dyeing, materially affects the colour of the dyed er. Blacks are dyed by first drumming the skins ogwood extract solution, afterwards "fat liquoring" an oil emulsion, and finally passing them through an i striker" made of ferrous sulphate and a concen- d solution of tannin. Blacks obtained with coal-tar uffs are usually fairly satisfactory, but the leather the slight swollen effect produced by logwood, pier, sumach and fustic extracts are employed as mor- prior to applying the coal-tar dyestuffs; too great an s of the dyewood or tannin mordant will cause the er to lose its character and in extreme cases to crack t. Bad shaving conduces to an imperfect finished t; the shavers' scratches showing prominently in the ed skin. Unsuitable neatfoot oil or bad fat-liquor ause a white cloudy scum to appear on the finished er; mould is sometimes caused by micro-organisms e egg yolk employed in fat-liquoring or through the y lying about in a wet condition during the process manufacture.

the discussion, J. W. Lamb stated that nitric and e acids cannot be used for stripping dyestuffs from er on account of their detrimental action on the leather —M. C. L.

ENGLISH PATENT.

e, Skins, Leather and the Like; Preparation for anising and Dyeing — F. J. Petersen, Copenhagen, Denmark. Eng. Pat. 19,323, Sept. 7, 1904. Under ternat. Conv., Sept. 9, 1903.

SEPARATION for use in cleaning and dyeing leather, s and tanned skins is made by dissolving stearic acid in benzene," or other hydrocarbon, adding a concen- d solution of alkali, alkali carbonate, or bicarbonate her with a dyestuff insoluble in water. For example, "azine" (100 parts) is shaken up with concentrated azone (5 to 20 parts); stearic acid (3 to 6 per cent.) ded, together with a suitable dyestuff, e.g., Nigrosine elck gloves. Lanoline may be added to the com- in order to increase the natural softness and bility of the leather.—M. C. L.

VII.—ACIDS, ALKALIS, AND SALTS.

Hargreaves Process [for Manufacture of Hydrochloric cid]; A Study of the — W. Staedel. Chem. Ind., 1905, 28, 173—178, 198—204, 226—232.

T author has made an attempt to elucidate the nature of e reactions occurring in this process, by means of labora- e experiments. In the equation representing the ult-

mate result of the process: $4\text{NaCl} + 2\text{SO}_2 + \text{O}_2 + \text{H}_2\text{O} = 2\text{Na}_2\text{SO}_4 + 4\text{HCl}$, 9 molecules take part. It is, therefore, to be expected that the reaction occurs in a 2:1

Influence of Temperature and Concentration.—M. A. of the reacting gases of known composition were passed over salt heated in a tube, the temperature being ascer- tained by a thermoelectric pyrometer, and the speed of reaction was measured by the amount of sulphur dioxide which disappeared. Below 150° C. the reaction was very slow, but about that temperature it increased rapidly in speed. The concentration of sulphur dioxide had a marked influence upon the speed of reaction, as had also that of the water vapour, whilst dilution of the gases by nitrogen had but little effect, and increase of the proportion of oxygen was equally without influence. It would almost appear from these results that the sulphur dioxide and water together decompose the salt with formation of sulphite, which at the moment of its formation becomes converted into sulphate.

Action of Sulphur Dioxide and Water Vapour on Salt.—A number of experiments, in which sulphur dioxide and steam in various proportions were led over heated salt, showed that a certain small amount of sulphite was formed, and that the issuing gases contained hydrochloric acid. Quantitative measurements led to the conclusion that equilibrium was attained when the volume of hydrochloric acid in the gaseous atmosphere was about 0.002 of the volume of sulphur dioxide. This was confirmed by the converse experiment of passing hydrochloric acid gas over heated sodium sulphite, when the issuing gas always contained a corresponding amount of hydrochloric acid. The latter results were somewhat irregular, but the irregularities were traced to the fact that the sulphite at the temperatures employed decomposes to some extent according to the equation $4\text{Na}_2\text{SO}_3 = 3\text{Na}_2\text{SO}_4 + \text{Na}_2\text{S}$.

Formation of Sulphuric Acid at 450° C.—Sulphur dioxide, air or oxygen, and water vapour, were passed through a tube containing pumice, in fragments similar to those of the salt in the former experiments, heated to 450° C. No formation of sulphuric acid occurred, and the condensed sulphurous acid in the latter part of the apparatus showed no oxidation. The author attributes this to the rendering of the oxygen inactive, first, through the storage of the gases over paraffin oil, and, second, through its having been strongly heated. Direct experiments, in which atmospheric air and oxygen, before and after being heated, were led through aqueous solution of sulphur dioxide, showed a marked oxidation by the heated gas, while that which had been heated was almost without action. As the oxygen entering into reaction in the Hargreaves process has been strongly heated in the pyrites burners and again in the first sulphate cylinder, the author considers it highly improbable that the direct formation of sulphuric acid occurs.

Behaviour of Sodium Sulphite towards Heat and Oxidation.—The decomposition of sodium sulphite into sulphate and sulphide, mentioned above, was studied. Rise of temperature greatly favours this reaction, though it occurs at so low a temperature as 180° C. Dry sodium sulphite, however, does not undergo this reaction at all: the presence of water is necessary. This acts possibly by hydrolytic decomposition: $\text{Na}_2\text{SO}_3 + \text{H}_2\text{O} = 2\text{NaOH} + \text{SO}_2$ (aqueous solution of sulphite, when merely warmed, becomes alkaline to phenolphthalein), and the sulphur dioxide so formed reacts on more sulphite: $3\text{Na}_2\text{SO}_3 + \text{SO}_2 + \text{H}_2\text{O} = 3\text{Na}_2\text{SO}_4 + \text{H}_2\text{S}$. It is impossible to say how far this reaction occurs in the Hargreaves process, but it seems very probable that it does occur, especially when the supply of oxygen is short. The avidity with which sodium sulphite absorbs oxygen was shown by passing moist air over sodium sulphite heated in a bath of sulphur vapour; though each small quantity of air could only have been in contact with the sulphite for little over a second, the air after passing over the sulphite contained only 1–2 per cent. of oxygen. Clearly, then, if sulphite be formed at all in the Hargreaves process, its immediate oxidation to sulphate will follow at once. Raschig has already drawn attention (this J., 1904, 338) to the rapid oxidation of sulphite at the moment of its formation.

Softening Temperature of Mixtures of Sodium Sulphate

and Chloride.—The occasional melting of the salt in the Hargreaves process, with consequent loss of porosity and stoppage of the reaction, is one of the important practical difficulties of the process. It has been attributed to the formation of bisulphate; but this implies the direct formation of sulphuric acid, which, if the author's views based on the above experiments be correct, does not occur. Moreover, though bisulphate fuses far below the temperature of the Hargreaves process, yet it decomposes so rapidly at that temperature that its formation in any quantity is from this point of view, too, highly improbable. The author has investigated the freezing-points of mixtures of sodium sulphate and chloride, and finds that the temperature at which crystals begin to separate from the fused mass is lower as the mixture departs further from pure sulphate or pure chloride, but that no mixture has a constant freezing point save $\text{Na}_2\text{SO}_4 + \text{NaCl}$ which behaves like a eutectic, and melts or solidifies at 610°C . Any mixture of the two salts containing fairly considerable proportions of either will begin to melt at this temperature when heated, and will become the more nearly fluid as its composition is nearer that of the eutectic. Actual experiment showed that mixtures containing 50, 70 and 85 per cent. of sulphate did soften at or very little above this temperature. The importance, then, of controlling the temperature of the process is obvious, for if it rise beyond 610°C , this softening will occur, while if it fall below 500° – 550°C , the speed of reaction diminishes too seriously for the process to be carried on.—J. T. D.

Hydrofluoric Acid.—I. E. Deussen. *Z. anorg. Chem.*, 1905, 44, 300–340.

HAVING regard to the increasing technical application of hydrofluoric acid, the author has carried out a full investigation of the acid with regard to its electric conductivity, and its influence on the inversion of cane sugar. The work is treated under the following headings:—Preparation of pure hydrofluoric acid; determination of the strength of hydrofluoric acid solutions; inversion of cane sugar by hydrofluoric acid (by the neutralisation method); conductivity of hydrofluoric acid solutions; rate of inversion by dilute hydrofluoric acid solutions; influence of temperature on rate of inversion by hydrofluoric acid; influence of neutral salts on the course of inversion by hydrofluoric acid; influence of sulphuric and silicofluoric acids on inversion by hydrofluoric acid; scheme for the preparation of a table showing the proportions of sulphuric and silicofluoric acids in hydrofluoric acid; examination of Spöhr's statements on the rate of inversion by hydrofluoric acid; inversion experiments by direct determination. The results show that hydrofluoric acid behaves as a slightly weaker acid than phosphoric acid of equal concentration. In its influence on the inversion of cane sugar, it appears to occupy a position between a monobasic and a dibasic acid. A N/2 solution of ammonium fluoride was found not to cause any inversion of a 25 per cent. solution of cane sugar at 25°C . A S.

Perstannic Acid and Perstannates. S. Farnar. *Ber.*, 1905, 38, 1184–1186.

HYDRATED stannic oxide, precipitated by sodium hydroxide from stannic chloride, and thoroughly washed, is mixed with excess of hydrogen peroxide, and dried, first on the water-bath at 70°C , finally in a desiccator. The dry powder has the composition $\text{HSnO}_4 \cdot 2\text{H}_2\text{O}$; it slowly loses oxygen and water, and is gradually decomposed by water into stannic hydroxide and hydrogen peroxide; when dried at 100°C , its composition is $\text{H}_2\text{SnO}_7 \cdot 3\text{H}_2\text{O}$.

Potassium perstannate, $\text{KSnO}_4 \cdot 2\text{H}_2\text{O}$, is formed by adding excess of hydrogen peroxide to solution of potassium stannate, cooling to 0°C , and adding alcohol. Sodium perstannate is similarly obtained. It is much less soluble in water than the potassium compound. Both salts lose oxygen when heated and are slowly decomposed by water into stannate and hydrogen peroxide. Their solutions give precipitates with the salts of barium, strontium, magnesium, zinc, nickel, cobalt, and platinum, which are mixtures of perstannate and hydroxide. The

lead salt, dried in the desiccator, rapidly loses oxygen and leaves lead peroxide; there is thus no doubt that it is a perstannate.—J. T. D.

Carbonates; Causticising of Alkali.—G. Bodli. *Z. Elektrochem.* 1905, 11, 186–187.

As a typical case the reaction can be represented by the following equation:— $\text{K}_2\text{CO}_3 + \text{Ca}(\text{OH})_2 \rightleftharpoons \text{CaCO}_3 + 2\text{KOH}$. The conditions necessary for progress of the reaction in the direction from left to right are discussed by the author by considering the various factors on which equilibrium depends. The greater solubility of calcium hydroxide, as compared with calcium carbonate, is the cause of the reaction, but calcium hydroxide is less soluble in caustic solutions than in pure water; similarly, calcium carbonate is less soluble in an alkali carbonate solution than in pure water. With increasing causticisation the two solubilities approach each other and are equal under the conditions of equilibrium. Expressing the solubility products by $\frac{\text{Ca}}{(\text{OH})_2} = K_1$ and $\frac{\text{Ca}}{\text{CO}_3} = K_2$ respectively

the above fact is represented by $\frac{(\text{OH})^2}{(\text{CO}_3'')} = \frac{K_1}{K_2} = K_3$; that

say, at a fixed ratio between the square of the hydroxide ions and the carbonate ions the equilibrium is attained. Direct experiment confirms the fact that the alkali carbonate concentration is approximately proportional to the square of the alkali concentration. By the use of barium or strontium compounds, it is possible to carry the causticisation further, since their hydroxides are more soluble and their carbonates less so than the calcium salts. The calculated values are as follows at 18°C .:—For calcium $K_1 = 3.10^{-5}$, $K_2 = 1.7.10^{-8}$, $K_3 = 2.10^3$; for strontium $K_1 = 8.6.10^{-4}$, $K_2 = 0.5.10^{-8}$, $K_3 = 2.10^5$. The values of K_3 found experimentally for calcium differ, however, considerably from those calculated, which is probably due to the physical condition and solubility of the carbonate which is obtained, differing from that of the calc spar.—R. S. H.

Lead and Silver Carbonates; Different Applications of Watt's Principle to the Dissociation of the Carbonates. A. Colson. *Comptes rend.* 1905, 140, 865–867.

THE decomposition of lead and silver carbonates into oxide and carbon dioxide is not a reversible reaction, owing to the polymerisation of the metallic oxide, so that it can be made so by allowing the change to go on in a closed atmosphere. In the latter case allowance must be made in the determination of the dissociation pressure for the presence of aqueous vapour by cooling the manometer with ice. The presence of moisture greatly accelerates the dissociation of carbonates of these metals on heating.—B. J.

Cupric Sulphide; Solubility of — in Alkali Sulphides. A. Rössing. *Z. angew. Chem.*, 1904, 57, 465–466.

HASSELDIETTER (see this J., 1905, 292) has quoted the author as saying that when a fusion of copper salt, alkali carbonate and sulphur is dissolved in water, practically all the copper is left in the residue. The author's statement was that under these circumstances practically all the copper goes into solution, and that when the solution is acidified, there is precipitated, along with sulphur, a copper sulphide of formula Cu_2S_6 .—J. T.

Manganese Borides; Preparation and Properties of the Borides. E. Wedekind. *Ber.*, 1905, 38, 1228–1232.

WHEN manganese is allowed to combine with boron by Goldschmidt's thermite method, a di-boride MnB_2 is obtained. In practice 95 grms. of boron are placed in a crucible and well pressed down; 87 grms. of manganese thermite are then added, and the mixture fired in the usual way. A regulus is obtained which is purified by powdering and treating with chlorine gas, when any unchanged boron is converted into chloride, and can be removed by boiling with water. The boride is very stable, but dissolved by acids, boron trihydride is evolved. Alkali it yields a mixture of borate and manganese

When heated on platinum foil it melts with partial oxidation. The powdered material pressed into blocks is a conductor.

Mono-boride can be obtained by reducing manganese (Mn_2O_3) in the electric furnace with boron. Purification being effected as described above. This compound possesses somewhat similar properties, but is decomposed on melting. If the elements be mixed in the electric furnace the mono-boride is obtained, but in a state very difficult to purify.—B. J. S.

Oxygen; Withdrawal of — by Platinum. R. Lucas. Z. Elektrochem., 1905, 11, 182—185.

Absorption of oxygen by platinum at temperatures above 650°C . led to the belief that oxygen forms a compound with this metal of some different constitution to that investigated by L. Wöhler (Ber., 1903, 36, 3475), this latter is only stable up to 460°C . The present experiments show that the absorption begins about 50°C , and increases rapidly up to about 1000° then goes off again. It has been found, however, that the action is entirely due to the small content of iridium (5 per cent.) which ordinary platinum possesses; the metal heated in oxygen to 500° — 900°C . showed no action. This result is of particular importance in connection with work with Geissler and other vacuum tubes. (See also this J., 1904, 1147; 1905, 195).—R. S. H.

Nitrogen; Preparation of Pure — from Nitrous and Nitric Oxides and Ammonia. G. P. Baxter and C. H. Key. Amer. Chem. J., 1905, 33, 300—304.

Nitrous and nitric oxides when mixed with ammonia ignited, combine with the latter gas to form nitrogen water:—

In the case of nitrous oxide, the reaction takes place with great explosive violence, but with nitric oxide, it is necessary to heat the mixture to a high temperature in the presence of a catalytic agent. Preparation of nitrogen nitric oxide.—A regular stream of nitric oxide is obtained by allowing nitric acid of sp. gr. about 1.2 to run on to copper turnings or on to iron turnings mixed with a few small pieces of platinum. The gas is led through a washing-bottle containing a strong solution of ammonia, and then through a hard glass tube containing 4-inch rolls of copper gauze (or platinised asbestos) heated by a combustion furnace. The nitrogen is then passed over water or dilute acid. The ammonia solution must not be allowed to become weaker than corresponds to sp. gr. 0.92. Preparation of nitrogen from nitrous oxide.—Nitrous oxide prepared from ammonium nitrate is passed into nitrogen and oxygen by passing it through a hard glass tube containing a 2-inch plug of platinised asbestos heated to dull redness. The gases are then passed through a wash-bottle containing a strong solution of ammonia, and finally through a second hard glass tube containing a plug of platinised asbestos heated to redness.—A. S.

FRENCH PATENTS.

Nitric Acid and its Compounds; Electrical Process for the Manufacture of —. Westdeutsch. Thomasphosphat-Werke G. m. b. H. Fr. Pat. 348,189, Nov. 22, 1904.

OXIDES of nitrogen are produced by exposing a mixture of nitrogen and oxygen to the electric discharge, the power used being less than 200 watts. The gaseous product is then treated with water or an alkali in the usual manner. It is claimed that by working with less than 200 watts, a product is obtained containing less than 50 per cent. of nitrous acid and its compounds.—A. S.

Alkali Carbonates, Hydroxides, and Polysulphides; Simultaneous Manufacture of —. P. Cernian. Fr. Pat. 347,927, Jan. 22, 1904.

SODIUM sulphate, obtained from the chloride by the usual process, is ground with bituminous schist softened by heat, with which it is formed into briquettes. These are arranged in a furnace of the type of a cement furnace, with anthracite coal, in such a manner that there may be no contact between the briquettes and the furnace walls, the briquettes being also separated from each other by fuel. After furnacing, the briquettes are withdrawn and sorted according to the heat (known by the appearance) to which they have been subjected, in some sodium carbonate and polysulphide being formed, whilst others

contain caustic soda and the polysulphide. Potassium sulphate may replace sodium sulphate in the process.—E. S.

Ammonia; Extraction of — from Gas Fluids, by Dry Distillation. Soc. F. Brunck. Addition to Fr. Pat. 331,077 of April 9, 1903. *Ill.*, page 432.

Metal Sulphates and other Salts; Production of — from Metal Sulphides and Sulphide Ores containing Iron. O. Meurer. Fr. Pat. 347,970, Nov. 16, 1904.

A CRUSHED metal sulphide, sulphide ore or matte is mixed with from 10 to 15 per cent. of an alkali or alkaline earth sulphide or polysulphide, and the mixture heated in a closed chamber. The product, after disintegration by exposure to the atmosphere, is washed, and the salts thus extracted are recovered from the solution for re-use. The residual mass is dried, powdered, and exposed to the air in a (preferably) heated chamber, to undergo oxidation with the formation of sulphates. In case insufficient iron monosulphide is present in the material to transform all the metals into sulphates, the metal oxides finally remaining may be dissolved in a suitable acid. (Reference is made to Fr. Pat. 295,379 of Dec. 18, 1899, and to an Addition thereto of March 24, 1902. Compare Eng. Pat. 26,668, of 1903; this J., 1904, 1027; and U.S. Pat. 733,590 of 1903; this J., 1903, 908.)—E. S.

Air and Gaseous Mixtures; Separating — into their Elements. Soc. L'Air Liquide (Soc. Anon. pour l'Étude et l'Exploit. des Procédés G. Claude) et R. J. Levy. Second Addition, dated Nov. 4, 1904, to Fr. Pat. 338,842, of June 3, 1903. (This J., 1904, 823.)

IN the system described in the main patent and first Addition thereto (this J., 1904, 1216), for producing oxygen by means of the methodical washing of a gaseous mixture of oxygen and nitrogen by liquid air, or by a liquid mixture of oxygen and nitrogen. The present Addition consists in increasing the yield of oxygen by the injection of atmospheric air, or of other mixtures of oxygen and nitrogen, into the rectifying apparatus. (Compare also Fr. Pat. 338,964, of 1903; this J., 1904, 1028.)—E. S.

GERMAN PATENTS.

Potassium-Magnesium Carbonate; Decomposition of the — formed as an Intermediate Product in the Manufacture of Potassium Carbonate by the Magnesia Process. Deutsch. Solvay-Werke, A.G. Ger. Pat. 157,354, May 29, 1903. Addition to Ger. Pat. 135,329, Oct. 6, 1901.

ACCORDING to Ger. Pat. 135,329, the potassium-magnesium carbonate was decomposed by means of the theoretical quantity of magnesia according to the equation:

It has now been found that if the temperature be maintained at not above 20° C., an excess of magnesia can be used, without any basic magnesium carbonate being formed. The use of an excess of magnesia ensures the complete decomposition of the potassium-magnesium carbonate.—A. S.

Ammonia; Synthetic Preparation of —. Westdeutsch. Thomasphosphat-Werke, G.m.b.H. Ger. Pat. 157,287, Sept. 12, 1901.

A MIXTURE of hydrogen, nitric oxide, and carbon monoxide is subjected to the action of a contact substance such as spongy platinum or the like. The temperature is not allowed to rise above 80° C., and the reaction is accelerated by subjecting the gaseous mixture to the silent electric discharge. In practice the gaseous mixture would consist of Dowson gas or water-gas and nitric oxide. A mixture containing 12 parts by volume of hydrogen, 40 of nitric oxide, 44 of carbon monoxide and 4 of carbon dioxide yields on the average about 10 per cent. by vol. of ammonia.—A. S.

Lixiviating Apparatus for Salts. R. Sauerbrey. Ger. Pat. 155,729, July 1, 1903.

THE apparatus consists of two or more troughs provided

with Archimedean screws, and connected at one end chambers at the side. The salt to be dissolved is introduced into the trough at the end where the concentrated solution is discharged. The particles of salt carrying the outflowing concentrated solution into the side-chamber connected to the first trough, are caused to pass into a channel through which the incoming liquid flows, are carried along by the latter into the side-chamber connected to the second or last trough, whereby any so compounds in these particles are dissolved.—A. S.

VIII.—GLASS, POTTERY, AND ENAMEL.

Glass; Studies on Coloured —. A. Lecrenier. Soc. Chim. Belg., 1904, 18, 395—403.

THE authors divide colouring materials into three varieties according to the way in which they act on glass, direct colouring materials, "saturation," and "cementation" colouring materials. Direct colouring materials which include cobalt sesquioxide, nickel oxide, ferric ferrous oxides, cupric oxide, chromium sesquioxide trioxide, manganese protoxide and sesquioxide, vanadium trioxide, and sulphides and selenides of a and alkaline earths, produce a colour, the intensity of which depends only on the proportion of material present and the kind (e.g., soda or potash glass used). With "saturation" colouring materials such as cuprous oxide, gold and silver salts, antimony oxide, phosphates, arsenates and fluorides, the colour generally depends only on conditions of temperature when more than a certain minimum proportion of material is present; below this minimum no colour is produced. Thus, cuprous silicate being colourless, conditions must be such that red cuprous oxide is set free if the colour is to be produced. With gold, the colour depends on the size of the particles of metallic gold deposited, the substances producing opalescence, such as phosphorus &c., a certain minimum amount must also be present, otherwise the glass remains clear. "Cementation" colouring materials are applied by mixing them with silver chloride, sulphide, chromate or phosphate, covering the surface of the polished glass with the mixture and heating to a temperature below the softening point for some time. After cooling, the surface of the glass is washed with water; the glass takes up the colour to a certain depth without losing its brilliance. Red glass gives a yellow colour in this way; a red colour is produced by means of cupric oxide, the glass being heated first in an oxidising and then in a reducing atmosphere.

When several colouring materials are present in the same glass, molecular changes take place till equilibrium is established. This state is determined not only by the temperature to which the glass is heated, but also by the pressure and by the action of light. Thus, if a glass containing ferrous silicate, manganic oxide is annealed, and the glass cooled quickly, the rose-red colour of manganic silicate is produced. If the glass be reheated and cooled slowly, this substance is reduced, and a colourless glass results, which on exposure to intensely actinic light, or to X-rays, again becomes rose-red, owing to the oxidation of the manganous silicate at the expense of the ferric compounds formed during the reheating. Similarly if glasses containing an oxide of a heavy metal, such as lead, and an alkali sulphide be quickly cooled, the colour due to the alkali sulphide is produced; if, on the other hand, they are slowly cooled, they become black from the formation of the sulphide of the heavy metal.—A. G.

Analytical Methods used at the Val-Saint-Lambert Works. A. Lecrenier. XXIII., page 458.

Ceramic Products; Determination of Melting-point of —. J. Bronn. Z. angew. Chem. 1905, 18, 460—2.

THE apparatus of Heraeus (this J., 1905, 133), as help itself points out, is far too costly ever to come into general use. The author uses a tube of fireclay, magnesia, or other refractory material, 70 mm. diameter, which is supported in a channel of fireclay strengthened outside by sheet iron, somewhat shorter than the tube. The space

en the tube and channel is packed with "kryptol," suitable electrodes are provided to transmit a current—100 amperes at 100–120 volts. The heating of the is effected as gradually as possible, partly by regulating the current by means of a resistance, partly by turning off for short periods till temperature-equilibrium between kryptol and tube is approximately reached. With 81 amperes at 110 volts, Seger cone 38 is melted, while cone 39 is unaffected; and with the practice the temperature can be regulated and practically constant for some time. Apparently furnace works equally well with continuous or alternating current; it lasts for a long time, and the tubes and about 10 alternate heatings (up to cone 30) and so on. At higher temperatures they do not last so long, twelve to fifteen Seger cones can be heated at once in the furnace. For the highest temperatures unglazed must be employed, which are porous to the reducing gas generated in the furnace; for most things requiring very high temperatures, however, this reducing gas is in no way objectionable.—J. T. D.

Glass; Use of — in Chemistry. Berthelot. XXIII., page 457.

Vessels; Use of — in the Laboratory. F. Mylius and A. Meusser. XXIII., page 457.

GERMAN PATENTS.

Al-Glass; Production of White Lime or Lead —. L. Bock. Ger. Pat. 157,135, Sept. 18, 1902.

Charge is mixed with an alkali sulphate which, on forming a covering layer protecting the molten glass from the injurious action of the fire-gases. The amount of alkali sulphate added is about $\frac{1}{10}$ th— $\frac{1}{2}$ th of the amount of alkali carbonate in the charge.—A. S.

Wool; Process of Drying —. B. Thomans. Ger. Pat. 156,475, Feb. 7, 1902.

Wools before burning are dried by being heated in a chamber and simultaneously exposed to superheated steam at a temperature of 160°–400° C. It is found that by the use of steam instead of air, the drying proceeds rapidly and uniformly, and no cracks are formed on the surface of the goods.—A. S.

X.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

Firebrick and Dinas Brick in the Construction of Retort Faces. F. Leisse. J. f. Gasbel., 1905, 48, 257–261.

A great drawback to the use of firebrick in the construction of retort furnaces is its high coefficient of contraction when exposed to high temperatures, the shrinkage being 5–7 per cent. at 1300° C. This and the tendency to warp when heated, quickly lead to deformation of the retorts. The same defect of shrinkage also attaches to shales with a large percentage of clay (Rakonitz and Leurode shales); whilst bauxite contains too large a portion of iron and titanate acid to be suitable for the purpose. On the other hand, Dinas brick, which consists of 95 per cent. of silica, 2–3 per cent. of alumina, iron oxide, and 1–2 per cent. of lime, withstands higher temperature than firebrick, and increases slightly in volume, the linear expansion in good samples being 3.4 per cent. at 1700° C. (14 days' exposure). Moreover, the furnaces built of this material at Cologne are found to bear fluctuations of temperature very well; and the walls can be built thinner than when firebrick is used, the larger combustion chambers thus possible facilitate the utilisation of heat. (Pyrometric tests show the superiority of 70° C.) Though Dinas brick is more expensive than firebrick, it is less corroded by flying ash and other chemical agents; and there is no cracking of the pillars

as with firebrick, the heat being more uniformly distributed through the mass, although the granular structure and porous character of the material have given rise to the view that it is a bad conductor of heat. As a matter of fact its conductivity is about 20 per cent. higher than that of the best firebrick, this quality being apparently due rather to the relative percentage of silica and alumina than to the structure. To secure these results, however, it is essential that the Dinas brick should be of the highest possible quality, and the furnaces constructed with the greatest care.—C. S.

ENGLISH PATENTS.

Asphalt, Artificial; Manufacture of — or of the like Composition. J. J. Shedlock, Colchester. Eng. Pat. 5712, March 8, 1904.

LIME, or other suitable material, such as limestone, is mixed with tar or similar material, and the finely-divided mixture is subjected to the action of steam or inert gas, such as carbon dioxide or nitrogen, at a temperature of from 300° to 500° F. The more volatile constituents of the tar, &c., are driven off in this manner, leaving a mixture which may be used like ordinary asphalt. The treatment with steam or gas is carried out in a closed chamber, into which the mixture is fed at the top, and in which it falls from one of a number of horizontal trays to the next. Each tray has a perforation, through which the mixture is caused to fall as it is moved around on the tray by a scraper revolved by a centrally-placed axle. The superheated steam or gas enters the chamber through a pipe having one outlet between every two trays. Suitable arrangements are made to condense the volatile constituents.—A. G. L.

Plaster of Paris; Manufacture of — and Apparatus therefor. W. Brothers, Prestwich, Lancs. Eng. Pat. 5853, March 10, 1904.

Gypsum is treated with steam at a temperature of about 250° F., until it becomes converted into plaster of Paris, which is then further dried at a temperature not below 170° F., by means of steam. For this purpose the gypsum is placed in a hollow revolving chamber, fitted with an outer jacket, into or through which steam is admitted from the hollow trunnions on which the chamber revolves. If the gypsum is treated directly with the steam, a fixed pipe is also placed in the chamber which always supplies steam at the top of the chamber. During the final drying operation, steam is only admitted into the outer casing. The gypsum may be ground before or after the treatment.—A. G. L.

Stone, Artificial; Manufacture of — in Imitation of Marble or Granite and the like. L. Lefranc, Lausanne, Switzerland. Eng. Pat. 9769, April 28, 1904.

SEE Fr. Pat. 328,262 of 1903; this J., 1903, 952.—T. F. B.

Wood, and Goods of different kinds, and for Drying such Goods; Impts. in Heating, Steaming, and Chemically Treating —. C. McWhirter, London. Eng. Pat. 14,869, July 2, 1904.

THE boiler in which the material is to be treated (creosoted, for instance) is surrounded by a steam-jacket. The steam-jacket is surrounded by an outer jacket, leaving a space between the two, through which air is circulated, and which is connected, either to an adjacent drying chamber, or to the boiler itself, if it is desired to use that as a drying chamber. In this way the hot air required for drying or disinfecting is heated by the steam which serves also to heat the boiler. The material may be treated in the boiler, and then removed to the adjacent drying chamber, or it may be dried in the boiler by connecting it with the air-jacket.—W. H. C.

Dust; Prevention and Laying of —. W. M. Sandison, Ayton, N.B. Eng. Pat. 18,904, Sept. 1, 1904.

ROAD surfaces are treated, by sprinkling or saturating, with the soap suds obtained from wool washing, which are previously mixed with a suitable, preferably disinfectant, oil or grease, such as creosote. Suds from which

the grease has been partly removed, or which have been partly deprived of potassium salts may be used; in the last instance, a deliquescent salt is added. For transport purposes the solids may be evaporated to lessen their bulk.

A. G. L.

UNITED STATES PATENTS.

Wood-Filler. S. D. Kudysch, Philadelphia. U.S. Pat. 782,252, Feb. 14, 1905.

A PULP-LIKE "filler" for rubbing into wood, is obtained by combining a volatile liquid with the coloured residuum produced in the manufacture of acetic acid from calcium acetate. The residuum is ground with water, neutralised with milk of lime or of baryta, dried, and is then mixed with the volatile liquid, which may be, for instance, water, alcohol, benzine, or turpentine. E. S.

Refractory Articles; Process of Manufacturing — P. Klein, Riga, Russia. U.S. Pat. 784,624, March 14, 1905.

PURE aluminium hydroxide $Al_2(OH)_6$ is mixed with from 10 to 80 per cent. of pulverised quartz, moulded, pressed and burned, thereby yielding a new refractory article, consisting of aluminium silicate containing upwards of 42 per cent. of alumina.—W. C. H.

Colouring Natural Compact Crystalline Stones; Process of — A. Waltze, Assignor to Chem. Techn. Fabr. Dr. A. R. W. Brand und Co., Charlottenburg, Germany. U.S. Pat. 786,082, March 28, 1905.

SEE Eng. Pat. 5594 of 1903; this J., 1904, 488.—T. F. B.

FRENCH PATENT.

Bricks, Artificial Stone, and Similar Products; Process of Making — L. F. Kwiatkowski. Fr. Pat. 347,918, Nov. 15, 1904.

SEE U.S. Pat. 775,222 of 1904; this J., 1904, 1217.—T. F. B.

GERMAN PATENTS.

Stone, Tubes, Retorts, Muffles, &c.; Manufacture of Refractory — and of Fireproof Coatings on Ceramic Objects. O. Pufahl. Ger. Pat. 156,756, Dec. 24, 1902.

CLAIM is made for the use of the rare earths or their mixtures or compounds as constituents of the raw mixtures for the production of artificial stone, retorts, &c., and as a refractory coating on ceramic objects.—A. S.

Colour [for Stone, &c.]; Preparation of a Facing — Gogolin-Gorasdzor Kalk- u. Zement-Werke. A.G. Ger. Pat. 156,597, Aug. 26, 1903.

BURNT clay or the like is ground, digested with hydrochloric acid, and the chlorine compounds removed by washing with water. The pigment produced is mixed with about 25 per cent. of cement, and sufficient water to form a paste, which is applied to the object to be coloured.—A. S.

Asbestos Objects from finely-divided Asbestos; Preparation of — without the use of Binding Agents. J. Bernfeld. Ger. Pat. 156,794, Feb. 17, 1904.

THE present patent is an addition to Ger. Pat. 148,936 (see Eng. Pat. 16,493 of 1901; this J., 1902, 1143). The objects before being heated are treated with acids to increase their strength and resistance to acid.—A. S.

X.—METALLURGY.

Steel, Chrome-Vanadium; Heat Treatment of — H. R. Sankey and J. R. Smith. Inst. Mech. Eng., Dec. 16, 1904. Engineering, 78, 871—877.

THE authors examined the effects of different heat-treatments on a chrome-vanadium steel containing:—carbon, 0.297; silicon, 0.059; manganese, 0.394; chromium, 1.066; and vanadium, 0.169 per cent. The steel as cast showed, after rolling, a yield-point at 36.9 tons per sq. in.;

ultimate stress, 54.1 tons; elongation, 24 per cent 2 ins.; and contraction, 44.2 per cent. The heat-treatments were:—Annealing for half an hour at 500°, 690°, 800°, 900° and 1100° C.; soaking for 12 hours at 500°, 620°, 690°, 800°, 900°, and 1200° C.; water quench from 500°, 690°, 800°, 900° and 1200° C.; oil quench from 500°, 690°, 800°, 900° and 1200° C.; oil quench from 500°, 690°, 870° and 1000° C. with reheating 6 mins. at 350° C.; oil quenching from 690° and 90° with reheating for 10 mins. at 600° C. Apparently the only critical point in the cooling of the steel was 710°—715° C., and only the treatments at temperatures higher than this produced marked changes in the results of the mechanical tests. The yield-point and breaking were considerably reduced, the elongation and contraction slightly increased, and the impact figure (work absorbed in producing fracture at one blow) greatly increased by annealing and by soaking at 800° C. and higher temperatures. Annealing at 900° C. produced, on the whole, the best results. The steel was spoiled by quenching in oil from 800° C. Quenching in oil caused a great reduction in the impact and bending test figures. It was found that heat treatment had a greater effect on the results of impact tests than on those of the tensile tests. Chrome-vanadium steel is less sensitive to heat-treatment than carbon steel. A spring made of a steel containing same proportions of chromium and vanadium as that described above, but 0.44 per cent. of carbon, was capable of bearing about twice as great a load as a good carbon steel spring, but the extension was about 7 per cent. greater with the chrome-vanadium steel. Chrome-vanadium steels which have been injured by overheating are restored to a considerable extent, by reheating to about 900° C.—A.

Metals; Oxidation of — in the Cold in presence of Ammonia. C. Matignon and G. Desplantes. Compt. rend., 1905, 140, 853—855.

VARIOUS metals were placed in closed flasks containing oxygen and a small quantity of ammonia, and allowed to stand for a number of hours. The amount of metal present in solution was determined in each case; cobalt, nickel, silver, cadmium, zinc, molybdenum, tungsten and mercury were all considerably oxidised, whilst chromium and vanadium were not attacked. In the case of mercury, the usual "Millon's" base is formed, especially when the metal is allowed to go on in absence of light.—B. J. S.

Iron Ores and Slags; Analysis of — R. Naess. XXIII., page 459.

Ferro-silicon; Determination of Carbon in — K. Jene. XXIII., page 459.

ENGLISH PATENTS.

Malleable Castings; Production of Iron suitable for the Manufacture of — A. Zenzen, Charlottenburg, Germany. Eng. Pat. 6,997, March 23, 1904.

THE process consists in preparing in a Bessemer converter white iron containing from 2 to 2.5 per cent. of carbon, 0.5 per cent. of silicon, and about 0.2 per cent. of manganese, but poor in phosphorus and sulphur. To this is added about half the quantity of an iron melted in a cupola furnace, of such composition, that after the reaction which occurs on mixing the two metals are complete, the white iron is produced containing 2.5 to 3 per cent. of carbon, about 0.5 per cent. of silicon, and 0.3 per cent. of manganese, the proportion of phosphorus and sulphur being very low.—R. S. H.

Iron and Steel; Manufacture of — B. Talbot, Leeds. Eng. Pat. 9110, April 20th, 1904.

A FURNACE having two or more hearths separated by bridges, is so arranged "that the heat and oxygen contained in the slag on the finished metal in one hearth," is utilised for the refining of the metal in another hearth by causing it "to boil over the bridge," or otherwise transferring it from one hearth to the metal in the other.—J. H. C.

Extraction of — from Solution in Water [See r]. H. C. Giantar and U. Giantar, London. Pat. 689, Jan. 11, 1904.

ter is forced through small delivery pipes into a receptacle containing mercury, so that the two are violently agitated together, and part of the r is "floured." The mercury should occupy one of the depth of the receptacle. When sufficiently l, the water and "floured" mercury are drawn a series of settling tanks in which the "floured" containing some gold separates, and is recovered her use.—J. H. C.

ast Furnace; Treating —, and Utilising the acts thereof. J. H. W. Stringfellow, Walthamstow. Pat. 5648, March 8, 1904.

orl is obtained as usual from the slag, and is then d to a process, by pounding, crushing and screening, arates from it the granular matter mechanically with it. This procedure is designed to separate into two parts, the siliceous wool and the non-granular matter. This latter may be utilised generation of gas for firing forges, driving gas- &c., by treatment with sulphuric acid, or it may for the recovery of ammonia from sewage, or for aral or other purposes.—A. UNITED STATES PATENTS.

Iron; Process of Purifying Pig —. J. B. Nau. York. U.S. Pat. 786,048, March 28, 1905.

pig-iron is poured upon a mass of broken pieces metallic ore in such a manner that it descends in eams through the spaces between the pieces of ore, ns a bath in which the ore is kept immersed for ed period, the molten purified metal being then ff. The process may be made continuous by the molten pig-iron into contact with the lower a body of ore, heating the upper part of the ore by means of the heat generated in the puri- e, drawing off the molten purified pig-iron and adding further quantities of molten pig-iron ver part and of ore to the upper part of the body A. S.

Process of Reducing —. D. R. Robertson. ile, Colo. U.S. Pat. 786,051, March 28, 1905.

ly-divided ore is heated and agitated with water ice of ammonia, potassium nitrate and rock-salt; bate, "iron-water" and nitric acid are then added mixture again agitated. After allowing to settle, eed metals are precipitated upon the ore pulp- tion, and the solid matter is drained, cooled, and dried, preparatory to smelting.—A. S.

separating and Refining Complex —. E. Hedburg. or to American Reduction Co., Chicago. U.S. 85,167, March 21, 1905.

s are dried, roasted, treated while hot with a hydrocarbon, partially cooled by an air-blast, t passed through magnetic fields of progressively t strength. In some cases lime is added to the e it is roasted.—J. H. C.

Roasting —. C. H. Repath and F. E. Assignors to F. Klepetko, New York. U.S. Pat. 7, March 21, 1905.

hearths are so arranged that there is always an earted body of material extending throughout the By means of a hollow central stirring shaft with rabbles, the material is continuously passed alternate central and marginal openings from o hearth until finally discharged at the bottom

of the furnace. The products of combustion from an external firebox are led to the lower hearth and thence pass to a discharge flue.—J. H. C.

FRENCH PATENTS.

Steel Furnace with Blast. C. B. M. Lancon. Fr. Pat. 348,074, Oct. 21, 1904.

This is essentially a Martin furnace provided with tuyères and so mounted that it may be turned on its longitudinal or transverse axis. The tuyères are so arranged that the blast may be made to play upon or beneath the surface of the bath at will. J. H. C.

Copper; Process for the Separation of —, particularly from Low-grade Ores. P. and A. Weiller. Fr. Pat. 347,840, Oct. 31, 1904.

The minerals are fused with suitable fluxes so as to form sulphides or silicates from which the copper is precipitated by iron.—J. H. C.

Gas, Blast-Furnace; System of Utilising —. P. L. Hulin. Fr. Pat. 348,177, Jan. 30, 1904. H., page 430.

GERMAN PATENT.

Zinc and Cadmium; Muffle for the Distillation of —. O. Unger. Ger. Pat. 156,342, July 31, 1903.

The furnace consists of two or more thin-walled muffles fitting one within the other, with, if necessary, spaces between. By the use of two thin-walled muffles, capable of free movement, instead of a single thick-walled one, strains during heating and cooling, and the formation of cracks are prevented.—A. S.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

(A).—ELECTRO-CHEMISTRY.

Nitrates to Nitrites; Electrolytic Reduction of —. E. Müller and F. Spitzer. Ber., 1905, 38, 1190—1194.

MÜLLER and Weber showed that nitrates are electrolytically reduced to nitrites when the cathode is coated with spongy copper, but as the continuance of the process renders the copper smooth and coherent, and thus favours the further reduction to ammonia, they were obliged from time to time to polarise the cathode anodically, and thus regenerate the spongy surface. The authors find that the same end is attained by mixing a copper salt with the electrolyte, and thus slowly depositing copper during the electrolysis. Working in this way with mixtures of nitrate and nitrite (much disturbance and irregularity arose in the earlier experiments through the use of nitrite containing a trace of lead), they find that in solutions already containing 30 per cent. of nitrite, further nitrite can be produced corresponding to 80 per cent. of the current used. Müller and Weber had shown that, working with a diaphragm, a loss occurred through the nitric acid set free at the anode destroying the nitrite in the pores of the diaphragm, and the authors therefore endeavoured to work without one. So long as a platinum anode was used, anodic oxidation of the nitrate occurred; but Bültmann, and, independently, Traube and Biltz, found that this was not the case with an iron anode. The latter investigators stated, however, that this oxidation did occur in presence of copper salts; but the authors have shown that want of hydroxyl ions, and not the presence of copper salts, was the cause of the oxidation observed by Traube and Biltz, and they have found that a reduction of nitrate to nitrite corresponding to 84 per cent. of the current used can be kept up for long periods in a solution already containing 36 per cent. of nitrite, without a diaphragm, if the copper precipitated on the cathode be renewed in the solution.—J. T. D.

Copper Sulphide; Electrolytic Behaviour of — G. Bodländer and S. Idaszewski. *Z. Elektrochem.* 1905, 11, 161—182.

With a view to studying the possibility of obtaining copper by the electrolysis of fused cuprous sulphide, the authors have carried out an extensive research on the electrical and other properties of this substance. Cuprous sulphide melts at 1091 C., and in the fluid condition can form intimate mixtures with metallic copper, but when the material solidifies the copper is thrown out. In accordance with the early work of Hittorf, but contrary to recent published work, it is found that the cuprous sulphide behaves as an electrolyte in the solid condition, but that its electrical conductivity at ordinary temperatures is very low. With increasing content of cupric sulphide both the power of conducting electrolytically, as also the low conductivity at ordinary temperatures gradually disappear since the cupric compound exhibits metallic conduction. As a consequence, when fused cuprous sulphide is submitted to electrolysis in a U-tube, the decomposition products are removed by depolarisation and, therefore, do not appear in the free state. Fused sodium sulphide has a decomposition voltage of 1.62, fused potassium sulphide one of 1.65. In the molten condition cuprous sulphide and sodium sulphide are miscible within certain limits, and the presence of a double compound (NaCuS) has been found by isolation of small steel-blue crystals of this composition. In the fused mixture on electrolysis, the copper migrates in the form of a complex ion to the anode, and copper is deposited at the cathode only by a secondary reaction. The practical preparation of copper by electrolysis of the fused sulphide, or of mixtures with the alkali sulphides, is, therefore, considered to be hopeless.—R. S. H.

ENGLISH PATENTS.

Heating by Electricity [Electric Furnace]; Impds. in — A. Voelker, Berlin. Eng. Pat. 10,873, May 11, 1904.

SEE FR. Pat. 343,094 of 1904; this J., 1904, 988.—T. F. B.

Poles or Electrodes of Electrolytic Apparatus [Electrolysis of Alkali Chlorides]. G. J. Atkins, Tottenham, Middlesex. Eng. Pat. 11,470, May 18, 1904.

THE trough-shaped carbon anode with concentric rotating cathode previously invented by the author (this J., 1901, 815), is modified in such a way that the anode takes the form of a hollow cylinder of carbon, almost entirely surrounding the rotating cylindrical cathode. An opening is left at the upper part for the escape of the gases evolved during electrolysis. By this means the cathode is completely immersed in the electrolyte, and the oxidation, caused by the alternate action upon its surface of the electrolyte and atmospheric air, is prevented.—R. S. H.

Grain and Rice; Process of Preparing a Solution for use in Bleaching — J. L. Lawson, Leith. Eng. Pat. 10,211, May 4, 1904.

A MIXTURE consisting of calcium chloride, 35 parts, borax, 2 parts, and boric acid, 1 part, is placed in a small perforated box fixed to the inside of a large tank constructed of non-conducting material such as wood or earthenware. The tank is then filled with water until, as the level rises, the small perforated box becomes half full. The ratio of water to mixture should be as 10:1. After passing steam into the tank and box until complete solution has been effected, an electric current is passed through the solution for from 30 minutes to one hour, during which time the steam pipes are removed. Steam is again passed into the tank to mix its contents, and the solution is then ready for the bleaching and purifying purposes referred to.—W. P. S.

Oleic Acid; [Electrical] Conversion of — into Stearic Acid and like Compounds. A. de Hemptinne. Eng. Pat. 1572, Jan. 26, 1905. XII., page 448.

UNITED STATES PATENTS.

Electric Furnace. W. C. Arsem, Schenectady, N. Y. Assignor to General Electric Co., New York. U. S. Pat. 785,335, March 21, 1905.

THE material to be heated is supported within a heat space enclosed by a helix of graphite, arranged within air-tight chamber, provided with a sight opening with means whereby it can be cooled. The helix of graphite, which serves as the heater, is surrounded by a double-walled screen of refractory material, the space between the walls being filled with a heat-insulating material. The ends of the helix are connected to tubular conductors, through which a cooling fluid can be circulated. Means are provided for exhausting the air and for introducing an inert gas into the outer chamber.—A.

Electrode for Electric Furnaces. E. F. Price, G. E. and J. G. Marshall, Assignors to Union Carbide and Carbon Co., Niagara Falls, N. Y. U. S. Pat. 785,832, March 28, 1905.

THE hood of the furnace projects downwards into the working chamber. In the top of the hood, which is provided with a cooling arrangement, are holes in which electrode-holders fit loosely, with a refractory luting packing. Each electrode consists of a number of graphite rods. Each holder has a water-chamber provided with a baffle, and in the chamber are a number of removable sockets threaded internally, into which the graphite rods composing the electrode fit. A refractory cement of relatively high resistance, with a support of perforated metal, is provided between and around the graphite rods, whilst the portion of each rod projecting into the working chamber is encased in a metal sheath, with a packing of carbonaceous cement between the rod and the sheath.—A.

de; Electrolytical Extraction of — from Solutions. F. Webb, London. Eng. Pat. 6832, March 21, 1904.

is made in electrolytic apparatus for the extraction of metals from solutions, of the combination of a graphite anode with a cathode of any suitable material (graphite). If the cathode is made of material other than graphite, it is coated on the surface with graphite. The electrodes are arranged within the apparatus at a distance from $\frac{1}{4}$ in. to $\frac{3}{4}$ in. apart.—A. S.

r-jackets, Casings and the like; Electrolytic Manufacture of —. A. F. Bosquet, Paris. Eng. Pat. 627, Sept. 24, 1904. Under Internat. Conv., Feb. 10, 1904.

invention relates to the manufacture of copper jackets for explosion motors, &c., by the electrolysis of copper, and is similar to the previously published method of the same inventor (this J., 1904, p. 1). The space for the water is occupied by a material as gutta-percha or wax, coated with graphite, which is melted out after the copper deposit has reached the site thickness. The whole is enclosed in a perforated mould, which closes the orifices of the explosion motor, or other article on which the jacket is being made, but leaves sufficient space for the electrolyte to be in contact with those portions of the surface of the metal which are to receive the deposit.—R. S. H.

UNITED STATES PATENTS.

ls from Ores; Apparatus for Extracting —. A. Hendryx, Los Angeles, Cal. U.S. Pat. 785,214, Feb. 21, 1905.

apparatus consists of a tank with a conical bottom and internal partitions or ribs which are radially disposed; a circular spreader placed above the tank, a central pipe communicating with its lower part, suitably placed electrodes within the tank, apparatus for raising pulp, and discharge passage controlled by a valve. The ore pulp is placed in the tank, and portions of it are continuously raised from the bottom and discharged through the spreader so as to secure thorough action. The raised pulp then flows gently between the electrodes, a current being maintained the while.

—J. H. C.

ls [Aluminium] and Alloys; Process of Producing —. S. Blackmore, Mount Vernon, N.Y. U.S. Pat. 8185, March 28, 1905.

Alloy of aluminium and copper is produced by adding aluminium to a fused mass consisting of an oxide of a metal or metals having greater affinity for oxygen than aluminium or copper, and subjecting the mixture to the action of an electric current capable of reducing the aluminium and copper. Claim is also made for the process of reducing metal from substances containing the same, which consists in "exposing a fused metal-containing substance to the action of a metal-yielding electric current, while subjecting the fused substance to the action of a non-metal-yielding current passed through the same between electrodes at an angle to the path of the metal-yielding current, and one of which electrodes is in common with the metal-yielding-current electrode."—A. S.

Aluminium or other Metals; Process of Extracting —. S. Blackmore, Mount Vernon, N.Y. U.S. Pat. 6,244, March 28, 1905.

The process consists of electrolysis a fused mixture of one or more compounds composed of a single metal compound with fluorine and with different non-metallic elements

other than halogens, and, if desired, in presence of a substance capable of combining with one of the non-metallic elements. The E.M.F. used is insufficient to liberate fluorine, but is capable of liberating the less electro-negative non-metallic element or elements. For example, a fused mixture of aluminium fluoride and alumina is electrolysed with a carbon anode, whereby metallic aluminium is produced, together with oxygen, the latter combining with the carbon to form carbon monoxide. From time to time fresh alumina is added, and the reduced aluminium withdrawn.—A. S.

Metals [Zinc]; Process of Electrodepositing —. E. D. Kendall, Brooklyn, N.Y. U.S. Pat. 786,221, March 28, 1905.

It is claimed that metallic zinc is deposited in the form of a hard, adherent coating on surfaces of iron, steel or other metal by passing an electric current between a cathode consisting of the metal to be plated, and a suitable anode in an electrolyte containing zinc sulphoglycerate.—A. S.

GERMAN PATENT.

Iron Objects; Electrical Process for the Case-Hardening of — by means of a Resistance-Mass of Granulated Charcoal. Kryptol-Ges. m. b. H. Ger. Pat. 156,232, Feb. 12, 1903.

The portions of the iron object to be case-hardened are brought into contact with the resistance-mass, and the latter is connected to a source of electricity. For the cementation of soft iron, a box is used of which two opposite sides or portions of such sides are made of conducting material. The box is packed with alternate layers of coarse charcoal powder, and of the pieces of soft iron, and is then connected to a source of electricity. According to the strength of the current and the time for which it is passed, iron of different degrees of hardness can be produced.—A. S.

XII.—FATTY OILS, FATS, WAXES, AND SOAP.

Heptadecylic Acid; Investigation of the Natural Occurrence of —. D. Holde. Ber., 1905, 38, 1247—1258.

Olive Oil.—In former communications (this J., 1901, 1903; 1902, 126) the author described a mixed glyceride isolated from olive oil and concluded that it contained a heptadecylic acid, $C_{17}H_{34}O_2$. He has now made a further examination of this substance, fractionally precipitating a larger quantity with magnesium acetate. After 15 precipitations a fraction consisting of nearly pure palmitic acid was obtained. The early precipitates contained acids of higher molecular weight (282—291) melting below $56^\circ C$., but after the 15 crystallisations a small amount of an acid, melting at 74° — $76^\circ C$., was separated. The second to the fifth fractions melting at 53.5° to $54.7^\circ C$., and having a mol. equiv. of 268 to 269, were united and further fractionated, and eventually yielded different acids, some of which had a mol. equiv. above 290. Hence the conclusion was arrived at that the supposed heptadecylic acid was really a mixture of acids of high molecular weight with palmitic acid. This was confirmed by the behaviour of an artificial mixture of 0.3 gm. of arachidic acid, 0.7 gm. of stearic acid, and 1 gm. of palmitic acid, which, when fractionated, yielded four successive fractions closely corresponding in mol. equiv. and m. pt. with the supposed heptadecylic acid. The solid fatty acids of the olive oil itself yielded, after 15 fractionations, an acid of mol. equiv. 368.7 and m. pt. 72° — $72.8^\circ C$. (lignoceric acid, $C_{24}H_{48}O_2$, has mol. equiv. 368 and m. pt. $80.5^\circ C$.).

Kreis and Hafner's Heptadecylic Acid.—The author has examined the actual substance prepared by Kreis and Hafner (this J., 1903, 1136), which had a m. pt. of 55.5° — $56.6^\circ C$., and, after numerous fractionations, has isolated stearic acid (m. pt. 68° — $69^\circ C$. and mol. equiv. 280.1).

Gérard's Heptadecylic Acid.—Gérard claimed to have isolated a heptadecylic acid from datura oil (this J., 1890,

1137), and the author's previous work (this J., 1902, 1459) supported that statement. By fractional distillation *in vacuo*, and repeated crystallisation of the products from alcohol, Gerard's "daturic" acid now yielded an acid with a m. pt. of 57°–58.5°, gradually rising to 63°–64° C., and with a mol. equiv. as high as 329.

Nördlinger's *Heptadecylic Acid* (this J., 1892, 445) was prepared by the author from palm oil, and submitted to further fractionation in larger quantities. In this case, too, the author concluded that when several fractions showed a constant m. pt. of about 56° C., and the mol. equiv. of heptadecylic acid, the phenomenon was due to an intimate admixture with palmitic acid or fatty acids of very high molecular weight. Eventually an acid was isolated melting at 68–68.5° C., and having the mol. equiv. 288.—C. A. M.

Lakes; Manufacture of Colouring Matter — J. Y. Johnson, London. From Badische Anilin und Soda Fabrik, Ludwigshafen-on-Rhine, Germany. Eng. Pat. 9861, April 29, 1904.

IN Fr. Pat. 342,903 of 1904 (this J., 1904, 989), is described the production of lakes from acid dyestuffs by the use of basic aluminium salts alone. Lakes possessing exactly similar properties are obtained by substituting for the

free hydrochloric, nitric or acetic acids, or their aluminium salts (*loc. cit.*), the barium or lead salts of one of acids, and carrying out the precipitation at a high temperature. For example, an insoluble yellow lake obtained by adding two parts of barium chloride to a mixture of 200 parts of a 4 per cent. paste of basic aluminium sulphate, and 1 part of Naphthol Yellow S, and b the mixture for some time. It is necessary that the amount of acid radical present in the lead (or barium) and aluminium salts should be only from one-sixth to one-twenty-fourth the amount required for the formation of the normal salts.—T. F. B.

Caoutchouc; Decomposition and Constitution of — C. Harries. Ber., 1905, 38, 1195–1203.

FURTHER experiments have shown that caoutchouc (this J., 1904, 830) when decomposed with water yields only levulinic aldehyde or acid. The compound melting at 197° C., which was obtained in small quantities and was previously described as an acid, is actually a superoxide of levulinic aldehyde. The decomposition of the ozone may be represented by the equation:—

fact that only levulinic aldehyde is formed by the position of caoutchouc ozonide with water, shows the caoutchouc hydrocarbon molecule, $C_{10}H_{16}$, must be of a closed carbon ring, and not, as has hitherto been held, of an open carbon chain. Molecular weight determinations with the pure caoutchouc ozonide point to formula $C_{10}H_{16}O_6$ for this compound, and it is probable that Para caoutchouc is a loose complex of methyleyclo-octadiene. (1.5) molecules :

formula is in accord with the properties of caoutchouc with its behaviour on destructive distillation.—A. S.

Solutions ; Novel or Improved Means of Preparing —, and the Utilisation of such Means and of subsequent Treatment for the Conversion of Waste into Serviceable Rubber. Robinson Bros., Ltd., and G. A. Clift, West Bromwich, Staffs. Eng. Pat. 6471, Feb 17, 1904.

The preparation of rubber solutions, and in the conversion of waste into serviceable rubber, the use of pyridine or other bases or "heavy bases," extracted from coal or other sources, is claimed. In the preparation of serviceable rubber from waste, the latter is first extracted with the pyridine or other bases, and the solution then treated with an acid, which combines with the bases, causes separation of the dissolved rubber. For the preparation of rubber solutions, the rubber is first dissolved with the pyridine or other bases, and the solution treated with an acid. The acid combines with the bases, and the rubber is retained in solution by the naphtha or other solvent.—A. S.

Artificial —. H. C. Bouet. Fr. Pat. 347,943, Nov. 18, 1904.

Parts of ceresin, 6 parts of lac or gum-lac, 13 parts of rosin, 3 parts of rosin and 6 parts of Trinidad asphalt are melted together, and 100 parts of waste gutta-percha, previously softened by treatment with boiling water, are added in small portions. Seventeen parts of calcium carbonate or calcined magnesia are then incorporated with the molten mass by kneading, until the mixture is homogeneous.—A. S.

Indic Press [Vulcanising] with a Horizontal Autoclave —. Soc. Morane, Jemie et Cie. Fr. Pat. 343,143, Nov. 21, 1904.

A CYLINDRICAL casing A, having doors at each end, is arranged to enclose the press-plates C of a series of hydraulic presses, the rams G, passing through the leather cup-joints H. In this way the material under treatment can be heated directly by steam introduced into the casing, this being of special advantage when vulcanising rubber materials under pressure. In treating extended bodies such as cables, the end doors are provided with circular openings, having suitable joints, through which the cable is led, and in this way a cable of any length can be treated.

—W. H. C.

XIV.—TANNING, LEATHER, GLUE, SIZE.

Tanning by Means of Hydrodynamic Pressure ; Comparison between —, and the Ordinary Method. H. de Manneffe. Collegium, 1905, 96, 100—105.

When the drum is employed as a mechanical adjunct in tanning, an indispensable condition is a swelling of the hide in order to promote a considerable separation of the fibres, so as to allow of a rapid absorption of the tanning infusion ; this separation tends to destroy the physical properties of the skin. Mechanical operations, after the hide has been impregnated with tanning material, bring about a purely artificial cohesion of the tannin easily destroyed however by water. Further disadvantages of this method are the impossibility of obtaining a leather perfectly tanned the length of time required, and the waste of mechanical power.

When the tannage is performed by hydrodynamic pressure, the maximum fixation of tannin can be obtained with a minimum amount of tanning material, the method can be employed independently of motive power, and the preparatory operations of liming, bating, &c., can be dispensed with. The acidity produced during the fermentation processes subsequent to the ordinary method of tanning, is indispensable in order to fix the tannin in the fibres. (See this J., 1905, 284.)—M. C. L.

Horny Matters, Process for the Treatment of —. L. E. Nottelle and L. A. Leroux. Fr. Pat. 347,702, Nov. 7, 1904.

HORNS, nail, fetlocks, wool, hair and other epidermal products are immersed in a mixture of nitric and sulphuric acids, and zinc chloride for 1 to 2 months, and after washing are transferred to a solution of tannin, alcohol and dextrin for 14 days; the operations being repeated, if necessary. The tannin may be replaced by potassium bichromate or alum. The amount of acid required varies between 20 and 50 gms. per litre, and the proportion of sulphuric acid to nitric acid from $\frac{1}{2}$ to $\frac{1}{3}$, according to the quality of the material and the degree of impregnation required. —M. C. L.

XV.—MANURES, Etc.

Sugar Cane; Influence of Sodium Salts on the Soil on the Composition of —. H. C. Prinsen-Geerligs. Mededeelingen van het Proefstation voor Suikerriet in West Java "Kagok" te Pekalongan, No. 76. Chem. Centr., 1905, 1, 897.

SUGAR-CANES take up but very little sodium even when grown on soil which has been treated with sodium chloride; the chief part of the chlorine present in the canes is combined with potassium. On treating the soil with sodium chloride, this reacts with the potassium salts present, and renders them available as plant-food. The fact that soil gives up only very small quantities of saline matter when extracted with pure water, but considerable amounts when extracted with sodium chloride solution is in accord with this view. An attempt to grow sugarcane on a soil as far as possible free from potassium, showed that the latter cannot be replaced by sodium, since notwithstanding repeated watering with sodium chloride solution, the plants soon died.—A. S.

Sugar Works; Use of Barium Aluminate in —. E. Rembert. Boll. Assoc. Chim. Sac. Dist., 1905, 22, 759-765. (This J., 1903, 563.)

FURTHER tests on the use of barium aluminat have confirmed the former results and show the purifying action of this product on diffusion juice, carbonated juice and first and second jet syrups. The increase in purity was over 1 per cent., due chiefly to elimination of organic non-sugar. Barium was present in all cases in the filtered juice and syrup. By the introduction each day of 18 litres of the reagent into the third and fourth pans of a quadruple effect of 1000 sq. metres, the period during which the apparatus could be run without cleaning was increased from 7 to 10 days, steam of lower pressure was required to produce evaporation, and the density of the issuing syrup was increased owing to the action of the reagent in preventing incrustation. Experiments show that used in considerable quantity, it does not act unfavourably on the metal of steam generators,

and that normally it does not cause any corrosion if the contact is prolonged, the corrosion due to the steam is minimised, or rendered nil, by the use of sufficient quantities of the reagent.—L. J. DE W.

Potato Starch; Conversion of — by Mineral Acid. Influence of Proportion of Acid, Steam Pressure, Time of Boiling on Formation of Dextrose and Dextrin. E. Parow. Z. Spiritusind., 1905, 28, 121-123.

THE author has studied the rapidity of conversion of potato starch by dilute sulphuric acid, as measured by the relative proportions of dextrose and dextrin in the extract, under varying conditions. Four experiments were made at concentrations which yielded syrups containing 30-31.5 per cent. of extract. The conditions employed in these conversions were:—(1) 0.8 per cent. of sulphuric acid (on the raw material), boiled under a pressure of 14.5 lb per sq. in.; (2) 0.8 per cent. of acid, boiled under a pressure of 22 lb.; (3) 0.8 per cent. of acid, boiled under a pressure of 29 lb.; (4) 1.0 per cent. of acid, boiled under a pressure of 14.5 lb.

Samples of the syrups were withdrawn at intervals and examined as to the progress of conversion. The following numbers, selected from the tables and accompanying the paper, illustrate the nature of the results; the times are recorded from the moment the full pressure chosen for the experiment was reached.

Conversion No.	Dextrose, Per Cent. of Total Extract		
	(1)	(2)	(3)
After 10 minutes under full pressure	16.02	27.17	50.2
20 "	31.06	45.5	62.5
30 "	42.5	57.7	75.16
40 "	54.3	—	—
60 "	68.7	—	—
80 "	83.3	—	—

Although the use of higher pressures enormously increases the velocity of the conversion, it is preferable practice to boil with moderate pressure for a longer time in order to expel the volatile aroma characteristic of potato starch.—J. F. B.

II.—BREWING, WINES, SPIRITS, Etc.

ys; Defects of the Present Season's ——. Vogel.
Z. ges. Brauw., 1905, 28, 205—209.

Nerous complaints have been made by Bavarian
ors concerning the abnormal behaviour of the malts
red from barleys of the 1904 crop. The yield of extract
htly lower than in the previous season. The wort does
arify as it should; in some cases it is the main wort
runs off slowly and in other cases it is the spargings
are faulty. The majority of the complaints refer
attenuations, which are frequently 10 per cent. or
in excess of the usual values. In conjunction with this
it is stated that the beer does not drop bright in
ermenting tuns, the yeast shows no tendency to
k," and so long as it remains in suspension, it con-
s to work; it settles well, however, in the lager

With regard to the clarification of the wort, the
r states that as long as the weather remains cold,
difficulty may be cured by allowing the mixture of
and water to remain for a few hours before
ng, but in hot weather such a procedure is likely to
rm. As regards the excessive attenuations, attention
d first be paid to the malt, and a remedy might be
by curing at a higher temperature, or else main-
ing the present curing temperature for a somewhat
e time. The difficulty might also be surmounted
fermentation tun by slightly chilling the beer when
ves at the stage of full fermentation ("early head").
is ease it would be well to pitch at a slightly higher
erature, in order that fermentation may set in early
tongly, and as soon as the beer reaches the stage of
ly head," at a temperature, say, of 10° C., to start
temperatur so that the temperature is lowered
2° C. as quickly as possible. Should the above means
a curtailing the attenuations, the author proposes
ange the procedure during mashing by introducing,
all precautions, a modification of the principle of
spring" mashing process when making the decoe-

This consists in dropping the cooler mash into
hot water or boiling mash, so that the temperature
"stand" for saccharification is reached from above
d of from below, and the temperatures, at which
a proportion of readily fermentable sugar is produced,
voided.—J. F. B.

ermentation; Contribution to the Study of ——. Kayser.
Ann. de la Brass., 1905, 8, 5—7.

author's experiments go to show that the lactic
nt produces mannitol and afterwards consumes the
; the attack being, however, retarded by the presence
cohol.—C. S.

m Dioxide; Fixation of —— by Amphoteric Amino
ics. M. Siegfried. Z. physiol. Chem., 44; through
eb. f. Brau., 1905, 22, 179—180.

author finds that solutions of the salts of the amino

acids of the glycecol series, including those of asparagine,
aspartic acid and glutamic acid, possess the property of
absorbing carbon dioxide to form the salts of the corre-
sponding carbanic acids, e.g., in the case of glycecol
 $\text{COOH.CH}_2\text{.NH}_2\text{COOH}$. Solutions of the salts of the
amino acids have a strong alkaline reaction, and
the passage of a current of carbon dioxide through
a solution of a barium or calcium salt of this
series does not cause an immediate precipitation of
earthly carbonate. The author has isolated and charac-
terised a series of calcium salts of these carbanic acids.
They are soluble in water, but are slowly decomposed on
long standing, or rapidly on heating, with precipitation
of the carbonate. A similar loose fixation of carbon
dioxide in presence of a base was observed with other
amphoteric amino bodies, including peptones, albumoses
and true albumin, and the nature of the reaction is
probably the same as in the formation of the carbanic
acid salts.

There is evidence also that the free amino acids and the
albuminoid derivatives possess a certain affinity towards
carbon dioxide even in absence of a base, although the
combination so obtained is far less stable. A solution
of asparagine absorbs considerably more carbon dioxide
than does water, owing probably to the formation of a
carbanic acid; solutions of peptones, albumoses, &c.,
behave in a similar manner. It is suggested that the
nitrogenous constituents of beer play an important part
in fixing the carbon dioxide at low temperatures in the
manner indicated above, and that carbanic acids are
produced which are decomposed, at the higher tempera-
ture of the palate, with regeneration of carbon dioxide.

—J. F. B.

Berr; Carbonated ——. A. E. Berry. J. Inst. Brewing,
1905, 11, 153—174.

THE time and stage at which the beer is carbonated
have a great influence on the results; with simple carbona-
tion the best beers are obtained when the process is per-
formed after about two months' storage. The correct
proportion of carbon dioxide for obtaining a good condition
is about 0.4 per cent. of the weight of the beer, but the
pressure to be employed in carbonating depends largely on
the character and gravity of the beer. The brewing of
light gravity ales for carbonating requires careful attention.
As a rule, English malt alone is not suitable for light bottled
beer on account of its high proportion of protein. A
small proportion of flaked maize is frequently advan-
tageous. The duration of boiling the wort is also an
important factor; it should be long enough to ensure
complete coagulation, but not so long as to cause the
re-solution of precipitated albuminoids. The best
coagulation in this class of wort is obtained when the
hops are added in two portions, part being reserved until
the wort has been boiled for some time. The yeast should
be carefully cultivated and strengthened, because, except
when chilling and filtration are resorted to, the whole of
the work of cleansing the beer from unstable albuminoids
falls on the yeast. Some beers do not carbonate so well
after they have been filtered, but in the case of chilled
beers filtration is imperative. It is advisable to store the
beer in cask for two to three weeks before chilling, since
it will remain clear for a longer time in bottle; if this be
done, the filtration should be effected in the cold cellar
and not at a higher temperature.—J. F. B.

Wort; Treatment [Boiling] of ——. F. B. Aspinall and
M. J. Cannon, both of London. Eng. Pat. 10,361,
May 5, 1904.

THE wort is brought into contact with highly-heated
surfaces and retained in contact therewith at a regulated
pressure as long as desired. For this purpose the wort is
forced by a pump through a check valve into a serpentine
pipe heated by a steam-jacket. From this pipe the wort
passes into a cooler, consisting of a similar pipe to the
heater, but having a cold-water jacket. The end of the
pipe as it leaves the cooling jacket is closed by a valve
which can be regulated to open at any desired pressure.

The pressure of the steam supply is also regulated to give the required heat.—W. P. S.

Evaporator for Evaporating the Liquid in Breweries, Wash, Sewage Waste or Spent Dyes and the like, and Concentrating the Solids in the same, the Evaporator being also Applicable as a Smoke Washer. A. B. Lennox. Eng. Pat. 9516, April 26, 1904. XVIII. B., page 453.

Meat; New Process of Preserving —. J. Craveri, Buenos Ayres. Eng. Pat. 13,266, June 11, 1904.

THE preserving liquid employed consists of a mixture of 100 litres of a saturated solution of sodium chloride and three to five litres of glacial acetic acid. To this, a small quantity

of potassium nitrate may be added. The liquid may be prepared by saturating dilute acetic acid with sodium chloride. The meat may be preserved in pieces, or preserving liquid may be injected into an artery of a freshly killed and bled animal.—W. P. S.

UNITED STATES PATENT.

Milk; Evaporated. L. P. Britt, New York, Assignor to F. Mayer, New York. U.S. Pat. 783,015, Feb. 21, 1905.

WHOLE or skimmed milk is evaporated under reduced pressure at a temperature below 105° F.; while this is in the evaporating pan, a current of electricity (three volts) is passed through it. The milk is then reduced to a pasty mass, or completely dried and ground. The product is soluble in water, and is apparently sweeter in taste than ordinary milk.—W. P. S.

FRENCH PATENTS.

Milk; Process for Making Dry Soluble —. A. C. Jung. Fr. Pat. 347,739, Nov. 8, 1904. Under Internat. Conv., May 17, 1904.

THE process consists in preparing a dry, but easily soluble milk by adding calcium in the form of a compound of higher alcohol, preferably a calcium compound of a higher alcohol (e.g., calcium sacrate), previous to evaporation. It is claimed that the reason why ordinary dried milk is so difficult to dissolve, is due to the concentration of the lactic acid, naturally present, during the evaporation. Concentrated lactic acid tends to separation of the milk in an insoluble form. The addition of a known quantity of calcium sacrate neutralises the lactic acid, and renders soluble the calcium salts which would otherwise be made insoluble by the boiling.—M. C. L.

Milk Powders and Products; Process for Preparing —. C. Jung. Fr. Pat. 347,877, Nov. 12, 1904.

EQUAL quantities of milk, either whole or skimmed, are each separately boiled and then evaporated under reduced pressure, to thick syrups. These are now mixed and further evaporated to dryness and powdered. Extracts of coffee, tea, cocoa, barley, &c., may be added before evaporation.—W. P. S.

Filter Beds for Sewage. M. J. Adams, Scotswood, Tyne. Eng. Pat. 8944, April 19, 1904.

CERTAIN transverse divisions or barriers are so placed in the filter-bed, that the filtering material is not washed away by the supply of sewage. A tipping bucket or trough is employed to give an intermittent supply to the bed.—W. P. S.

ator for Evaporating the Liquid in Brewers' Wash, Waste or Spent Dyes and the like, and Concentrating the Solids in the same, the Evaporator being also suitable as a Smoke Washer — A. B. Lennox, Castle-on-Tyne. Eng. Pat. 9516, April 26, 1904.

apparatus consists of a cylindrical casing A, having a lower portion and a removable bottom discharge, and is divided into two compartments C and D by partition B. It is provided with a cover plate G, and a pipe F, connected to an exhaustor or vacuum. Through the cover G, a slightly tapered tube H leaving an annular space E between the tube H and partition B. The tube H has an inlet branch J, and a rod L, which passes through a stuffing box in the closed top of the tube, and is connected at its lower end to a perforated bucket M. The upper part of rod L has a thread cut upon it and passes through a stuffing box so that by rotating the rod L the bucket M may be raised or lowered, exposing more or less of the perforated bucket and so regulating the admission of gas into the liquid to be evaporated or to be used for washing. Waste is fed through the opening O, and hot gas or steam is drawn by the exhaust through the pipe J, passes through the perforations in the bucket M, up through the tube H and escapes, laden with vapour, or in the case of washing, free from solid matter, out through the tube to the exhaustor. The solids deposited may be drawn through the bottom opening closed by the plate P. —W. H. C.

and the like; Purification of — H. Peschges, Perbern, Germany. Eng. Pat. 10,867, May 11, 1904.

When tank is completely filled with water, the displaced air is drawn through a tube at the top. The air-pipe and the supply pipe are then closed, and the sewage supply

pipe, which enters near the bottom of the tank, is opened, as is also the discharge pipe, which enters at the bottom of the tank and reaches nearly to the top. The upper end of the discharge pipe is funnel-shaped. The sewage is drawn from a well, and the discharge pipe delivers the water into a second well. The sludge which settles in the tank is drawn off by means of a pipe at the funnel-shaped bottom of the tank, whilst oily matters collecting at the top of the tank pass through a small tube into a separate collecting well. The action of the plant is that of a siphon. —W. P. S.

Slag; Treating Blast-Furnace —, and Utilising the Products thereof. J. H. W. Stringfellow. Eng. Pat. 5648, March 8, 1904. X., page 445.

FRENCH PATENT.

Sewage and Foul Waters containing Organic and Albuminoid Matters; Product named "Phospho-zinc-alumino-magnesian," applicable to the Treatment of —, and Process of Manufacturing the same. J. M. Lallemand and A. Goutierre. Third Addition, dated Jan. 22, 1904, to Fr. Pat. 323,900, Aug. 14, 1902 (this J., 1903, 568; 1904, 556, 1040).

Two hundred kilos. of natural aluminium phosphate are calcined, ground, and treated with 100 kilos. of hydrochloric acid of "20°–22°," or 100 kilos. of sulphuric acid of "53°," and 300 kilos. of water. The product obtained is used as a precipitant for sewage and effluents, and it is claimed that the sludge produced forms a valuable manure. —A. S.

(C).—DISINFECTANTS.

Smoke; Antiseptic Properties of certain kinds of —. A. Trillat. Comptes rend., 1905, 140, 797–799.

SAMPLES of soot taken from chimneys of houses and factories were all found to contain paraldehyde to the amount of 0.28 to 0.35 per cent. (compare this J., 1904, 744 and 1164). This explains the presence of formaldehyde in the atmosphere, already noted by Henriot (this J., 1904, 209 and 758). It is found that the combustion of sugar, saccharine substances and certain resins gives rise to formaldehyde, especially if the combustion is carried out in an iron vessel. The products of combustion of sugar are also found to include acetone, methyl and ethyl alcohols, acetic acid, benzaldehyde, and certain phenolic compounds. It is considered that the acetone and acetic acid would prevent the polymerisation of the formaldehyde, which would account for the powerful germicidal properties of the products of combustion of sugar; e.g., it was found that *B. coli*, *E. subtilis*, and the bacteria of typhoid and cholera were destroyed by a treatment for four hours at 40° C. in a 12 litre vessel into which the products of combustion of 2 grms. of sugar were introduced. —T. F. B.

ENGLISH PATENT.

Wood and Goods of Different kinds, and for Drying such Goods; Impts. in Heating, Steaming and Chemically Treating —. C. McWhirter. Eng. Pat. 14,869, July 2, 1904. IX., page 443.

XIX.—PAPER, PASTEBOARD, Etc.

Wood Pulps; Percentage of Resin in Chemical —. W. Herzberg. Mitt. K. Materialprüfungsamt, 1904, 22, 180–182.

THE author has determined the percentage of resin in a large number of samples of wood-cellulose of good quality. The air-dry cellulose was extracted with ether in a Soxhlet's apparatus; the results are summarised in the following table:—

Description of Pulp.	Number of Samples Analysed.	Percentage of Resin.		
		Maximum.	Minimum.	Mean
Sulphite pulps, Mitscherlich:				
Unbleached	19	0.85	0.37	0.58
Bleached	6	0.60	0.32	0.44
Sulphite pulps, Ritter-Kellner:				
Unbleached	11	0.78	0.43	0.59
Bleached	7	0.65	0.22	0.45
Sulphite pulps, process unknown:				
Unbleached	8	1.07	0.38	0.72
Bleached	6	0.60	0.28	0.43
Soda and "sulphate" pulps:				
Unbleached	6	0.13	0.01	0.04
Bleached	6	0.07	0.01	0.03

Hence it is concluded that in the case of sulphite pulps the method of boiling has no appreciable influence on the percentage of resin, that bleached pulps contain slightly less resin than unbleached, and that the average proportion of resin in a sulphite pulp of superior quality is about 0.5 per cent. Soda and "sulphate" pulps contain on the average only 0.04 per cent. of resin, and the difference between these and the sulphite pulps is so marked that the proportion of resin might serve as a means of distinguishing between the two classes of pulp.—J. F. B.

Textile Fabrics, Paper or other Lamellar Materials; Engraved Bools or Rollers for Producing an Improved Reflecting Finish on —. W. J. Pope and J. Häbner. Eng. Pat. 7745, April 2, 1904. V., page 437.

FRENCH PATENTS.

Paper Pulp for the Manufacture of Photographic or other Papers; Process for Eliminating the Metallic Particles contained in —. M. le Normant des Varannes and A. Regnouf de Vains. Fr. Pat. 347,925, Jan. 22, 1904.

THE invention relates to the production of a paper free from all metallic particles, and especially suitable for photographic purposes. The heavier metallic particles are first removed from the pulp which is then freed from a considerable portion of its water by passing it over suction boxes, and then pressing it. The pulp thus produced is rolled, and treated with gaseous chlorine in air-tight receptacles; this treatment, which converts the metals into chlorides and bleaches the pulp at the same time, is complete in an hour. The pulp is then thoroughly washed in a stone washer, sized, and then made up in the usual manner, with the exception that, in order to prevent the introduction of fresh metallic particles, the various parts of the paper machine with which the paper comes in contact are covered with chlorite.—T. F. B.

Cellulose; Process for the Acetylation of —. Badische Anilin und Soda Fabrik. Fr. Pat. 347,906, Nov. 14, 1904. Under Internat. Conv., Oct. 1, 1904.

THE processes at present in use for the preparation of acetylcellulose have the disadvantage that the acetylcellulose is dissolved in the acetic acid or anhydride, and must be subsequently precipitated. In the present process the solution of the acetylcellulose is prevented by carrying out the reaction in presence of a sufficient quantity of some liquid in which acetylcellulose is insoluble (e.g., ether or benzene). The acetylation proceeds more rapidly if the cellulose (cotton, mercerised or not, wood, paper, &c.) is first damped; it may be impregnated with dilute sulphuric acid to obviate the necessity of introducing the latter into the solution. The sulphuric acid may be replaced by organic sulphonic acids, or by phosphoric acid. One of the advantages of this process is that it enables cotton in the form of flock, yarn, or fabrics to be acetylated without altering its appearance. The following is an example of the process: 10 kilos. of dry degreased cotton are heated in a mixture of 50 kilos. of acetic anhydride containing 5 per cent. of sulphuric acid, and 150 kilos. of toluene, at a temperature of 70°–80° C., wrung out, washed and dried.—T. F. B.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES, AND EXTRACTS.

Thorium and the Cerite Earths; Separation of — from Normal Sodium Sulphite. H. Grossmann. M.H., page 453.

Mercury Oxyhalides; New —. T. Fischer and J. v. Wartenburg. Chem.-Zeit., 1905, 29, 308.

MERCURIC oxide only combines on heating with mercuric halides to form basic salts, when the temperature conditions are very carefully regulated. Thus, the oxyhalides HgO , HgCl , and oxybromide HgO , HgBr are formed by heating the materials together with a little water at 100° C. in sealed tubes.

These compounds are both dark red crystalline compounds, which can be separated from the sludge by decanting and running water. On treatment with hydrochloric acid, mercurous and mercuric halides are obtained quantitatively, a reaction by which these basic salts can be analysed. To prepare mercurous oxyiodide $\text{HgI}_2 \cdot 3\text{HgO}$, alcoholic potassium is added drop by drop to a boiling solution of mercuric iodide. The resulting mercurous iodide is filtered in sealed tubes with mercuric oxide for 80 hours at 100° C., when crystals are obtained as above.—B. J. S.

Carbon Tetrabromide; Preparation and Purification of —. A. von Bartal. Chem.-Zeit., 1905, 29, 378.

ACCORDING to Wallach, carbon tetrabromide is formed by treating acetone with bromine in extremely dilute alkaline solution. In order to increase the yield of tetrabromide, the following modification is suggested. 150 c.c. of solution containing 25 per cent. of sodium hydroxide are added to one litre of water and treated with 1 c.c. of acetic acid and 5 c.c. of bromine. The mixture is thoroughly shaken, allowed to rest for two or three hours and the precipitate filtered off. The filtrate is then treated repeatedly with fresh acetone and bromine until no further precipitation takes place. The best result is obtained with a solution of 6 c.c. of acetone and 20 c.c. of bromine. The modification is best effected by dissolving the product in a quantity of boiling methyl alcohol, filtering while still hot, allowing the tetrabromide to crystallise, and adding water in excess to complete the separation.—D. B.

P. line Mercuriodides. M. François. Comptes rend., 1905, 140, 861—863.

Compound $(C_5H_5N.HI)_2.HgI_2$ is obtained as colourless crystals melting at $159^\circ C.$ by warming on the water-bath of pyridine, 20 c.c. of hydrochloric acid and 100 c.c. of potassium-mercuric iodide solution (100 grms. mercuric iodide and 75 grms. of potassium iodide per

Compound $C_5H_5N.HI.HgI_2$ is best obtained by warming on the water-bath 2.27 grms. of mercuric iodide, 10 grms. of pyridine hydroiodide, and 10 c.c. of water in a conical flask. After the reaction is complete, 10 c.c. of water are added, and the mixture is warmed for 10 minutes. The product is then allowed to crystallise; pure, it melts at $151^\circ C.$

Compound $(C_5H_5N.HI)_2(HgI_2)_3$. 9 grms. of pyridine iodide, 18 grms. of mercuric iodide, and 250 grms. of water are warmed at $90^\circ C.$ for two hours. The mixture is cooled to $60^\circ C.$, filtered, and the filtrate again cooled to 10° , when crystals are obtained, melting at $104^\circ C.$

Compound $C_5H_5N.HI(HgI_2)_2$. 60 grms. of mercuric iodide are dissolved in 90 c.c. of 30 per cent. hydroiodic acid. The mixture is diluted with 600 c.c. of water, and 10 c.c. of 1 per cent. aqueous pyridine is run in. A precipitate is obtained, which on recrystallisation furnishes compound melting at $121^\circ C.$ —B. J. S.

Menthone derived from Hexahydrothymol. L. Brunel. Comptes rend., 1905, 140, 792—794.

Two stereo-isomeric hexahydrothymols, or thymenols (see this J., 1905, 248) are converted, on action with the calculated quantity of chromic acid in acetic acid solution, at low temperatures, into thymenone, $C_{10}H_{16}O$. This is a colourless liquid, of similar taste and odour to natural menthone; its sp. gr. at $0^\circ C.$ is 0.911, and its b. pt. $212^\circ C.$ It is slightly soluble in water, and soluble in alcohol, ether and acetic acid. On action it gives rise to β -thymomenthol. It does not combine with alkali bisulphites. Thymomenthylamine, $C_{10}H_{17}NH_2$ is produced by reduction of the oxime; it is a colourless liquid, b. pt. $208^\circ C.$, rapidly oxidised by air; it forms salts with acids, including a crystalline nitrate.—T. F. B.

Carvones and Essential Oils. 71st Communication. Carvone and its Reduction Products; Constitution —. O. Wallach and H. Köhler. Annalen, 1905, 349, 94—116.

BAEYER's formula for eucaryone,

is in accord with several properties of the compound, the authors bring forward evidence in favour of the view that the ketone is trimethyl (1.4.4) -cycloheptanone- $(\Delta^{5,7})$ -one-(2),

Compound would, with regard to its optical properties, behave as an alcohol

the formation of eucaryone from carvone hydrobromide, is probable that a compound corresponding to von Beyer's formula is formed as an intermediate product. (See also this J., 1899, 397.)—A. S.

Urbanum; Origin and Composition of Essential Oil of —. Glucoside and New Enzyme. E. Bourquelot and H. Hérissay. Comptes rend., 1905, 140, 870—872.

Root of *geum urbanum* contains a glucoside (called by the authors *geine*), which is decomposed by the accompanying enzyme (*gease*). On treating the purified oil with benzoyl chloride, benzoyl-eugenol was obtained. It was not found possible to decompose the glucoside by means of known

enzymes (emulsin, invertin, &c.). Hence, it is concluded that *gease* is a new enzyme. Attempts were made to isolate the glucoside by dissolving the extract in alcohol and pouring an equal volume of ether on to the surface of the solution without mixing the liquids. On standing, spherical crystals, which gave the reactions of *geine*, were deposited on the walls of the vessel. B. J. S.

[m-Tolylsemicarbazide] Pharmaceutical Compound; Manufacture of a —. H. E. Newton, London. From Farbenfabr. vorm. F. Bayer and Co., Elberfeld, Germany. Eng. Pat. 12,440, June 1, 1904.

THE nitrile of *m*-tolylhydrazine-carboxylic acid, $CH_3.C_6H_4.NH.NH.CN$, obtained by the action of cyanogen bromide on *m*-tolylhydrazine, is converted into *m*-tolylsemicarbazide by the addition of 1 mol. of water. The nitrile may be dissolved in ether, and the solution shaken with several portions of dilute hydrochloric acid; the semicarbazide is obtained on evaporating the hydrochloric acid extracts. (See Eng. Pat. 7954 of 1904; this J., 1905, 345.)—T. F. B.

UNITED STATES PATENTS.

Methyl Chloride; Apparatus for Making —. M. E. Donane, Paris. U.S. Pat. 777,406, Dec. 13, 1904.

Two iron vessels, lead lined, 1 and 2, are bolted together to form an autoclave, in which the hydrochloric acid

and methyl alcohol are heated. A tube 9 extends upwards from the autoclave, and is closed by a plate 10, which carries a pressure-gauge and safety-valve. The tube 14 serves for the introduction of the acid and alcohol, and also for the removal of the methyl chloride. The autoclave is contained in a vessel 15, which can be heated by hot water, introduced through the cock 16. Hot water may also be transferred from this vessel into the space within the autoclave 20, by the pipe 19. This space is provided also with another water inlet 21, and an outlet 22. The methyl chloride is run off through the pipe 21 to a receiver, whence it is passed through a vessel containing milk of lime, and then to another receiver; thence it passes through two vessels containing sulphuric acid, and lastly up a column of coke impregnated with sulphuric acid. It is then ready for condensation and compression. The six vessels (receivers and washers) are all placed in a suitable casing, and "connected together to form a battery."—T. F. B.

Dialkyl Carbinols [from Cyclo-octyridene-acetic Acid]; Process of Making — F. Hoffmann, Elberfeld, Germany, Assignor to Farbenfabr. of Elberfeld Co., New York. U.S. Pat., 778,243, Dec. 27, 1904.

The dialkylcarbinols derived from cyclo-octyridene-acetic acid, of the composition $C_8H_{15}.CH:CH.CR_2OH$ are obtained by the interaction of cyclo-octyridene-acetic acid with the addition compounds of an ether and the corresponding alkyl magnesium halide. The reaction product is decomposed with water, and the ethereal solution is shaken with sodium carbonate solution and distilled with steam; the resulting ethereal solution, which contains the carbinol, is dried, and distilled *in vacuo*. The application of the above process to the preparation of the known dimethylcarbinol

is especially claimed.—T. F. B.

FRENCH PATENT.

Oléo-Resin Derived from the Peel of Citrus Fruits, and Process of Manufacturing it. E. J. Sheenan, Fr. Pat. 348,444, Nov. 11, 1904.

SEE U.S. Pats. 775,502 and 775,546 of 1904; this J., 1904, 1237.—T. F. B.

GERMAN PATENTS.

Dihydroxy-Aldehydes; Process for the Preparation of Aromatic — R. Sommer, Ger. Pat. 155,751, Aug. 21, 1902.

AROMATIC dihydroxyaldehydes, in which the hydroxyl groups occupy the α -position with respect to each other, are obtained by oxidising monohydroxyaldehydes with hydrogen peroxide in presence of iron salts. For example 1 kilo. of ferrous sulphate dissolved in 30 litres of water, and 115 kilos. of a 3 per cent. hydrogen peroxide solution are added to a solution of 12.2 kilos. of *p*-hydroxybenzaldehyde in cold water. The mixture is heated to 50° C. for an hour, and the iron is precipitated by barium hydroxide. The proto-catechuic aldehyde may then be precipitated from the filtrate by means of lead acetate. Proto-catechuic aldehyde is also obtained by this method from *m*-hydroxybenzaldehyde, whilst salicylic aldehyde furnishes *o*-oxylaldehyde (2,3 dihydroxybenzaldehyde).—T. F. B.

2-Alkyl-oxypyrimidines; Process for Preparing — Farbenfabr. vorm. F. Bayer und Co. Ger. Pat. 155,752, March 14, 1903.

2-ALKYLOXY-6-IMINO-6-OXYPYRIMIDINES are prepared by the interaction of alkyl-ethers of iso-uric, $NH.COOR.NH_2$, with cyano-acetic esters in which the hydrogen atoms in the methylene group are replaced by a metal. These compounds may be converted into xanthine by reducing their nitroso-derivatives to alkylloxypoxanthines, and heating these with formic acid.—T. F. B.

Thiopyrimidine Derivatives; Process for Preparing — Farbenfabr. vorm. F. Bayer und Co. Ger. Pat. 155,753, March 14, 1903.

IMINOTHIOPYRIMIDINES of the constitution

where R represents hydrogen or alkyl, are produced by the action of metal-substituted cyano-acetic esters, $CN.CM_2.COOR$, on thiourea or its mono-alkyl derivatives. These derivatives can be converted, by the process described in the preceding abstract, into the corresponding thiuhypoxanthine or its alkyl derivative, which is converted on oxidation to xanthine or alkyl-xanthine.—T. F.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Gelatinobromide Films; Action of Hydrogen Peroxide on — W. Morekens. Z. angew. Chem., 1904, 489—490.

THE author concludes that the action of hydrogen peroxide upon gelatinobromide films is not of a "photo-active," but of a chemical character, as Russell has maintained, and that the real agent in producing an immanent oxygen arising from the decomposition of hydrogen peroxide in the film. The effect of ozone is probably due to a similar cause. Repetition of Russell's experiments with various metals leads to the conclusion that the capability of metals to form hydrogen peroxide in air is probably connected directly with their electro-positive character.—J. T. D.

Actino-autography. G. Lamm. Chem.-Zeit., 1905, 305—306.

WHEN photographic plates, on the films of which deposited small objects of copper and brass, are exposed in the dark, film upwards, in boxes made of straw board for two or three days, they are found to be covered on, and shadows of the articles may subsequently be obtained by developing. This is due to the radio-activity of the cardboard.

The light emitted seems to proceed, not from the surface as a whole, but from a number of points and hence it gives rise to multiple and irregular outlines. After an experiment has been made the box becomes "fatigued," but recovers itself on being allowed to stand. Other substances, notably, aluminium, possess the property of radio-activity, and photographers are therefore warned against using dark slides of this metal.—B. S.

UNITED STATES PATENT.

Photographic Emulsion; Colour-Sensitive — and Process of Making same. K. Kieser, Elberfeld, Germany, Assignor to Farbenfabr. of Elberfeld New York. U.S. Pat. 785,219, March 21, 1905.

SEE Fr. Pat. 336,298 of 1903; this J., 1904, 337.—T. B.

FRENCH PATENT.

Paper Pulp for the Manufacture of Photographic or other Papers; Process for Eliminating the Metallic Particles contained in — M. Le Normant des Varannes and A. Regnouf de Vains. Fr. Pat. 347,925, Jan. 22, 1904. XIX., page 451.

XXII.—EXPLOSIVES, MATCHES, Etc.

ENGLISH PATENTS.

Explosives; Manufacture of — N. Ceipek, Vienna. Eng. Pat., 14,480, June 27, 1904.

CLAIM is made for a mixture of ammonium nitrate, anhydrous nitrate and aluminium powder. Specified proportions of these ingredients are:—10 to 15 parts of ammonium nitrate with 90 to 85 parts of a mixture of 85 parts of ammonium nitrate with 15 parts of aniline nitrate.—C. A. M.

Combustive Compound; Manufacture of an Improved
— H. Maximi, Brooklyn, N.Y. Eng. Pat. 28,376,
27, 1904.

aking rods or cylinders of a self-combustible com-
d, designated "motorite," which are intended to be
d in a confined space to provide motive power for
g automobile torpedoes, the difficulty presents
that if the rods are made by forcing the plastic
orite" through dies, longitudinal rifts or cracks
which allow the flame to pass along the rod, so that
ive rather than progressive combustion ensues.
oid this difficulty the "motorite," which is a mixture
parts of nitroglycerin, 5 parts of soluble guncotton,
arts of trinitrocellulose or "military guncotton"
dissolved in 30 parts of any suitable solvent
as acetone, is kneaded thoroughly and rolled
sheets, part of the solvent being evaporated by
g the rolls to 120° F., any cracks that may be
d being in a direction parallel to the surface of the
. The sheets are punched into discs, which are
d one upon the other and pressed forming short
ers. The flat surfaces of these cylinders are
ned with the solvent, several cylinders being then
up into rods or longer cylinders. The solvent is
off and the sides of the rods coated with a varnish
is not self-combustible and which is composed of
ion guncotton, gum camphor and a suitable solvent,
ably acetone. The cylinders are then dried and
into metal cases. In rods so formed any cracks
a direction at an angle with the length of the rod,
nsequently the rods burn slowly and steadily.

outlet-channels for the acid are provided with over-
abes.—A. S.

Matches; Preparation of an Ignition Material for
Free from Phosphorus. R. Gans. Ger. Pat. 157,124,
Jan. 14, 1903.

The patentee claims the employment as a constituent of
ignition masses for matches of the sulpho compounds
obtained by the action of sulphur on a salt or salts of a
polythionic acid (di-, tri-, tetra- and pentathionic acid)
or on salts of acids obtained by the oxidation of poly-
thionic acids or thiosulphuric acid. The following
example is given of the composition of a useful ignition
mass:—The sulpho compound of cuprous-barium poly-
thionate, 20; punice, powdered quartz, &c., 27.2; potas-
sium chlorate, 44.8; and glue, 8 per cent. (See also this
J., 1902, 792.)—A. S.

XXIII.—ANALYTICAL CHEMISTRY.

APPARATUS, Etc.

Quartz Glass; Use of — in Chemistry. M. Berthelot.
Comptes rend., 1905, 140, 817—820.

QUARTZ glass has proved very useful to the author in the
study of reactions at very high temperatures. It can
readily be worked in the oxyhydrogen, or preferably, in
the oxy-acetylene flame; and uniform tubes are obtainable
of 10 mm. diameter, and 0.7 mm. thickness, which will
stand a pressure of 3 atmospheres up to the softening
point, viz., 1400° C. Tubes 20—25 mm. in diameter were
also made, but they were not sufficiently uniform in thick-
ness to be used for pressure.

Quartz glass sealed tubes are conveniently heated in
electrical resistance furnaces, and can be cooled after-
wards by plunging into cold water, whilst at a red heat.
They are not attacked by acids.—B. J. S.

Quartz Glass; Permeability of —. M. Berthelot.
Comptes rend., 1905, 140, 821—825.

At high temperatures quartz glass allows gases to pass
through its walls by a process of osmosis. Thus, a tube
containing 4 c.c. of oxygen was heated at 1300° C. for
an hour, and after cooling, was opened under mercury;
3 c.c. of nitrogen were then found to have diffused
through from the air. The hydrocarbons, naphthalene
and methane were also heated in a similar way. At the
end of an hour carbon, together with a very small quantity
of hydrogen and nitrogen was found in the tube, showing
that at high temperatures these compounds are resolved
into their elements.—B. J. S.

Quartz Vessels; Use of — in the Laboratory. F. Mylius
and A. Meusser. Z. anorg. Chem., 1905, 44, 221—224.

WATER has no appreciable action on vitrified quartz, even
at 100° C. Alkaline solutions form soluble silicates with
the quartz, the action beginning at comparatively low
temperatures. The following are some of the results
obtained with a quartz flask of 78 c.c. capacity, the surface
in contact with the liquid being in each case 89 sq. cm. :—

Reagent.	Duration of test.	Temperature.	Loss of weight.
		°C.	Mgrms.
Water	several days	18—100	0.0
10 per cent. solution of ammonia	2 days	18	0.8
10 per cent. solution of sodium hydroxide	2 days	18	0.4
30 per cent. solution of potassium hydroxide	4 days	18	1.2
30 per cent. solution of sodium hydroxide	2 days	18	0.0*
2N-sodium hydroxide solution	3 hours	100	48.4
2N-sodium carbonate solution	3 hours	100	12.4
2N-potassium hydroxide solution	3 hours	100	31.0
N ₄ -sodium hydroxide solution	14 days	18	2.0
N ₄ -sodium carbonate solution	14 days	18	0.6
Saturated solution of barium hydroxide	14 days	18	0.0*
Saturated solution of sodium phosphate	14 days	18	0.0*
N ₄ phosphoric acid solution	14 days	18	0.0*
25 per cent. solution of ammonia	60 days	18	0.0
25 per cent. solution of ammonia	6 hours (with four renewals of the reagent)	up to 60	2.6

* In these experiments a slight loss of weight would have been shown by a more sensitive balance.

When barium hydroxide solution was kept in a quartz vessel for six months at 18° C., with exclusion of air, small prismatic crystals of barium silicate formed on the sides of the vessel. Dilute acids, with the exception of hydrofluoric acid, have no appreciable action on quartz vessels, even at 100° C.; concentrated sulphuric acid is also without action. Phosphoric acid has no action at 18° C., but when concentrated in a quartz vessel, a reaction begins above 400° C., which causes strong corrosion of the vessel, and separation of white silicic phosphate. Hydrofluoric acid acts strongly upon quartz vessels. From a 30 per cent. solution of potassium hydroxide, quartz vessels absorb potash; the alkali cannot be removed by rinsing with cold water, but is extracted by boiling water. A similar action was not observed in the case of a 30 per cent. solution of sodium hydroxide. Quartz vessels have also the power of absorbing small quantities of certain dye-stuffs (Methylene Blue, Congo Red, Rhodamine, Aniline Blue, Indocin) from their solutions. A.S.

INORGANIC QUALITATIVE.

Diphenylamine: Reaction of — with Nitric Acid. I. Bay. Comptes rend., 1905, 140, 796—797.

THE deep blue coloration produced by the action of nitric acid on diphenylamine sulphate, which has been looked upon as a characteristic reaction for nitric acid, is also observed on oxidising diphenylamine by means of a number of other oxidising agents, and also by long exposure to the atmosphere. It is pointed out that, in general, all aromatic amines give rise to more or less highly coloured oxidation products.—T. F. B.

Ammonia: New Test for —. A. Trillat and Turchet. Bull. Soc. Chim., 1905, 33, 304—308.

THE black precipitate or coloration due to the production of nitrogen iodide by the action of iodine on ammonia may serve as a delicate test for the presence of the latter, and for its determination colorimetrically. The direct use of iodine is not convenient, since the reaction between iodine and ammonia does not take place when only traces of ammonia are present. But if iodine chloride be employed in presence of a base, the reaction is very delicate, and affords an appreciable coloration with only one part of ammonia per 500,000. The best method for applying the test consists in producing the iodine chloride *in situ* by the action of an alkali hypochlorite upon potassium iodide; the liquid to be tested should be approximately neutral. It should be borne in mind that the precipitate of nitrogen iodide is soluble in excess of either of the two reagents, and that an excess of potassium iodide is especially to be avoided, since the liberation of iodine from the latter is liable to lead to confusion. In doubtful cases it is advisable to extract the free iodine from the test liquid by shaking with chloroform, in which the nitrogen iodide is insoluble. It must, however, be remembered that under the influence of the chloroform, nitrogen iodide soon begins to undergo decomposition. The reaction is available for all ammonium salts, including the cyanide and sulphide, for which the Nessler test is inapplicable.—J. F. B.

INORGANIC QUANTITATIVE.

Nitric Acid: Gravimetric Determination of — by means of "Nitron." A. Guthier. Z. angew. Chem., 1905, 18, 497—499.

THE author has investigated the solubility of nitron nitrate in water. He obtains and treats the precipitate nearly according to the directions of Busch (this J., 1905, 292) except that the liquid after precipitation is allowed to cool to the room temperature before immersion for 1—1½ hours in ice-water, and the precipitate is never sucked dry by the pump till the whole has been completely rinsed in from the beaker to the crucible by portions of the filtrate, and after sucking dry is at once washed with 10—12 c.c. of ice-cold water, 1 c.c. at a time. He finds that the washing involves a loss which would make the results too low by 0.1—0.25 per cent.; but there is evidently some compensating error, for many, both of Busch's and of his own results, are practically correct.

Determinations carried out by the author show the method gives very good results not only with potassium nitrate alone, but also with mixtures of the nitrate with potassium permanganate and bichromate, calcium magnesium sulphates, potassium and sodium chlorides, and potassium bichromate, potassium chloride, calcium carbonate, potassium chloride and bromide iodides be present, they must be destroyed by the addition to the boiling solution of potassium iodide and acetic acid, till all the iodine is boiled off. The method said to be not only accurate, but convenient, and not but little practice to obtain good results.—J. T. T.

Thorium and the Cerite Earths: Separation of — Normal Sodium Sulphite. H. Grossmann. Z. Chem., 1905, 44, 224—236.

THE trivalent cerite earths are quantitatively precipitated as normal sulphites by normal sodium sulphite, thorium and zirconium give gelatinous precipitates, basic sulphites, readily soluble in excess of the reagent. Two double alkali thorium sulphites were isolated, $\text{Th}_2(\text{OH})_2(\text{SO}_3)_2 \cdot 2\text{Na}_2\text{SO}_3 + \text{aq}$ and $\text{Th}(\text{OH})_2\text{SO}_3 \cdot 2\text{Na}_2\text{SO}_3 + \text{aq}$. The method proposed by Chavastelon (this J., 1902) for the separation of thorium from cerium by means of sodium sulphite, is of no use when only a small proportion of thorium is present, as, for example, in monazite. From dilute solutions of thorium nitrate, a basic sulphite is precipitated by normal ammonium sulphite; zirconium gives, with excess of this reagent, a clear solution from which after 12 hours, gelatinous ammonium-zirconium sulphite separates. The solubility of the hydroxides of the monazite earths in aqueous sulphurous acid decreases in the following order: cerium, didymium, lanthanum, thorium. The normal sulphites are precipitated from solutions by warming in presence of free acid.—A.

Glass Works: Analytical Methods used at the Saint-Lambert. A. Leerenier. Bull. Soc. Chim. Belg., 1904, 18, 404—412.

Sand.—Fineness is determined, as this is a measure of the rapidity of melting. Iron is determined in the way after fusion of 2 grms. of the sand with 9 grms. of sodium potassium carbonate in a platinum crucible. A very pure sand will contain 0.005 to 0.015 per cent. of ferric oxide. For goblet making it may contain up to 0.040 per cent. of ferric oxide.

Alumina, lime and magnesia are determined after volatilising silica with hydrofluoric acid in the presence of a little sulphuric acid.

Soda.—The product obtained by the ammonium process is usually employed. Sodium carbonate is determined as usual. Iron as under *Sand*.

Potash.—The ordinary methods are used except for iron, which is determined as above.

Limestone.—Organic matter and insoluble residues are determined by dissolving 100 grms., collecting the residue on a tared filter, weighing and igniting. The loss in weight corresponds to the organic matter. Sulphate, phosphate and bases are looked for in the solution.

Lead.—For iron, 20 grms. of the sample are dissolved in a slight excess of nitric acid, and the liquid is neutralised to 250 c.c. with water, and the lead determined by precipitation with potassium chromate. The solution is filtered through a dry filter and evaporated to dryness. The residue is dissolved in 1 c.c. of hydrochloric acid and a little water, the solution diluted to 500 c.c.; a measured volume of potassium thiocyanate solution is then added, and the obtained matched against that given by a blank which a solution of ferric chloride is gradually added. Copper is determined in a similar manner by comparison of its ammoniacal solution with a standard tint.

Glass.—The glass is decomposed by hydrofluoric sulphuric acids, and the various bases determined as usual. If lead be present, it cannot be left directly as residue as sulphate, as it retains large quantities of sodium sulphate; hence, it is necessary to dissolve the sulphate in hydrochloric acid, and precipitate lead, tin, with arsenic and antimony, as sulphide.

Potassium nitrate.—This should not contain more than 0.02 per cent. of impurities. Sodium chloride is determined as usual.

Tragacanth Powder, *Rapid and Sensitive Method for the Detection of Gum Arabic in —*. E. Paget. Ann. Chim. anal. appl., 1905, 10, 63. Chem. Centr., 1905, 1, 967.

A cold solution of the sample (1:30) is shaken with an equal volume of a 1 per cent. solution of gum arabic and a drop of hydrogen peroxide. If gum arabic be present, an immediate brown coloration is produced. The reaction is caused by an oxydase present in gum arabic.—A. S.

ORGANIC QUANTITATIVE.

Quinine; Solubility of — in Ammonia; and the Testing of Quinine Sulphate. W. Duncan. Pharm. J., 1905, 74, 438–440.

EXPERIMENTS made by treating saturated solutions of quinine sulphate with ammonia, both gaseous and in solution, show that contrary to the view generally held, ammonia diminishes the solubility of quinine in water. It was found that quinine is soluble to the extent of 1 in 22.6 of 10 per cent. ammonia and 1 in 250.5 of 32.5 per cent. ammonia, whereas the solubility in water is 1 in 1960 at 15° C., according to the U.S.P. The author recommends replacing ammonia by calcium hydroxide solution in testing the purity of quinine sulphate, and suggests also the titration of the quinine sulphate solution with calcium hydroxide solution in presence of phenolphthalein as indicator. The following examples are cited: 20 c.c. of a saturated solution of commercial quinine sulphate required 41 c.c. of calcium hydroxide solution to form a clear liquid; and 2.8 c.c. to show alkalinity with phenolphthalein. The sample was then adulterated with: (a) 1 per cent., (b) 3 per cent. and (c) 5 per cent. of cinchonidine sulphate. The volumes of calcium hydroxide solution required to form a clear solution and to show alkalinity with phenolphthalein with 20 c.c. of a saturated solution of the sample were now: (a) 45 and 3.3 c.c.; (b) 55 and 3.8 c.c.; and (c) 71 and 4.7 c.c. respectively.—A. S.

Oils; Determination of the Viscosity of Lubricating —. R. Hackel. Mitt. kaiserl. k. technol. Gewerbe-Museum in Wien, 1905, 15, 44–51.

THE author's experiments with an officially standardised Engler's viscosimeter, heated by means of a gas ring or

a spirit lamp, confirm the results of previous observers who have found that when a ring burner is used the oil, the probable error at 50° C. lies within 10 limits, and at 100° C. is close to the permissible whereas in determinations in which a ring burner is used, the probable error (based on the mean of the maximum and minimum results) keeps well within the permissible limits. In order to avoid the difficulty of working without the use of a ring burner, the author devised the apparatus shown in the figure, in which the temperature is regulated without the use of either a ring or a spirit lamp. The outer ring-shaped chamber, which forms the heating bath of the viscosimeter, is connected with two other vessels (fixed at a higher level) by means of tubes fitted with taps. One of these is heated by means of a Bunsen burner, whilst the other contains a coil through which passes a current of water. Oil is placed in each of them, and it is a simple matter to add either hot or cold oil to that in the chamber, whilst an additional outlet tube with a tap is fitted in the bottom of the latter, for the purpose of withdrawing oil that has been made too hot or too cold.—C. J. M.

Gutta-percha; Detection and Determination of Bituminous Substances in —. Pontio. Ann. Chim. anal. appl., 1905, 10, 57–58. Chem. Centr., 1905, 1, 907.

THE bituminous substances used to adulterate gutta-percha are completely soluble in petroleum ether, chloroform and carbon bisulphide, but only to the extent of 38 per cent. in ether, whereas gutta-percha is completely soluble in the last-named solvent. The gutta-percha under examination is extracted with ether, the residue weighed, then extracted further with chloroform or carbon bisulphide and weighed. The percentage of bituminous substances is then calculated with the aid of the formula: $R = \frac{b}{100 - m}$

where b = the percentage required, R = the weight of residue after extraction with ether, and m = the percentage of the insoluble impurities contained in the gutta-percha.—

Lactic Acid; Volatility of — with Steam. Chem.-Zeit., 1905, 29, 363–364.

FROM experiments made in connection with the spontaneous coagulation of milk, the author concludes that while lactic acid is carried over in the distillate from aqueous solutions, the volatility increasing with the concentration of the solution, this volatility is not sufficiently great to enable the acid to be quantitatively separated from aqueous solution by this means.—

Acetone; Determination of —, by the Iodoform Reaction. G. Keppeler. Z. angew. Chem., 1905, 18, 464–465.

Vaubel and Scheuer (this J., 1905, 252) state that Messinger's method yields inaccurate results, which they attribute to the iodine titration by means of thiosulphate. They do not trace the cause of this error, but propose to substitute sodium arsenite for the thiosulphate. When the error they mention occurs, it is due, as Topf has pointed out, to oxidation of the thiosulphate to tetrathionate instead of tetrathionate. Collischonn (this J., 1905, 186) has described in great detail the precautions necessary for success in determining acetone by Messinger's method, and the author finds that the method, when the necessary precautions are attended to, gives accurate results.—J. T.

Nicotine Molybdenum Compound [Determination of Nicotine]. E. Meslénzi. Landw. Vers.-Stat., 1905, 61, 321–349. Chem. Centr., 1905, 1, 904–9.

ON adding a 20 per cent. solution of ammonium molybdate to an acetic acid solution of nicotine, tetra-ammonio-diacid dinicotine ammonium molybdate (shortly, ammonium molybdate) is produced. The compound consists of white microscopic prisms decomposing at 160° C., melting, insoluble in cold water, ether, alcohol, benzene, chloroform and glycerol, slightly soluble in hot water.

soluble in dilute acids. It is decomposed by alkalis, proportion of molybdic acid in the compound can be determined by simply igniting it in a platinum crucible, and in a porcelain crucible by means of asbestos; no oxidation of molybdenum trioxide occurs if the bottom of a porcelain crucible be heated to only faint redness. The determination of nicotine in presence of ammonia, the author recommends triturating 0.25 gm. of substance with 5 c.c. of dilute potassium hydroxide solution and 15–20 grms. of burnt gypsum, extracting the mass with 2 hours with anhydrous ether, shaking the extract with 10 c.c. of 15 per cent. pure hydrochloric acid, evaporating off the ether, dissolving the residue in 96 per cent. alcohol, precipitating with platinum chloride, and filtering the amount of nicotine from the weight of platinum contained in the precipitate: 1 equivalent of platinum = 1 equivalent of nicotine.—A. S.

V.—SCIENTIFIC & TECHNICAL NOTES.

Transformations of Multirotatory ——. *Compt. Rend. Bull. Soc. Chim.*, 1905, 33, 337–348.

The modifications of dextrose, galactose, lactose and sucrose, α , β and γ have been recognised (see Armstrong, *ibid.*, 1904, 388). The author now brings direct proof that the stable β -modification is a mixture of the α - and β -forms, and he proposes to call the stable form ϵ instead of β and to use the term β for the form hitherto known. This change brings the two dextroses α and β (formerly α and γ) into correspondence with the methylglucosides α and β . The exact composition of the solution of the stable rotatory power depends on the concentration, temperature, and it is the variation of this equilibrium which accounts for the variation of rotatory power according to these conditions. The two dextroses α and β can be completely converted one into the other in the solid state under conditions where the equilibrium cannot be maintained by the prolonged action of heat or small proportions of moisture. Long heating of amorphous fused dextrose at 100°C. converts it into the β -modification, and the isolation of the latter is comparatively rapid if small portions of this modification are sown. Small proportions (e.g. up to 10 per cent.) will in time transform the whole of the β -dextrose into α -dextrose. Galactose is especially sensitive to the influence of moisture.

—J. F. B.

Chemical Action of ——. J. Ciamician and P. Silber. *Ber.*, 1905, 38, 1176–1184.

The authors now give a continuation of their previous experiments on the reduction of nitrobenzene by the aid of this J., 1904, 138, 341). On exposing a mixture of parts of nitrobenzene and benzaldehyde to the action of light for a long time, dibenzoylphenylhydroxylamine and benzoic acid are the principal products, but in addition to these, benzoylphenylhydroxylamine, dibenzylaminophenol, benzoyl- α -aminophenol, benzanilide, benzene, and α -oxyazobenzene are also obtained in small quantities. The last two compounds increase in quantity when the time of decomposition is very long.—B. J. S.

Ethylate. P. Nicolardot. *Comptes rend.*, 1905, 140, 857–858.

The author states that the soluble product of the reaction of ethylate and alcoholic ferric chloride is not ferric ethylate as previously supposed by Grimaux (*Comptes Rend.*, 1884, 98, 105); but merely a soluble double compound of the hydroxides of sodium and iron, similar to which the author has recently shown to be formed in aqueous solution (*Comptes rend.*, 1905, 140, 310). A report of this the results of a large number of determinations of the proportions of iron and chlorine precipitated when sodium ethylate is added to a solution of ferric chloride, are given.—B. J. S.

New Books.

NEW GERMAN TARIFF AS MODIFIED BY TREATIES. Statement showing (1) The New German "General" Customs Tariff. (2) The Modifications made in that Tariff by each of the New German Treaties with Russia, Switzerland, Italy, Roumania, Belgium, Austria-Hungary, and Servia. (3) The New German "Conventional" Tariff Resulting from all these Modifications; with comparison with the existing German rates of duty on Imports from the United Kingdom. Presented to Parliament by Command of His Majesty. Eyre and Spottiswoode, Printed for His Majesty's Stationery Office, London, 1905. Price 1s. 10d. To be purchased directly or through any bookseller, from Wymann and Sons, Ltd., Fetter Lane, London, E.C. and 32, Abingdon Street, Westminster, S.W., or Oliver and Boyd, Edinburgh, or E. Ponsonby, 116, Grafton Street, Dublin.

The classes of goods referred to and included in this Tariff are as follows:—(1) Agricultural and forest produce, and other natural, animal, and vegetable produce, food-stuffs, &c. (2) Mineral and fossil raw materials; mineral oils. (3) Coal tar, coal tar oils, &c. (4) Prepared wax, fatty acids, paraffin, wax wares, soap, &c. (5) Chemical and pharmaceutical products, colours, &c. (6) Animal and vegetable textile materials and wares thereof. (7) Leather and leather wares, furriers' wares, &c. (8) Caoutchouc wares. (9) Plaits and plaited goods of vegetable materials other than textile fibres. (10) Stoneware, earthenware, glass, &c. (11) Precious metals and wares thereof. (12) Base metals and wares thereof, &c. There are in this volume 227 pages of tabulated data.

MINERAL RESOURCES OF THE UNITED STATES. Department of the Interior, United States Geological Survey, Charles Walcott, Director. Calendar year 1905. DAVID T. DAY, Chief of Division of Mining and Mineral Resources. Government Printing Office, Washington. 1904.

Svo. volume containing "Letter of Transmittal," Introduction, and 1178 pages of subject matter, and the alphabetical index of the subjects. The following are the items of which geographical and industrial details are given:—I. Iron Ores: (i) Statistics of the American Iron Trade for 1903. II. Manganese Ores. III. Gold and Silver. IV. Copper. V. Lead. VI. Zinc. VII. Aluminium and Bauxite. VIII. Mercury. IX. Steel-Hardening Metals. X. Platinum. XI. Lithium. XII. Antimony. XIII. Arsenic. XIV. Tin. XV. Coal. XVI. Coke. XVII. Gas, Coke, Tar, and Ammonia at Gas Works and in Retort Coke Ovens. XVIII. Petroleum. XIX. Natural Gas. XX. Asphaltum and Bituminous Rock. XXI. Stone. XXII. Clay-Working Industries. XXIII. Cement. XXIV. Precious Stones. XXV. Talc and Soapstone. XXVI. Abrasive Materials. XXVII. Borax. XXVIII. Fluorspar and Cryolite. XXIX. Gypsum and Gypsum Products. XXX. Phosphate Rock. XXXI. Salt. XXXII. Sulphur and Pyrites. XXXIII. Barytes. XXXIV. Mineral Paints. XXXV. Asbestos. XXXVI. Flint and Felspar. XXXVII. Graphite. XXXVIII. Magnesite. XXXIX. Mineral Waters. XL. Monazite and Zircon. XLI. Glass Sand.

REPORT OF THE DEPARTMENTAL COMMITTEE ON INDUSTRIAL ALCOHOL, 1905. [Cd. 2472.] Price 3d. Wymann and Sons, Ltd., Fetter Lane, London, E.C., and 32, Abingdon Street, Westminster, S.W., or Oliver and Boyd, Edinburgh, or E. Ponsonby, 116, Grafton Street, Dublin.

This report of 27 pages contains Terms of Reference, the Report of the Committee to the Chancellor of the Exchequer, and the Report of Sub-Committee on their visit to Germany. It will be found, together with the appendices on pages 397 to 426 of this issue of the Journal.

Trade Report.

I.—GENERAL

GERMANY: TRADE OF — IN 1904.

For. Off. Ann. Series, No. 3333.

Imports.

The most notable increases in imports (over 1903) are:—

Articles.	Quantity.
	Tons.
Earths and ores	1,065,000
Coal	384,000
Copper and manufactures thereof	30,000
Instruments, machinery	32,500
Drugs, dyestuffs and chemicals	120,000
Wood, carving material, &c.	372,000
Oils and fats	63,000
Paper	24,400

Among drugs, dyestuffs and chemicals imported the principal increases were:—

	Increase.
	Tons.
Drugs, dyestuffs and chemicals—	
Nitrate of soda	39,000
Superphosphates	9,000
Ice	43,000
Oils and fats—	
Oil cake	56,000
Hog's lard	9,700
Paper—	
Swedish wood-pulp	9,600
Cellulose, &c.	19,800
Pasteboard	4,400

Exports.

The principal changes in exports relate to:—

Articles.	Increase or Decrease.
	Tons.
Cotton and manufactures of cotton	+ 6,000
Wool and manufactures of wool	+ 2,100
Manufactures of linen, jute, &c.	+ 4,300
Coal, coke and fuel	+ 815,000
Earths, ores and metals	+ 418,500
Iron and manufactures of iron	+ 711,000
Copper and manufactures of copper	+ 3,400
Zinc and manufactures of zinc	+ 5,900
Lead and manufactures of lead	+ 6,800
Instruments and machinery	+ 30,600
Drugs, dyestuffs and chemicals	+ 81,600
Wood, carving materials, &c.	+ 44,700
Oils and fats	+ 33,500
Paper	+ 5,500
Corn and agricultural produce	+ 210,200
Articles of food and drink	+ 318,200

Some of the important increases in exports of drugs, dyestuffs and chemicals are:—

Articles.	Quantity.		
	1904.	1903.	1902.
	Metric tons.	Metric tons.	Metric tons.
Aniline, &c., dyes	30,831	29,336	28,806
Chlorate of potash	140,765	125,302	106,924
Indigo (mostly artificial)	8,730	7,233	5,284
Sulphate of potash and potash magnesia	64,390	56,455	40,787

Sulphate and potash magnesia were exported to:—

Country.	Quantity.		
	1904.	1903.	1902.
	Metric tons.	Metric tons.	Metric tons.
France	4,583	5,019	1,841
United Kingdom	4,622	5,154	2,997
Netherlands	9,127	6,351	4,211
Spain	1,498	1,373	61
United States of America	37,598	33,011	27,900
Hawaiian Islands	1,524	1,168	31

Exports of chlorate of potash increased, especially to United States of America, which took 83,600 tons in 1904 compared with 70,200 tons and 61,580 tons in 1903 and 1902 respectively.

The exports of indigo were distributed as follows:—

Country.	Quantity.		
	1904.	1903.	1902.
	Metric tons.	Metric tons.	Metric tons.
Belgium	201	179	100
France	155	154	100
United Kingdom	1,168	1,055	800
Italy	450	448	300
Netherlands	494	397	300
Austria-Hungary	1,259	1,262	1,000
Russia	340	309	200
Sweden	53	74	100
Switzerland	61	86	100
Spain	72	70	100
Turkey	77	29	100
Egypt	369	170	100
India	37	50	100
China	1,171	758	100
Japan	472	342	100
United States of America	2,162	1,736	1,000

The exports of earths, ores and metals compared with exports in 1903 were:—

Articles.	Increase or Decrease.
	Tons.
Kainit and other fertilising salts	+ 130,000
Cement	+ 100,000
Sand, marl and gravel	+ 197,000
Carbonate of lime	+ 600
Porcelain earth and feldspar	+ 100
Iron ore	+ 97,000
Slag	+ 2,000
Thomas slag	+ 42,000

The remarkable falling-off in the exports of cement chiefly due to reduced shipment to the United States of America, viz., 94,100 tons, against 221,700 tons in 1903.

II.—FUEL, GAS, AND LIGHT.

CHARCOAL: U.S. CUSTOMS DECISION.

March 13, 1905.

Charcoal is dutiable at 20 per cent. *ad valorem* under section 6 of the tariff as a "manufactured article unenumerated," and not as assessed under paragraph 97 "article composed of carbon."—R. W. M.

III.—TAR PRODUCTS, PETROLEUM, Etc.

PITCH: U.S. CUSTOMS DECISION.

March 30, 1905.

Merchandise invoiced as tar, and claimed to be free of duty under various paragraphs of the tariff, and which analysis was found to be a mixture of asphaltic bitumen compounds partly sulphonated, was decided to be dutiable at 20 per cent. *ad valorem* under section 6, as a "manufactured article unenumerated."—R. W. M.

OIL (PETROLEUM) DISCOVERY IN GERMANY.

U.S. Cons. Rep., No. 2211, March 21, 1905.

December 23 last, oil was reached at a depth of 112 feet at Eickeloh, a small town on the Leine River, just at the point where this river joins the Aller. The well yields daily 16,500 litres (4,372 gall.) of oil.

OIL INDUSTRY OF INDIANA.

Eng. and Mining J., March 30.

During 1904 a large area of producing territory was added to the Indiana oilfield. This addition was made by gradual development along the margins of tested productive territory: the field, which covered 1,350 square miles on January 1, 1904, has been increased by at least 100,000 acres. About 300 new oil companies were formed and incorporated during the year, and 55 foreign companies admitted to do business in the State under the corporation law. There were 4,049 producing wells drilled during the year, and 577 dry holes.

The production of the Indiana wells in 1904 proved the highest on record. The production increased from 44 bbl. in January, to 1,065,620 bbl. in December; production for the year, 10,744,849 bbl.; valuation, \$6,688,000. The average price paid was 1.084 dol. per barrel. The owners received about 6,000,000 dol. for their oil, and the rest was received by the well owners. At the close of the year 30,540 producing wells were in operation in Indiana, a limited number of which produce gas.

VII.—ACIDS, ALKALIS, Etc.

CHEMICAL IMPORTS OF MEXICO.

For. Off. Ann. Series, No. 3332.

In 1902 the value of the chemicals and drugs imported into Mexico was \$52,594, while in 1903 the value was \$81,000.

The imports of colours, in powder or crystals and also intended for use, amounted to 101,589 lb., as compared with 100,000 lb. in 1902. Colours in powder and in solution are supplied in the following proportion:—Germany, 70 per cent.; the United States, 10 per cent.; Belgium, 8 per cent.; and the remainder from Belgium, the United Kingdom and other countries. Sixty per cent. of the prepared colours come from the United States, 10 per cent. from the United Kingdom, 10 per cent. from Germany, and the remainder from France, Belgium and other countries.

Drugs and chemicals of all kinds (including patent medicines), were imported to the value of 105,054 lb., as compared with a value of 92,345 lb. in 1902. Of the drugs and chemicals the greater part came from the United States—43 per cent.—but a very large proportion—36 per cent.—comes from France; Germany comes next with 10 per cent.

Sodium carbonate and potash were imported to the value of \$1,000,000, as compared with \$2,720,000 in the previous year. Imports of these articles come almost exclusively (90 per cent.) from the United Kingdom. It is, however, quite possible that in the next year the importation of caustic soda and potash will be much less, as the output of the paper mills is decreasing. The mills are being bought up by the paper company of San Antonio, which now supplies the market with the greatest quantity of all kinds of paper, and as the number of mills increases the consumption of caustic soda will naturally also.

SULPHUR TRADE; SICILIAN —.

Cham. of Com. J., April, 1905.

In 1904 the exports of sulphur from Sicily amounted to 100,000 tons, of which 20,957 were shipped to the United Kingdom and Malta, and about 11,000 tons to Australia and India. On December 31, 1904, the stock on hand amounted to 370,606 tons.

BARYTES. (BARIUM SULPHATE, ARTIFICIAL):

U.S. CUSTOMS DECISION. *March 29, 1905.*

Barytes was assessed for duty at one-half cent per lb. as "artificial sulphate of barytes," under paragraph 46 of the tariff. The importers claimed it to be dutiable at 75 cents or 5 dols. and 25 cents per ton, as "manufactured" or "manufactured barytes." The Board of General Appraisers found the merchandise to be artificial sulphate of barytes and affirmed the assessment of duty. — R. W. M.

MINERAL WATERS OF NICARAGUA.

For. Off. Ann. Series, No. 3337.

In the Republic of Nicaragua there are a number of hot springs, and also springs and lakes of mineral waters that may possibly be of value when the country is more fully developed. Amongst the most noticeable is the lake of Nejapa, near Managua, whose waters contain a considerable quantity of bicarbonate of potash, bicarbonate of soda, and sulphate of magnesia. This water when rubbed on any greasy object, at once forms a lather.

CHARCOAL STICKS: U.S. CUSTOMS DECISION.

March 29, 1905.

Sticks of charcoal used in chemical laboratories in connection with blowpipe analysis are dutiable under Section 6 of the tariff, as "manufactured articles, manufactured," at 20 per cent. *ad valorem*. The assessment of duty at 35 per cent. *ad valorem* as "articles composed of carbon" under paragraph 97 was overruled. — R. W. M.

VIII.—GLASS, POTTERY, AND EARTHENWARE.

GLASS POWDER: U.S. CUSTOMS DECISION.

March 25, 1905.

Powered glass of several colours, intended for decorative purposes, was held to be dutiable at 45 per cent. *ad valorem* as a "manufacture of glass," under paragraph 112 of the tariff. — R. W. M.

IX.—BUILDING MATERIALS, Etc.

CEMENT; GERMAN IMPORTS AND EXPORTS OF —, FROM 1900 TO 1904.

For. Off. Ann. Series, No. 3333.

	Quantity.				
	1904.	1903.	1902.	1901.	1900.
Imports ..	Met. tons. 60,180	Met. tons. 49,870	Met. tons. 52,018	Met. tons. 87,262	Met. tons. 79,303
Exports ..	635,247	742,381	699,378	560,612	600,386
Excess of exports	575,067	692,511	647,360	473,350	521,083

X.—METALLURGY.

IRON AND STEEL PRODUCTION: BRITISH —.

Eng. and Mining J., March 30, 1905.

The pig iron made in Great Britain last year was 8,562,658 long tons, which is a decrease of 248,546 tons, or 2.8 per cent., from 1903; but an increase of 44,965 tons, as compared with 1902. Nearly two-fifths of this iron was made with imported ore. The production of iron ore in Great Britain—lacking only a small quantity taken from quarries or shallow pits—was 9,161,588 tons, while the imports were 6,100,556 tons. Last year Spanish ore was 4,648,335 tons, or 76.2 per cent. of the total imports. The average consumption of ore was 1.78 tons per ton of iron made. With an average of 325 furnaces in blast last year, the output per furnace was 26,346 tons.

The steel production for two years has been as follows, in long tons:—

	1903.	1904.
Bessemer	1,910,018	1,781,533
Open-hearth	3,124,083	3,245,346
Total	5,034,101	5,026,879

The decrease in 1904 was made up by a decrease of 128,485 tons, or 6·7 per cent. in Bessemer, and an increase of 121,263 tons, or 3·9 per cent., in open hearth steel. The open-hearth furnace holds its own, and more, with British steel-makers. Last year open-hearth steel was 64·5 per cent. of the total. The average output of Bessemer steel per converter in use was 35,630 tons for the year, while the result from the open-hearth furnaces was 9,400 tons.

The basic process, which is confined to open-hearth work in America, is applied to the converter in Great Britain to a considerable extent. The division of steel into acid and basic in 1904 was as follows:—

	Acid.	Basic.
Bessemer	1,129,224	652,309
Open-hearth	2,583,282	662,004
Total	3,712,506	1,314,373

The basic open-hearth process has made less impression in Great Britain than in America, as shown by the figures. The proportion of acid steel last year was 73·8 per cent. of the total.

The ratio of steel to pig-iron production, which was 57·1 in 1903, increased to 58·7 in 1904. In the United States this ratio was 84·1 last year.

MERCURY PRODUCTION OF THE WORLD.

Bd. of Trade J., March 30, 1905.

The following table, showing approximately the mercury production of the world during the past two years, is extracted from the *Eng. and Mining J.* (New York):—

	1903.	1904.
	Metric tons.	Metric tons.
United States	1,288	1,480
Austria—Idria Mines	520	536
Spain—Almaden	914	1,020
Italy	314	355
Total	3,036	3,391

A metric ton is, approximately, 29·6 flasks. The total for 1904 was, therefore, about 100,374 flasks. The only producing countries of any importance not included above are Russia and Mexico, figures for which have not been received. In 1903 Mexico reported 190 and Russia 362 metric tons. Assuming that their output was about the same in 1904, and making an allowance for the smaller producers, such as Japan and Germany, a total for the year of 3,980 metric tons, or 134,460 flasks of mercury, would be arrived at.

XII.—FATS, FATTY OILS, Etc.

SOAPS AND OILS IN CYPRUS.

Bd. of Trade J., April 13, 1905.

The island produces several plants which yield essential oils, and, with cultivation, could grow much more. Some origanum oil has been distilled under contract with the Agricultural Department, from wild thyme. The small soap factory at Limassol does not make use of any essential oils, and prepares only household soap. The olive oil used is imported. The reason for this is that the oil required in soap making is obtained from the residue which remains after the oil has been extracted from the olives. No

olive oil producer in Cyprus possesses the necessary apparatus for treating this residue. A co-operative soap factory, distilling essential oils from island grown plants, utilising the olive oil produced from the trees belonging to the co-operators themselves, should have a good prospect of success.

XIII. A.—PIGMENTS, PAINTS, Etc.

ROUGE: U.S. CUSTOMS DECISION.

March 30, 1905.

Rouge for polishing purposes, consisting of 96·4 and 98·93 per cent. of oxide of iron, is dutiable at 30 per cent. *ad valorem* as a "colour" under paragraph 58 of the tariff. The Board held that it was a colour regardless of the to which it is applied.—R. W. M.

XIV.—TANNING: LEATHER; GLUE,

HIDE POWDER: U.S. CUSTOMS DECISION.

March 13, 1905.

Merchandise invoiced as "Chromirtes Hautp" consisting of dry powdered raw hide and oxide of chromium, was decided to be dutiable at 25 per cent. *ad valorem* as a "chemical compound" under paragraph of the tariff. The Board overruled the claim importer that it was dutiable at 20 per cent. *ad valorem* under section 6 as a "manufactured article" merated.—R. W. M.

XVI.—SUGAR, STARCH, Etc.

SUGAR FROM SPAIN PROHIBITED.

Bd. of Trade J., March 30, 1905.

An Order in Council has been published, dated 27, 1905, providing that whereas it appears from a report of the Permanent Sugar Commission that a bounty production or export of sugars is granted in Spain for sugar from Spain (not including molasses and sweetened products) shall (except in transit) be prohibited to be imported into the United Kingdom from after April 3 next.

SUGAR EXPORTS OF GERMANY.

For. Off. Ann. Series, No. 3333.

The exports of sugar for the last three calendar years are:—

	Quantity.		
	1904.	1903.	1902.
	Metric tons.	Metric tons.	Metric tons.
Sugar of all kinds—			
Raw	320,704	461,165	491,165
Other	459,736	559,023	577,023
Total	780,440	1,020,194	1,072,240

ARROWROOT STARCH: U.S. CUSTOMS DECISION.

March 30, 1905.

Arrowroot, consisting of the starch extracted from the tubers of the arrowroot plant, is dutiable as "starch" at 1½ cents per pound, under paragraph 285 of the tariff. The Board held that the provision for "starch" was more specific than that for "arrowroot."—R. W. M.

XVII.—BREWING, WINES, SPIRIT, Etc.

METHYLATED SPIRIT IN SWITZERLAND.

Chem. and Drug., April 15, 1905.

Since January 1, 1905, methylated spirit has been obtained in Switzerland exclusively from the Confederation.

Administration. Previously firms were able to methylated spirit on payment of the duties. In no foreign alcohol will be admitted into Switzerland unless addressed to the Confederated Spirit Administration.

SAKE: U.S. CUSTOMS DECISION.

March 3, 1905.

United States Circuit Court of Appeals has decided saké is dutiable at 20 per cent. *ad valorem* as a manufactured article unenumerated under section 6 of the tariff. The Court held that saké is similar to beer in material and use, and also similar to still wine in manufacture and use, but has also characteristics not found in either. Hence it does not resemble either beer or wine sufficiently to establish a similitude to either for the purposes of tariff classification.

Treasury Department has decided to appeal to the United States Supreme Court against this decision. The decision of the appeal, duty will be levied at 20 cents per gallon under paragraph 296, as a still wine. Amount involved is estimated at 500,000 dols.

—R. W. M.

XX.—FINE CHEMICALS, Etc.

OIL AND RESINOID: U.S. CUSTOMS DECISIONS.

March 20 and 24, 1905.

Oil concrete and resinoid of orris are dutiable at 30 per cent. *ad valorem* as "essential oils" under paragraph 3 of the tariff. The claim of the importer that oil of orris was free of duty as "enfleurage grease" under paragraph 626, was overruled. The evidence showed the orris root was extracted by a volatile solvent in the same manner as enfleurage grease, but that the resulting product or resin of orris had been treated separately by distillation to obtain the white concrete oil of orris. The evidence also showed that the resinoid was the result of a process of distillation.—R. W. M.

ETHERS IN SWITZERLAND.

Chem. and Drug., April 15, 1905.

Feuille Federale Suisse of February 22 contains text of a notification of the Federal Department of Commerce, announcing that from February 20 monopoly-duty (duty on the import-duty) will be levied on certain ethers, on importation into Switzerland, at the following rates:—Alcoholised ether (Hoffmann's spirit), at 100 kilos.; nitric ether, 90f.; and formic ether, at 100f.

ETHER (AMYL ACETATE): U.S. CUSTOM DECISION.

March 30, 1905.

Liquid for the Hefner Alteneck lamp, which, on importation, was found to be pure amyl acetate, was held dutiable at 2 dols. per pound as a "fruit ether" under paragraph 21 of the tariff.—R. W. M.

I.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

PHOTOGRAPHIC PAPER EXPORTS OF GERMANY.

For. Off. Ann. Series, No. 3333.

Exports of photographic paper have increased very much during the last three years. The figures are:—

Year.	Quantity.	Value.
	Metric tons.	£
1904	1,644	891,250
1903	1,218	660,550
1902	474	284,700

Of which there were shipped to—

	Quantity.		
Country.	1904.	1903.	1902.
	Metric tons.	Metric tons.	Metric tons.
United Kingdom	627	572	129
Belgium	235	26	10
United States of America	333	235	51

PHOTOGRAPHIC PLATES: U.S. CUSTOMS DECISION.

March 31, 1905.

Photographic dry plates of glass, which have been exposed abroad in a photographic camera, are dutiable at 45 per cent. *ad valorem*, as "manufactures of glass," under paragraph 112 of the tariff.—R. W. M.

Patent List.

N.B.—In these lists, [A.] means "Application for Patent," and [C.S.] "Complete Specification Accepted."

Where a Complete Specification accompanies an Application, an asterisk is affixed. The dates given are (i) in the case of Applications for Patents, the dates of application, and (ii) in the case of Complete Specifications Accepted, those of the Official Journals in which acceptances of the Complete Specifications are advertised.

Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the said dates.

- .. 28,424 (1904). Vial. Vaporising apparatus. April 19.

II.—FUEL, GAS, AND LIGHT.

- [A.] 6433. Morton and Crosta. Gas producers and similar apparatus. March 27.
- .. 6434. Crosta and Morton. Gas producers. March 27.
- .. 6563. Wilton. Treatment of gases produced in the destructive distillation of coal or other carbonaceous material for the purification thereof and recovery of bye-products, and apparatus for use therein. March 28.
- .. 6693. Bölling. Process for producing moulded blocks of silicon or boron carbide.* March 29.
- .. 6753. Darch and Marriott. Manufacture of artificial fuel. March 30.
- .. 6780. Leadbeater. Artificial fuel. March 30.
- .. 6794. Bell. Apparatus for the manufacture of gas. March 31.
- .. 7307. Wall. Apparatus for the manufacture of gas suitable for heating and illuminating purposes. April 6.
- .. 7310. Capitaine. Process for maintaining the temperature in a gas producer working with a varying consumption of gas. [Ger. Appl., April 9, 1904.]* April 6.
- .. 7324. Cutler. Gas purifiers. April 6.
- .. 7499. Thomas. Means for treating coal smoke. April 8.
- .. 7713. Elworthy and Williamson. Manufacture of gas for illuminating, heating or power purposes. April 11.

- [C.S.] 1738 (1904). Whittfield. Process and apparatus for the manufacture of combustible gas from water and like substances. April 5.
- .. 7347 (1904). Thwaite. Generating combustible gas from hydrocarbonaceous and other solid materials. April 5.
- .. 7592 (1904). Radcliffe. Gas generators and apparatus for the manufacture of gas. April 5.
- .. 8492 (1904). Hodge. Gas purifiers. April 11.
- .. 9396 (1904). Reese. Gas producer. April 11.
- .. 9668 (1904). Lynn. Gas producers. April 11.
- .. 10,926 (1904). Dempster and Sons, Ltd., and Gas retorts. April 5.
- .. 11,719 (1904). Hills and Schill. Producer apparatus. April 12.
- .. 12,247 (1904). Carolan (General Electric Co.). Electrodes and lamps for arc lighting. April 5.
- .. 13,161 (1904). Carolan (General Electric Co.). Manufacture of filaments for incandescent lamps. April 19.
- .. 16,427 (1904). Browne and McKinlay. *See under I.*
- .. 24,064 (1904). Onslow. Gas burners for heating purposes. April 19.
- .. 28,765 (1904). Marchal. Purifying or desulphurising lighting gas. April 5.
- .. 257 (1905). British Thomson-Houston Co. (General Electric Co.). Electric arc lamp electrodes. April 12.
- .. 616 (1905). Deuts. Continental Gas-Ges. Gas burners. April 5.

III.—DESTRUCTIVE DISTILLATION, TARS, PRODUCTS, PETROLEUM, AND MINERAL WAXES.

- [A.] 6798. Garroway. Preparation of acetic acid, acetone, and methyl alcohol. March 31.
- .. 7630. Henderson. Apparatus for treating paraffin wax. April 11.
- .. 7699. Van der Ploeg. Manufacture of emulsions of heavy mineral oils or the like. April 11.
- [C.S.] 10,466a (1904). Dreyman. *See under XVII A.*
- .. 23,680 (1904). Rud. Rütgers Chem. Fabrik f. Tarprodukte. Treatment of heavy tar oils for the manufacture of pitch or of a special kind of oil. April 12.

IV.—COLOURING MATTERS AND DYESTUFFS.

- [A.] 7002. Imray (Meister, Lucius und Brüning). Manufacture of a bisulphite compound of a certain dyestuff. April 3.
- .. 7022. Johnson (Badische Anilin und Soda Fab.). Manufacture of compounds of the anthracene series and colouring matters therefrom. April 3.
- .. 7390. Imray (Meister, Lucius und Brüning). Manufacture of indigo pastes. April 7.
- .. 7835. Johnson (Dye Works, formerly Durl, Huguenin and Co.). Manufacture of leuco-guanine dyes.* April 12.
- .. 7838. Oehler. Production of indophenolsulphonic acids. [Ger. Appl., Nov. 30, 1904.]* April 2.
- .. 7839. Lake (Oehler). Production of blue monoazo dyes.* April 12.

910. Abel (Act.-Ges. f. Anilinfabr.). Manufacture of 5-nitro-2-amidophenol and of colouring matters derived therefrom. April 13.

936. Ransford (Cassella and Co.). Manufacture of naphthylencurea-oxysulphonic acid and of dyestuffs therefrom. April 15.

363 (1904). Imray (Soc. Chem. Ind. in Basle). Manufacture of new amidothioalphenyl derivatives and of new dyestuffs therefrom. April 5.

363 (1904). Lake (Oehler). Manufacture of mono-azo dyes. April 12.

1,863 (1904). Ellis (Chem. Fabr. vorm. Sandoz). Manufacture of green sulphur dyes. April 12.

1,956 (1904). Johnson (Badische Anilin und Soda Fabrik). Manufacture of hydroxyethylaniline and derivatives thereof. April 19.

97 (1905). Imray (Dye Works, formerly Durand, Huguenin and Co.). Manufacture of new dyestuffs derived from dyestuffs of the oxazine class. April 5.

64 (1905). Johnson (Badische Anilin und Soda Fabrik). Manufacture of phenylglycine salts. April 12.

61 (1905). Johnson (Badische Anilin und Soda Fabrik). Manufacture of azo colouring matters. April 19.

-PREPARING, BLEACHING, DYEING.

ING AND FINISHING TEXTILES, YARNS, AND FIBRES.

49. Hearn and Jehu. Printing in multi-colours or tones. March 27.

95. Johnson (Badische Anilin und Soda Fabrik). Printing indigo on vegetable fibre.* March 27.

45. Armitage. Finishing certain fabrics. Mar. 29.

13. Sterne-Price. Method of bleaching, cleaning, and treatment of ramie. March 30.

20. Kother. *See under XI.*

70. Stalker. Method of dyeing or colouring fibres, yarns, threads and textiles, also applicable to the dyeing or colouring of leather and feathers. April 5.

31. Riep and Baner. Greasing medium for fibrous materials and woven fabrics.* April 5.

56. Tait. Treating and dressing flax and other fibres.* April 10.

92. Johnson (Badische Anilin und Soda Fabrik). Manufacture of discharging agents. April 10.

18. Lake (Cottrell and Sons Co.). Art of colour printing.* April 11.

17. Delhotel. Process and apparatus for regaining the benzine employed for cleaning fabrics. [Fr. Appl., July 16, 1904.] April 12.

33. Lennox. *See under I.*

46. Atkinson and The Calico Printers Association, Ltd. Production of photo-engraved surfaces for printing textile fabrics. April 15.

11 (1904). Palmer. Figuring or shading of velvet. April 19.

10 (1904). Partridge. Machines for dyeing yarns and slubbings. April 12.

736 (1904). Bernhardt. Potash leaching apparatus for raw wool. April 5.

[C.S.] 13,484. (1904). Dolder. Process for dyeing cotton and the like in the form of cops, spools and so forth with alizarin red. April 19.

13,867 (1904). Muntadas y Rovira. Process and apparatus for the bleaching of fabric and yarn. April 12.

16,105 (1904). Möller-Holtkamp. Dressing or sizing of yarns. April 19.

25,703 (1904). Scharmann. Apparatus for dyeing, bleaching, boiling and rinsing textile fabrics, &c. April 12.

25,704 (1904). Scharmann. Apparatus for dyeing and treating textile materials and fabrics. April 12.

27,565 (1904). Crespín. Process and apparatus for the manufacture of artificial silk, horse hair, ribbon, or straw. April 19.

6495 (1905). Johnson (Badische Anilin und Soda Fabrik). Printing indigo on vegetable fibre. April 19.

VI.—COLOURING WOOD, PAPER, LEATHER, Etc.

[A.] 7170. Stalker. *See under V.*

VII.—ACIDS, ALKALIS, AND SALTS.

[A.] 6439. Waltze. Process for manufacturing lead carbonates. March 27.

6448. Bastian and Calvert. Method of treating a gas or gases by catalysis and catalyser therefor. March 27.

6585. Deuts. Gold- und Silber-Scheide Anstalt, vorm. Rössler. Manufacture of sodium perborate. [Ger. Appl., June 11, 1904.]* March 28.

6611. Tec. Manufacture of white salt from rock salt. March 29.

6700. Gittings. Acids. March 30.

6759. Westhauser. Manufacture of hydrochloric and hydrobromic acids. March 30.

6796. Edwards. Table salt. March 31.

6798. Garroway. *See under III.*

7030. Cie. des Prod. Chimiques d'Alais et de la Camargue. Calcination of hydrated alumina. [Fr. Appl., April 8, 1904.]* April 3.

7034. Paramore. Treating and utilising chlorine gas.* April 3.

7062. Brownsdon. *See under X.*

7549. Spence, Spence, and Peter Spence and Sons, Ltd. Production of alum. April 10.

7616. Cornillanx. Extraction and purification of sulphur.* April 10.

7916. Driffield and The United Alkali Co., Ltd. Purification of sulphuric acid. April 13.

8057. Van Schwarz. *See under X.*

[C.S.] 12,634 (1904). Bloxam (Tcherniac). Treatment of ferrocyanides to obtain hydrocyanic acid. April 12.

14,464 (1904). Lake (Chem.-Techn. Fabrik, Dr. A. R. W. Brand und Co.). Recovery of carbonic acid from waste gases. April 19.

VIII.—GLASS, POTTERY, AND ENAMELS.

[A.] 6699. Gittings. Manufacture of precious stones. March 30.

7086. Turner. Decoration of ceramic ware. April 4.

- [C.S.] 9776 (1904). Richardson. Process and apparatus for the manufacture of glass. April 5.
 „ 3906 (1905). Johnson (Heraeus). Manufacture of quartz glass. April 5.

IX.—BUILDING MATERIALS. CLAYS, MORTARS, AND CEMENTS.

- [A.] 6546. Barratt, and The United Asbestos Co., Ltd. Coverings and linings for lessening conduction of heat.* March 28.
 „ 7043. Wolman. Composition for impregnating wood. April 3.
 „ 7267. Moore. Composition for making refractory bricks, furnace linings, tuyères, retorts, crucibles, &c. April 6.
 „ 7268. Moore. Composition for making refractory bricks, furnace linings, tuyères, retorts, crucibles, and the like. April 6.
 „ 7521. Brodie. Treatment of the clinker from refuse destructor furnaces. April 10.
 „ 7537. Wynne. Manufacture of cement from blast furnace slag. April 10.
 [C.S.] 9680 (1904). Lake (Juncquel and Hayn). Manufacture of building materials, heat insulating materials and the like. April 5.
 „ 9706 (1904). South. Bricks. April 5.
 „ 28,729 (1904). Weed. Treating wood for preserving and like purposes. April 12.

X.—METALLURGY.

- [A.] 6468. Soc. Electro-Metall. Française. *See under XI.*
 „ 6698. Gittings. Manufacture of metals. March 30.
 „ 6804. Richard. Compositions and metallic bars for indicating temperatures in kilns, ovens, &c. March 31.
 „ 6931. Newton (Falding). Roasting furnaces.* April 1.
 „ 7062. Brownson. Production of metallic mercury and of mercury sulphide from ores of mercury and other mercurial compounds. April 4.
 „ 7098. Hommel. Extraction of metals from ores or compounds. April 4.
 „ 7114. Saunders. Apparatus for separating gold and other metals from their ores. April 4.
 „ 7131. Weiller and Weiller. Process for extracting copper from copper ore, more particularly from poor copper ore.* April 4.
 „ 7144. Sulman, Picard and Ballot. Ore concentration. April 4.
 „ 7154. Perry. Cleaning of tin slags in the blast furnace. April 5.
 „ 7332. Cowper-Coles. Manufacture of metallic calcium. April 7.
 „ 7525. Cowper-Coles. Manufacture of zinc dust. April 10.
 „ 7624. Griesbach. Utilising tinplate scrap and other waste tinned goods and the like. April 11.
 „ 7660. MacIvor and Fradd. Treatment of sulphide ores containing zinc. April 11.

- [A.] 7714. Elworthy and Williamson. Production of nickel. April 11.
 „ 7803. Sulman, Picard and Ballot. Ore concentration. April 12.
 „ 7915. Best, Hollingsworth, and The United Co., Ltd. Apparatus for the treatment of refractory ores. April 13.
 „ 8037. Cowper-Coles. Zinc alloys. April 13.
 „ 8057. Van Schwarz. Gas furnace for calcining ores, limestone, magnesite, and the like. April 13.
 [C.S.] 7902 (1904). Defays. Reverberatory furnace. April 5.
 „ 8605 (1904). Webb. Filtering apparatus for the extraction of water from finely-crushed materials. April 12.
 „ 9482 (1904). Nan. Process of refining metals. April 5.
 „ 19,053 (1904). Massenez. Manufacture of steel by the basic bessemer process. April 5.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

- [A.] 6468. Soc. Electro-Metall. Française. Production of cast iron, more particularly a view to the manufacture of steel. [E. A. Oct. 24, 1904.]* March 27.
 „ 6650. Schenk. Galvanic cells.* March 29.
 „ 6786. Gerard and Fiedler. Plates for electrolysis.* March 30.
 „ 6790. Potthoff. Apparatus for electrolysis. March 30.
 „ 6872. Wood-Smith. Apparatus for the electrolysis of gases. March 31.
 „ 7004. Reynolds. Electric furnaces. April 3.
 „ 7020. Kother. Electrodes for electrolysis in the manufacture of bleaching powder. April 3.
 „ 7101. Hemptinne. *See under I.*
 „ 7133. Fellows, Pickup and Tice. Electric motive battery. April 4.
 „ 7534. Wynne. Heating by electricity. April 11.
 „ 7720. Leitner. Manufacture of accumulators. April 11.
 „ 7903. Fennell and Perry. Electric accumulators or secondary electrolytic cells. April 13.
 [C.S.] 7814 (1904). Bauer (Dutertre and Nodet). Electro-roasting and heating apparatus. April 5.
 „ 10,559 (1904). Siemens Bros. and Co., Ltd. and Eichenauer. Galvanic batteries. April 5.
 „ 10,881 (1904). Carolan (Gen. Electric Co.). Method of conducting chemical reactions by means of mercury vapour arc. April 5.
 „ 13,223 (1904). Holden, and Chamberlain and Ham. Electrolytic meters. April 12.
 „ 13,952 (1904). Inray (Soc. Anon. d'Etude Elect. Chimiques). Apparatus for submitting gases and vapours to the action of the electric arc. April 12.
 „ 27,901 (1904). Gardiner. Storage cells. April 12.
 „ 28,601 (1904). King. Apparatus for the deposition of metals. April 12.

315 (1905). Thompson (Pflüger Accumulatoren-Werke). Plates for secondary batteries. April 19.

3798 (1905). Goodson. Process of galvanising, tinning, and otherwise plating wire and other metallic bodies. April 19.

I.—FATTY OILS, FATS, WAXES, AND SOAP.

1967. Rivers. Glycerine compound. April 3.

7646. Buchanan. Apparatus for heating linseed oil. April 11.

10,466 (1904). Dreyman. Production of fatty acids such as are used in the manufacture of candles, lamp-oils, cooking fats, soaps, and the like. April 12.

10,466A (1904). Dreyman. *See under XVIII. A.*

II.—PIGMENTS, PAINTS; RESINS, VARNISHES; INDIA-RUBBER, Etc.

(A.)—PIGMENTS, PAINTS.

7935. Ransford (Cassella und Co.). Manufacture of colour lakes. April 13.

10,895 (1904). Johnson (Badische Anilin und Soda Fabrik). Manufacture of colouring matter lakes. April 5.

14,634 (1904). Newton (Bayer und Co.). Manufacture of new colour lakes. April 12.

27,757 (1904). Giband and Bang. White pigment. April 19.

(B.)—RESINS, VARNISHES.

751. Lederer. Solutions of organic compounds suitable as lacquers, varnishes, waterproofing and impregnating media, and for the manufacture of films, filaments and insulating materials. March 30.

750. Bell. Antifouling substances for ships. April 12.

(C.)—INDIA-RUBBER.

129. Lawrence. Process of cleaning rubber.* April 4.

694. Morisse. Treatment of the milks or lactiferous juices of caoutchouc, gutta-percha, balata and the like.* April 11.

705. Morisse. Process for the direct utilisation of the lactiferous juices of caoutchouc, gutta-percha and balata. April 11.

8,294 (1904). Petersen. Process for reclaiming and regenerating rubber. April 19.

III.—TANNING; LEATHER, GLUE, SIZE, Etc.

788 (1904). Faucheux and Boissière. Manufacture of gelatine and glue. April 19.

6,888 (1904). Hannemann. Non-desiccating depilatories. April 19.

XVI.—SUGAR, STARCH, GUM, Etc.

[A.] 7334. Holoubek. Manufacture of lignine, starch, amyloid and dextrose or alcohol from wood, cotton and other waste, peat and other fibrous vegetable matters. April 7.

XVII.—BREWING, WINES, SPIRITS, Etc.

[A.] 7725. Hunt. Manufacture or purification of whiskey and other spirits. April 11.

.. 7963. Lennox. *See under I.*

XVIII.—FOODS; SANITATION, WATER PURIFICATION; & DISINFECTANTS.

(A.)—FOODS.

[A.] 6457. Fränkel. Manufacture of a malt food. March 27.

.. 7922. Héritte. Alimentary extracts of blood. April 13.

.. 7982. Glas. Manufacture of soluble milk powder. [Ger. Appl., May 17, 1904.]* April 14.

.. 8013. Taylor. Manufacture of food.* April 14

.. 8014. Taylor. Preparation and preservation of cream and similar fatty substances or emulsions.* April 14.

.. 8015. Taylor. Ferruginous foods.* April 14.

[C.S.] 10,466A (1904). Dreyman. Utilisation of fatty acid esters as alimentary fats, illuminating oils, ointment bases, and the like. April 19.

(B.)—SANITATION; WATER PURIFICATION.

[A.] 7521. Brodie. *See under IX.*

.. 7963. Lennox. *See under I.*

XIX.—PAPER, PASTEBOARD, Etc.

[A.] 6783. Soc. Desmarais et Morane, and Denis. Means for filtering and drawing colloids and cellulose solutions. [Fr. Appl., April 26, 1904.]* March 30.

.. 6926. Claviez. Manufacture of paper threads. April 1.

.. 7140. Holken. Process for improving paper yarn.* April 4.

.. 7766. Stephan (Rolier). Manufacture of paper.* April 12.

[C.S.] 11,269 (1904). Coleman. Paper machines. April 10.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES, AND EXTRACTS.

[A.] 6719. McNicol. Production of refined saccharine. March 30.

.. 6948. Zimmermann (Chem. Fabr. auf Actien, vorm. E. Schering). Manufacture of salicylic acid glycerine formal ester. April 1.

- [A.] 7481. Hefti. Preparation of the carbamido-phenolsulphonates of amines. April 8.
- „ 7830. Langer. Process for producing blood albumin preparations.* April 12.
- „ 7840. Clemmensen and Heitmann. Hypnotic compounds.* April 12.
- [C.S.] 11,259 (1904). Abel [Act.-Ges. f. Anilinfabr]. Manufacture of derivatives of barbituric acid. April 5.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

- [A.] 6877. Mézáros. Process and means for producing pigment pictures, single or multicoloured photographs, and plastic or printing plates with a silver salt or like emulsion.* March 31.

- [A.] 7341. Jones. Manufacture of photographic printing paper. April 7.
- „ 7557. Imray (Meister, Lucius und Brüning). Manufacture of coloured photographic images. April 10.
- „ 7693. Robicek. Manufacture of gelatine emulsion papers. April 11.
- „ 7967. Thornton. Coloured photographs methods of producing same. April 14.
- [C.S.] 23,729 (1904). Lüttke, Arndt and Löwe. Photographic developers. April 12.

XXII.—EXPLOSIVES, MATCHES, Etc.

- [A.] 6651. Haddan (Roth). Explosives containing aluminium or other light metals.* March 1.
- „ 6672. James (Golovin). Manufacture of a powder for shooting and blasting purposes. March 20.

JOURNAL OF THE Society of Chemical Industry.

A RECORD

FOR ALL INTERESTED IN CHEMICAL AND ALLIED MANUFACTURES.

ISSUED TWICE A MONTH.

No. 9.—Vol. XXIV.

MAY 15, 1905.

No. 9.—Vol. XXIV.

Subscription of Members 25 s. per annum;
Entrance Fee 21 s.;
Election by the Council.

Price to Non-Members 36 s. per annum;
To Members 25 s. per Set of extra or back numbers.
Single copies (Members and Subscribers only)
1882—1901, 2 6 each; 1902 *et seq.* 1 9 each.

he Society of Chemical Industry.

THE JOURNAL.

Past Presidents:

Sir Henry E. Roscoe, B.A., D.C.L., LL.D., Ph.D., F.R.S.	1881—1882.
(Sir Frederick A. Abel, Bart., K.C.B., G.C.V.O., D.C.L., D.Sc., F.R.S.	1882—1883.
(Walter Weldon, F.R.S.	1883—1884.
W. H. Perkin, LL.D., Ph.D., F.R.S.	1884—1885.
E. K. Muspratt	1885—1886.
David Howard	1886—1887.
Sir James Dewar, M.A., LL.D., F.R.S.	1887—1888.
Ladwig Mond, Ph.D., F.R.S.	1888—1889.
(Sir Lowthian Bell, Bart., F.R.S.	1889—1890.
(E. Rider Cook	1890—1891.
(J. Emerson Reynolds, M.D. F.R.S.	1891—1892.
Sir John Evans, K.C.B., D.C.L., LL.D., Sc.D., F.R.S.	1892—1893.
(E. C. C. Stanford	1893—1894.
T. E. Thorpe, C.B., LL.D., Sc.D., Ph.D., F.R.S.	1894—1895.
Thomas Tyrer	1895—1896.
(Edward Schunck, Ph.D., F.R.S.	1896—1897.
Frank Clowes, D.Sc.	1897—1898.
George Bellby	1898—1899.
C. F. Chandler, D.Sc., M.D., Ph.D., LL.D.	1899—1900.
Sir Jos. W. Swan, D.Sc., M.A., F.R.S.	1900—1901.
Ivan Levinstein	1901—1903.
Sir W. Ramsay, K.C.B., D.Sc., LL.D., F.R.S.	1903—1904.

† Deceased.

Publication Committee: The President.

COUNCIL FOR YEAR ENDING JULY 1905.

Editor:

Watson Smith, 34, Upper Park Road, Haverstock Hill, N.W.

Assisted by the following Staff of Abstractors:

D. Bendix III.	A. G. Levy, B.Sc. VIII., IX.
E. Bentz IV., V., VI.	G. W. Macdonald, XXII.
J. O. Braithwaite XX.	M.Sc. XXI.
J. F. Briggs { XVI., XVII., XIX., XX.	N. H. J. Miller, Ph.D. XV
J. K. Burbridge XIII. C.	C. A. Mitchell, XII., XXII.
T. F. Burton, III., XX., XXI., B.Sc. Patent List.	B.A.
W. A. Caspari, Ph.D. XI.	R. W. Moore Trade Report.
W. H. Coleman I., III., VII.	Barker North V., XI.
J. H. Collins X.	T. H. Pope, XVI., XVII., B.Sc. XX., XXI.
J. T. Dunn, D.Sc. VII., X.	F. W. Renault Index.
Ernest Feilmann, IV., V., XX.	Chas. Salter { II., III., IX., B.Sc. XVI., XVII.
Leo F. Guttman, Ph.D. I., II.	M. J. Salter XIII.
Walter C. Hancock, B.A. { II., VIII., IX.	F. Sheden XX.
R. S. Hutton XI.	A. Shonk Gen. Chem.
R. L. Jenks { XIII. C., XIV., XIX.	W. P. Skertchley { XII., XVIII.
F. H. Leeds { II., III., XIII., XXI.	E. Sonstadt III., VII., X., XV.
		A. B. Steven, B.Sc. IV., V.
		E. Howard Tripp { III., VII., Ph.D. XVI.
		L. J. de Whalley, B.Sc. XVI.

President: Wm. H. Nichols, M.S., LL.D., D.Sc.	
Vice-Presidents:	
P. P. Phillips Bedson.	Ivan Levinstein.
Dr. J. G. Coblenz.	Max Muspratt.
Dr. E. Divers, F.R.S.	T. J. Parker.
Dr. W. R. E. Hodgkinson.	Dr. F. E. Power.
Dr. Grant Hooper.	Sir Wm. Ramsay, K.C.B., F.R.S.
Dr. I. Howard.	Thos. Tyrer.
Ordinary Members of Council:	
Dr. J. G. Grossmann.	B. E. R. Newlands.
Dr. G. Guttman.	Prof. W. J. Pope, F.R.S.
Dr. H. H. H. H. H.	Dr. Boverton Redwood.
Dr. W. R. Lang.	Walter F. Reid.
Dr. J. Lewkowitsch.	Frank Seudder.
Dr. J. Martin.	Dr. W. S. Squire.
Sectional Chairmen and Secretaries:	
CANADIAN. Alfred Burton.	
Dr. J. Smale.	LIVERPOOL.
Dr. Carey.	W. R. Hardwick.
Dr. Jordan Salamon.	LONDON.
Dr. Carter Bell.	Julian L. Baker.
Dr. T. Dunn.	Julius Hübner.
Dr. Russell W. Moore.	NEWCASTLE.
J. Wood.	F. C. Garrett.
R. Thomson.	NEW YORK.
Dr. A. Liversidge, F.R.S.	Dr. H. Schweitzer.
Dr. H. R. Procter.	NOTTINGHAM.
	S. R. Trotman.
	SCOTTISH.
	Dr. Thos. Gray.
	SYDNEY, N.S.W.
	T. U. Walton.
	YORKSHIRE.
	Thos. Fairley.
Honorary Treasurer:	
Samuel Hall, East London Soap Works, Bow, E.	
Honorary Foreign Secretary:	
Dr. Ludwig Mond, F.R.S.	
General Secretary: Charles G. Cresswell.	
Office: Palace Chambers, 9, Bridge Street, Westminster, S.W.	
Telegraphic Address: 59, Palatable, London.	

Official Notices.

COMMUNICATIONS.

Authors of communications read before the Society, or any of its Local Sections, are requested to take notice that under Rule 43 of the Bye-laws the Society has the right of priority of publication for three months of all such papers. Infringement of this Bye-law renders papers liable to be rejected by the Publication Committee, or ordered to be abstracted for the Journal, in which case no reprints can be furnished to the author.

ANNUAL GENERAL MEETING, 1905.

The Annual General Meeting will be held in London in July next, and the proceedings will commence on Monday, July 10th.

In accordance with the provisions of Rule 18 of the By-Laws, notice is hereby given that those members whose names are printed in *italics* in the list of Council will retire from their respective offices at the forthcoming Annual Meeting.

Dr. Edward Divers, F.R.S., has been nominated to the office of President under Rule 8; Dr. L. Baekeland, Mr. J. Carter Bell, Dr. J. Lewkowitch, and Mr. N. H. Martin have been nominated Vice-Presidents under Rule 8; and Mr. Wm. H. Nichols has been nominated a Vice-President under Rule 11.

The Hon. Treasurer and Hon. Foreign Secretary have been nominated for re-election to their respective offices.

Members are hereby invited to nominate fit and proper persons to fill four vacancies among the ordinary members of the Council. Forms for this purpose can be obtained, on application, from the General Secretary, or from the Hon. Local Secretaries of the Canadian, New York, and Sydney Sections.

Extract from Rule 18 :—"No such nomination shall be valid unless it be signed by at least ten members of the Society who are not in arrear with their subscriptions, nor unless it be received by the General Secretary, at the Society's office, at least one month before the date of the Annual General Meeting, at which the election to which it refers takes place. Nor shall any such nomination be valid if the person nominated be ineligible for election under Rules 12 or 15. No member shall sign more than one nomination form."

INDUSTRIAL ALCOHOL COMMITTEE.

The report of this Committee, which was appointed by the Chancellor of the Exchequer in September last to inquire into the existing facilities for the use, without payment of duty, of spirit in arts and manufactures, and, in particular, into the operation of Section 8 of the Finance Act, 1902, has been published, together with the minutes of evidence. The report will be found in the April 29th issue of the Journal, together with a full abstract of the Appendixes. Such of the Committee's proposals as need legislative sanction will be embodied in a Revenue Bill.

At a meeting of the Council, held on April 25th, the following resolutions were passed :—

1. "That this Council welcomes the Report of the Industrial Alcohol Committee with the Blue Book containing the evidence and appendixes upon which the Report is based, and resolves that a letter be sent thanking the Chancellor of the Exchequer for his action in appointing the Committee, and expressing a trust that he may see his way to give legislative effect to the recommendations of the Committee at an early date."

2. "That this Council also desires to record its appreciation of the persistent efforts of Mr. Thomas Tyrer in the cause of Industrial Alcohol, and hereby tenders him its thanks for his services on the Industrial Alcohol Committee."

SIXTH INTERNATIONAL CONGRESS OF APPLIED CHEMISTRY, ROME, 1906.

At a meeting of the Organising Committee of the Sixth International Congress of Applied Chemistry, held in Rome on March 2 last, Prof. E. Paternò in the course of it was decided to divide the Congress into the number of sections as was the case at Berlin in 1903. At the suggestion of the Presidents of foreign Committees the date of meeting was fixed for April, 1906, during Easter week.

All communications with respect to the Congress should be addressed to the President, Prof. E. Paternò, Via Panisperna 89, Rome.

Changes of Address.

When notifying new addresses, members are requested to write them distinctly, and state whether they are temporary or permanent. Multiplication of addresses also to be avoided as tending to create confusion. In sending subscriptions, the use of the form attached to the application helps in the verification of addresses which the safe delivery of the Journal depends on.

- Bayly, Harold G., 1/o London; Moatside, Bedford.
Brach, Dr. L. K.; 223 Central Avenue, Norwich, Conn., U.S.A. (restored address).
Bradburn, J. A., 1/o Florida; 503, Willis Avenue, New York, U.S.A.
Davidson, Dr. Wm. B., 1/o Plumstead; City Gaa Works, Saltley, Birmingham.
Fairball, E. J.; all communications to 8, Scarborough Road, Stroud Green, N.
Golding, Jno.; all communications to Ashby Road, Kegworth, near Derby.
Heathcote, H. L.; Journals to Highlands, St. Nicholas Street, Coventry.
Highley, Arnold, 1/o Rochdale; Hawthorn View, 1st St. North, near Leeds.
Jacobs, Charles B., 1/o 19th Street; 52, Beaver Street, New York City, U.S.A.
Kenyon, Percy S.; all communications to Park Road, Cheddle Hulme, Cheshire.
Loomis, Henry M., 1/o West Chester; P.O. Box 85, Harrisburg, Pa., U.S.A.
McEwen, Atholl E., 1/o Lee; Box 6055, Johannesburg, Transvaal.

Meeting held on Wednesday, April 12th, 1905.

MR. EUSTACE CAREY IN THE CHAIR.

THE WOOD DISTILLATION INDUSTRY.

BY MAX MUSPRATT.

(this Journal, April 29th, 1905, pp. 372-374.)

DISCUSSION.

A. SMETHAM said the subject was of great importance to Wales and English agriculture; it had also been taken up by the Board of Agriculture. Whether the distillation of the waste lands of Great Britain could be made a profitable industry was still a matter of doubt, but there was no doubt that certain areas might be very profitably planted, and no doubt if some company could be formed to work on the lines Mr. Muspratt has suggested in some districts a profitable industry could be started. One of the great difficulties was that a very large proportion of the land called "waste" was useless alike for growing ordinary farm produce and for growing timber, the climatic conditions were such that it would be impossible to get anything like a crop of timber on any of the mountain sides in a period of 30 years. Suitable conditions 30 years was sufficient to get a profitable growth, but he did not think such a crop could be grown in that period in many parts of Wales, for example. With regard to the working, one of the great difficulties would be the getting of the timber in these remote places, and it fell to him that in many districts the cost of carrying the wood to the factory would be almost as great as the value of the products from the sources of supply in Wales or other great timber-growing countries. The land in England was far too circumscribed to allow a large area of the land for timber growing, and a greater area than 15s. an acre was required if the land was to be cultivated. The limit of profit suggested was too small to furnish anything like an adequate rent. It was a thing how, in some of the country places, land was sold at high prices for sheep running and so on. The Board of Agriculture had suggested more particularly in some areas which were used for water catching should be planted, which should be planted, and he was fully in agreement with that suggestion. It would have a beneficial effect in increasing the rainfall, and it would also have a beneficial effect, he thought, in the purification of the water from such areas. Unfortunately the difficulties of the areas at anything like reasonable rates seemed to be increasing greatly, and every Corporation—the London Corporation included—had to pay more and more for the areas from which the public got their water. It was possible that if they should realise even a moderate profit from the planting of timber in such areas it would be better than leaving them entirely unproductive, and to that extent he thought there would be a future and a considerable future for the planting of waste lands in Great Britain. But he was equally certain that any lands which could be profitably cultivated would never pay for the production of charcoal or even for the production of timber.

MR. ARTHUR CAREY asked how far the association was for advocating the afforestation of waste lands and approaching the Government, and with what object? A short time ago a statement was made in the House of Commons by Mr. Balfour, at which the question of afforestation was brought up. Mr. Balfour said it would be a very good thing. Under those circumstances he thought Mr. Carey had not the full facts before him. Mr. Muspratt, he estimates, put down the sum of 25s. per acre for the planting of timber. That appeared a very low estimate. What would be the value of felling timber would be used?

MR. HERBERT DAVIES said he was interested in a large estate in South Wales which was for the most part waste land. It was a very hilly country, unsuitable for agricultural purposes, and the proprietor many years ago planted a good deal of it with timber, but he found, as Mr. Smetham suggested, that, although he was near his market, the cost of haulage in this hilly district was so very great that almost the whole of the profit was absorbed in that one item alone, and with regard to the rent, the land, while unsuitable for agricultural purposes, was now getting a high rent for sporting purposes; but the timber part of it was a failure, although it was done on a large scale—5000 or 6000 acres. That one item, haulage, was so great as practically to destroy all profit on the timber.

MR. MUSPRATT said, with regard to the felling cost, the only definite figure he could get was from an Edinburgh expert who put the cost at 25s. The planting cost was £5 an acre. So far as the waste lands were concerned, the whole of that aspect of the subject first came into his mind in connection with the Vyrnwy watershed. He found that the Water Committee had been for some time past going in steadily for planting, without any ulterior object except that it was going to improve the catchment area, and he thought it was extremely desirable that if by any chance that could be systematised and this timber brought into profitable use that it would be an offset to some of the heavy expenses in connection with their water system. So far as rent was concerned in the case of lands owned by Government which were not really used, and especially as regards these watersheds, there was an opening for a satisfactory industry. Of course the distillation would have to be carried out on the spot. If the districts were hilly, especially such as at Vyrnwy, a certain portion of the hills on the side of the lake would be selected, and the timber would be allowed to come down upon slides into the water and be collected at the far end where the factory would be situated. That was also an expert question. He did not think the comparatively small quantity of timber in so large a body of water would affect the water. He felt that the subject was in its infancy as far as this country was concerned, and he hoped to get it thrashed out.

Meeting held at Burlington House, on Monday, March 6th, 1905.

MR. A. GORDON SALAMON IN THE CHAIR.

THE MECHANICS OF FIRE.

BY HENRY E. ARMSTRONG, PH.D., LL.D., F.R.S.

We are fireworshippers, both by inheritance and of necessity, sun-love being instinctive in mankind at large; and yet the sight of fire excites no wonder in most minds, such is the contempt bred of familiarity. At the present day, fire is the basis of all manufacturing industry in which motive power is a dominant factor—and as Niagara is but sparsely distributed must remain so to the end of time; nevertheless, we have scarce a thought for the morrow—scarce a pang of regret crosses our minds at the reflection that our fuel stores will be exhausted a few short centuries hence; the subject is dealt with almost in a flippant manner in the recent report of the Royal Commission on our Coal Supplies. We may well ask, therefore: "Is there no altruism in us that we calmly suffer the great wrong to posterity which is involved in the wicked waste of fuel now going on throughout the so-called civilised world?" The Atlantic liner is known to eat up coal at the rate of a ton every 2½ minutes as she voyages between New York and Hamburg; but no one thinks of the curses which pos-

terity will heap upon us if we take no steps to insure against a recurrence of the ice age—if we practice so little economy in the use of fuel. I must confess to feeling much sympathy myself with Professor Boyd Dawkins' contention that we should put a stop to the export of smokeless coal. To treat coal at all as a mere stone is a disgrace to our civilisation—we ought not to allow its exportation except in forms in which its energy-content is fully utilised. In pre-Joulian times there would have been some excuse for us—now, in view of the existence of a Society of Chemical Industry, it is impossible to plead even extenuating circumstances. But has this Society in its collective capacity, have its members individually, ever given proper consideration to the subject—have they ever thought of the transcendent importance of the study of fire and have they done anything to promote it? In referring to this subject, in my address to Section L, at the meeting of the British Association at Belfast in 1902, I said: "A scuttie full of coal excites no emotion in the literary mind: it should be one to call up harrowing visions, as well as a vista of memories extending far back into the ages of time—for in no other stone can we find a more wonderful sermon." Now, I may ask, "Does even a truck full of coal excite any emotion in the manufacturing mind—except through an account book?" I can conceive of no nobler purpose for this Society than that it should raise an insurance fund on behalf of fire, not against fire—for the scientific study of fire and its applications; so that Carlyle's words may no longer have any measure of truth: "From us, too, no chemistry, if it had not stupidity to help it, could hide that flame is a wonder."

Is not the present method of education such that chemistry has little but stupidity to help it? The discovery of fire—air—as Scheele most properly termed it—was the beginning of a new era in the history of the world. If we reflect on what has happened since: on the marvellous advance in knowledge which has accrued from the introduction of the experimental method; on the manner in which the use of science in the service of the world has increased our power and revolutionised our habits: we may well be struck dumb with wonder. But we should temper such wonder with amazement at the fact that instructors of our youth make no serious attempt to bring such knowledge properly before their pupils—no serious attempt to recognise the advent of a new discipline. Our children are in the hands of Goths! We hear of classical scholars reading Greek with feet on fender: if such could really see into the fire in front of them, they would realise that the vain imaginings of men in the past are as nothing in comparison with the wonders that we are beginning to see to-day in the world at large; they would set some value upon training truly calculated to cultivate the power of imagination and insight.

The question I have asked is an all-important one to consider. The state of chemical industry in this country would scarcely be so parlous as it is if our schools and universities had done their duty. The raw material of genius is abundantly at our disposal—yet we are even less regardful of it than we are of the energy content of coal. Ought not this Society, therefore, to take some definite share in promoting the immediate reform, root and branch, of our system of education? The journal it publishes is very valuable as a record of what other people are doing; but should not the Society display more directive and constructive activity? Is the lesson of Japanese success to be entirely wasted upon us—cannot we, too, show that we know how to organise victory?

I trust this prologue may not be entirely out of place: fire, it is well known, often leads to the blowing-off of steam.

In the present essay, it is proposed to deal mainly with fire as produced by oxidation of ordinary fuels; it should be pointed out, however, that the inquiry into the mechanics or true inwardness of fire cannot well be regarded as otherwise than co-extensive with that into oxidation phenomena generally, including those which attend vital changes.

My own initiation as an active fire-worshipper dates back to 1867, when I heard the late Sir Edward Frank-

land's wonderfully illustrated and entrancing lecture at the Royal Institution, (1) in which the insufficient flame was pointed out for the first time. I have listened to a more stimulating course. To me, a student, it was of infinite importance to hear doubt upon current belief and authority called in question; the display of solid grounds for such disbelief eminently inspiring. I would that every student attend a course of lectures on the ethics of disbelief.

I began to play with fire myself only in 1885, although I had formed views of my own about oxidation phenomena at least ten years previously. But my temerity was even in those youthful days, as I ventured to predict a mere mixture of hydrogen and oxygen—of these alone—would be found to be incombustible: (2) and has proved to be the case. Brereton Baker's achievement is, I suppose, known to all.

We have reason to be proud of the part which chemists have played in unravelling the mystery. The name of Davy, of course, comes first on the list; work such as Frankland, Dixon, Brereton Baker and have done is no unworthy sequel even to that of the Davy.

Dixon's memorable discovery of the incombustible carbon monoxide in the absence of water, which was announced in 1884, (3) must be regarded as the object of importance in the modern fire drama. Following this came H. B. Baker's epoch-making observations on the influence of moisture on the occurrence of chemical change, (4) which were crowned by his demonstration, in 1903, of the incombustibility of hydrogen, (5) even when wet, in the absence of oxygen calculated to render the water an electrolytic conductor. There remain to be mentioned the investigations carried out during recent years by Bone and his fellow-workers on the nature of the interchanges attending slow combustion in mixtures of hydrocarbons with insufficient oxygen for complete combustion; these are of great value as enabling us to trace the various stages of interchanges which precede complete combustion, in fact, the course of change. Twenty short years have brought marvellous additions to our knowledge; but the fruitful sources of error, the text books, are silent on matters and the work is appreciated here only within a narrow circle; it would seem that on the Continent European English is an unknown tongue: there is consolation in this, seeing that we are commonly not bad linguists.

Combustion of Hydrogen.

The study of fire may with advantage be begun by considering the formation of water from its elements; this will afford the opportunity of taking into account all that is fundamental in the occurrence of change in gases.

We are accustomed to talk glibly of oxygen combining with hydrogen to form water; but this is, of course, an imperfect, if not altogether misleading, statement of the actual course of events in a change which involves the formation of a molecule represented by the symbol H_2O from molecules such as those of hydrogen and oxygen, and are pictured to be by the symbols H_2 and O_2 .

The phenomena are undoubtedly electrolytic in character; indeed, no other interpretation can well be given. H. B. Baker's supremely important observation that a wet mixture, in equivalent quantities, of hydrogen and oxygen (so-called electrolytic gas) is inexplosive when taken to exclude acid impurity or such as may be from soft glass. (7)

It is commonly stated that water is the sole product of the fact that hydrogen peroxide is a constant end-product of the interaction is too often overlooked.

There seems to be little doubt that, as Trautmann argued, (8) hydrogen peroxide is never formed at low temperatures excepting as a product of the direct recombination of the oxygen molecule. It is not formed under conditions by oxidation of water, the interaction

not being reversible to any appreciable extent.

natures, as it is one which involves an endothermic of considerable magnitude. At high temperatures, however, it unquestionably is reversible; therefore reversibility must be entertained that hydrogen peroxide is a secondary and not a direct primary product of interaction of hydrogen and oxygen. The probability that such is the case is not great, however, if the hydrogen involved in the formation of water—if chemical changes generally—be regarded as electrolytic in character; and there would seem to be no other point open to us, since it is established that such changes take place when the conditions are those which give rise to the formation of a voltaic couple.

Electrolytic interchange can only take place in an electrolyte; therefore, conducting water, not water, is essential to the occurrence of the change and some between the hydrogen and the oxygen, which must respectively be subject to attack—the one by the positive other by its positive ion. According to the law, hydrogen peroxide cannot be otherwise than a product of the primary change. The importance of these deductions will be apparent later on. To arrive at a final conclusion as to the true inwardness of the process, it is necessary to consider fully the nature of the electrolytic change, although this may involve a somewhat lengthy digression from the main topic of discussion.

Nature of Electrolytic Changes.

Under this heading all changes may be included which involve the passage of a current—both those induced by the passage of a current derived from outside sources and those which involve the production of an electric current. Cases of electrolytic change may be distinguished: the first, that in which the ions of the electrolyte are discharged at and escape from the electrodes, these being called the "electrodes"; the second, that in which one or other ion of the "electrode"; the third, that in which both ions of the "electrodes." The second may be said to be of bipolar, the third one of bipolar depolarisation. Cases of chemical interchange may be reckoned either as cases of unipolar depolarisation or as cases of bipolar depolarisation; but it is doubtful whether even the case of electrolysis comes under case one, whether there be such a thing as a chemically inert electrode. In all cases, metallic and carbon electrodes are in some form of "chemical" attraction upon the electrolyte—it may well be this circumstance which gives them special value.* Those who have followed Sir James Dewar's wonderful experiments with liquid air at low temperatures must have been profoundly impressed by the attractive powers of this substance. (9) However, although the simplest conceivable case of electrolysis is apparently one in which a diatomic electrolyte is merely resolved into its ions A and B and these are discharged at and escape from the electrodes, such a case has no real existence; even the electrolysis of hydrogen chloride does not come within it, as the effective reaction must be supposed to be of greater complexity than is represented to be by the conventional formula.

For matters of convenience, electrolytic conductors may be divided into simple and composite electrolytes—the former class comprising those which are conductors of electricity (autolytes) (comp. Bousfield, W. R. and Lowry, Phil. Trans. R. Soc., 1904, 204, 256) and the latter mixtures of substances which act as conductors when associated with one another. But although the division is desirable—for purposes of classification in distinguishing those which will co-operate with their partners from those in which the co-operation is between themselves (e.g., acids with water)—it is not improbable that, in the process of electrolysis is essentially similar in all classes: the molecule of a simple electrolyte probably co-operates with another similar molecule much as the (heterolyte) molecules of solute and solvent co-operate in the case of composite electrolytes.

The influence of surfaces is not dealt with in this essay, a subject which has in no way received the attention it deserves to the extent to which they affect the rate, if not the nature, of gaseous interchanges has yet to be appreciated; there is little doubt that, in not a few cases, the changes supposed to take place in gases are in reality surface phenomena.

At bottom, the action of a solvent cannot well be otherwise than a chemical process in which both solvent and solute at all periods mutually affect each other. Generations of chemists have held this view and it is now again coming to the fore, if it be not already tacitly admitted by all (comp. Walden, *Deut. chem. Ges. Ber.*, 1905, 38, 345—409). But the original upholders of the ionic dissociation dogma have never yet had the courage to confess that, since the fundamental premises of their hypothesis that the solvent is inoperative except mechanically can no longer be sustained, the hypothesis is practically a dead letter.†

Any consideration of the nature of the process of solution must involve the discussion of that most difficult of all problems, the problem of valency, including that of its attribute residual affinity, an attribute ever present in the mind of the chemist but only recently recognised by the physicist under the guise of specific inductive capacity.

Of late years, precision has been given to our ideas by work such as that done by Pope on asymmetric sulphur and nitrogen compounds and by Collie and Tickle and others on oxonium salts. Although it is not proved that sulphur can act as a tetrad in the same sense that it acts as a dyad or that nitrogen can act as a pentad in the same sense that it acts as a triad, we cannot do otherwise than grant that radicals from the added compound become separately combined with the sulphur and nitrogen in the formation of sulphonium and ammonium compounds. Whether this be true of the oxonium compounds is open to question; at present there is no evidence which compels us to assert that such is the case. To take a concrete example, it is to be supposed that when hydrogen chloride dissolves in water, a compound of the two molecules is formed. Assuming that a molecule of each is concerned, the compound may be represented in two ways—

For the purposes of the present argument, it matters little whether the one or the other formula be adopted. Such molecules would be in a state of unstable equilibrium: in consequence of the association of the chlorine with the oxygen, these elements would have less hold upon the hydrogen than they had when they enjoyed its possession undisturbed, so that the chlorine, if not the oxygen, would be more attractive of other elements. What is termed ionisation may be regarded as a consequence of the formation of such complexes: in the case of a compound like hydrogen chloride, which is said to be almost completely "ionised" in solution, action may be supposed to take place almost entirely in the forward direction.

But "ionisation," on this hypothesis, is a state of readiness to travel—not a state of actual travel; and co-efficients of ionisation are co-efficients of potential activity not of suicidal mortality.

It remains to consider the part which such complexes (composite electrolytes) may be assumed to play in chemical interchanges. As special attention has been drawn by Traube (8) to the formation of hydrogen peroxide from zinc, water and oxygen, it will be desirable to discuss the behaviour of this metal towards "water" and acids.

† Fortunately, there are signs that the strange hypothesis that electrolytes are compounds gifted with suicidal mania is losing its popular hold and there is hope that ere long the dogma that the ions pursue a lonely existence in the watery wastes of solution will no longer be taught to condoling youth as gospel but will figure only as a convenient mathematical fiction: the conception being one which runs counter to the feeling which surely is innate in all of us—that nature governs by attraction and affection—and which forbids us to believe that she revels in disruption. It is of no slight importance to the progress of our science that we recover sanity of judgment and become chemists once more, especially that we again seek to develop the technique which distinguished the older workers. Highly as we must value the aid which mathematicians and physicists have rendered of late years in extending our methods of inquiry, it is none the less a mistake to allow those to legislate for us who have but a distant acquaintance with our subject matter and who necessarily, therefore, lack that fine sense of sympathy and instinct which only intimate knowledge bred of constant intercourse can give.

first. By hypothesis, zinc cannot act on water pure and simple; some "impurity" must be present to condition change; ordinarily the interaction may be pictured as taking place in the following manner between the metal coupled with an electronegative conductor and water in presence of a minute amount of acid impurity (HX):

Directly or indirectly, the zinc hydroxy salt thus produced is converted by the action of water into zinc hydroxide and the acid HX. The cycle is then repeated, so that gradually the zinc is more and more attacked, although, owing to the very high resistance of the electrolyte, action proceeds very slowly. As the amount of acid present is increased, there is more and more opportunity for change to occur and action proceeds far more rapidly; moreover, the hydroxy-salt is then converted into the salt of the acid used. In early days, the formation of the salt was explained by assuming that the metal was oxidised at the expense of water and that the oxide so produced combined with what is now spoken of as the acid-forming oxide or anhydride, which formerly figured as the acid; latterly it has been assumed that the metal displaces the hydrogen of the acid. The view stated above may be said to be a compromise between these two explanations and to include both.

As zinc has a heat of oxidation higher than that of hydrogen, there is no reason to suppose that oxygen intervenes—as it must in the case of a metal such as copper, for example, if dissolution take place. The formation of hydrogen peroxide from zinc and "water" is therefore to be ascribed to a secondary change—to oxygen depolarisation at the negative conductor.

Although Traube found that but little hydrogen peroxide was to be detected when "water" alone acted on zinc, by substituting lime water for water, he was successful in obtaining an amount almost corresponding to that indicated by the equation $\text{Zn} + \text{OH}_2 + \text{O}_2 = \text{ZnO} + \text{H}_2\text{O}_2$, conditions being then secured which made the survival of the peroxide possible. (8) It may be pointed out that when a metal such as zinc is dissolved in presence of oxygen the amount of peroxide formed must depend entirely on the extent to which the negative conductor becomes coated or plated with oxygen; slow dissolution and constant agitation must therefore promote its formation; when action is rapid and hydrogen is evolved in considerable quantity, the presence of oxygen at the negative electrode surface is practically precluded. On the other hand, it is to be supposed that the formation of hydrogen peroxide is a necessary part of the change in those cases in which the oxidisable substance has a heat of oxidation below that of hydrogen; there can be no output of energy unless it be formed.

To apply what has been said to the formation of water. The oxidation of hydrogen may be regarded as typical of all those cases in which no change can take place unless there be oxygen depolarisation. The manner in which it may be supposed to take place is shown in the equation:

In so far as it escapes decomposition by heat, it may be supposed that the hydrogen peroxide which is formed initially—by direct reduction of the oxygen molecule—itsself acts as depolariser; so that eventually the whole oxygen molecule is effective, although its utilisation takes place in two stages.

This represented, the formation of water by combustion of hydrogen is obviously a process of *hydroxylation*. Probably this is true of all oxidations; as will be apparent later on, there is the clearest evidence in the case of the hydrocarbons that hydroxy-derivatives are first produced.

The strongest argument, perhaps, in favour of the view here put forward is that afforded by H. B. Dixon's remarkable observations on the influence of excess of hydrogen and of excess of oxygen on the rate of propagation of the explosive wave. (10) His results are embodied in

the following table; they are, in part, expressed graphically in Fig. 1. It will be seen that while excess of hydrogen promotes combustion, excess of oxygen retards the rate of change; a somewhat paradoxical result at first sight.

TABLE I.

4H ₂ : 1O ₂	3532	H ₂ : 1O ₂ + 1N ₂	2421
3H ₂ : 1O ₂	3527	H ₂ : 1O ₂ + 1N ₂	2051

H ₂ : 3O ₂	1707		
H ₂ : 4O ₂	1281		

FIG. 1.

But this influence of oxygen meets with an explanation when it is borne in mind that whereas the stability of molecules of water, of hydrogen and of oxygen diminishes as temperature rises, the stability of hydrogen peroxide increases, being at a maximum at some relatively elevated temperature which has not yet been determined. There can be no doubt, in fact, that water is directly oxidisable at high temperatures; consequently, oxygen and water hold one another in check; each either must tend to retard combustion. Excess of hydrogen on the other hand, should promote combustion, not because it is present in more than the equivalent proportion and because it diminishes the proportion of hydrogen peroxide by promoting its dissociation. (11)

All that has been said above is simply expressed by representing the interchanges as reversible.

Combustion of Hydrocarbons.

It is necessary to discuss the combustion of hydrocarbons next to that of hydrogen, before considering that of carbon monoxide and of carbon, as the interpretation of the behaviour of these latter is only possible when that of the former is understood.

Of late years, much has been said as to which is the more combustible constituent of hydrocarbons, the hydrogen or the carbon. Faraday, in discussing the chemistry of the candle flame, told his young hearers that the forces which hold the two elements together are so nicely balanced that the hydrogen is made to come first, the carbon afterwards; and in view of the tenacity of hydrocarbon flames to smoke, such a conclusion may well seem to be natural if not necessary. But, as points out (10, p. 160), the fact that hydrogen is separated when hydrocarbons are exploded with insufficient oxygen led Karsten, in 1861, to formulate the conclusion before any portion of hydrogen is burnt all the hydrogen is burnt to carbonic oxide and that then the excess of oxygen divides itself between the carbonic oxide and hydrogen. Thirty years later, Smithells became a strenuous advocate of this doctrine, going so far as to say (12) that "The view that carbon is separated from a flame owing to the preferential combination of oxygen with hydrogen is opposed, the author thinks, to all evidence."

evidence, which he is of opinion goes to show that the oxygen supply be limited, carbon will burn without hydrogen." In a correspondence which passed on Sir G. Stokes and myself early in 1892, I endeavored to demur to such an interpretation; at the close of my letter, I said: (13).

Regarding the interactions in flames as consisting of a series of simultaneous and consecutive explosions, which we can only examine the final steady state, it is to me that the phenomena are necessarily of an extremely complex character and that their appreciation and successful interpretation must tax our powers of analysis in a very high degree. It will certainly also at present to infer that either the oxidation of hydrocarbons or the separation of carbon and also hydrogen from them takes place entirely in any one

interpretation was somewhat scoffed at by a chemist in the discussion; but time has brought its reproof. The recent work of Dr. Bone and his associates has, I think, entirely justified my conservative view. In the course of a brilliant series of investigations on the incomplete combustion of hydrocarbons at various temperatures, these chemists have shown that carbon is gradually introduced into the hydrocarbon as precisely as it is when wet oxidising agents are used, so that, in principle, there is no distinction to be made between slow combustion and high temperature combustion. From the outset I was inclined to the view which I was the first to express in a paper, I believe, as far back as 1874, in my "Introduction to the Study of Organic Chemistry" (Longman's). In reality, oxidation is always a process of hydration (14) which takes place under the conjoint action of water and oxygen, e.g. :—

Methanol Methanediol Methanetriol Methanetetrol

In their earlier experiments, Bone and Wheeler failed in obtaining evidence only of the production of aldehyde: $\text{CH}_2\text{O} = \text{CH}_2(\text{OH})_2 - \text{OH}_2$. Therefore, it is possible to represent the interaction as one in which a hydrogen molecule, as it were, slipped into the hydrocarbon molecule, thus:—

Subsequently when it was found that ethane may be oxidized to ethylic alcohol, all doubt was removed as to the validity of my argument that the interaction is in every way comparable with that involved in the formation of water from hydrogen; thus:—

Seeing that the process is one involving hydroxylation, it would seem that the hydrogen of the hydrocarbon is not stacked. But if mere appearances be not allowed to deceive, looking below the surface, we may, I think, anticipate the prior attachment of oxygen both to the carbon of the hydrocarbon and to the oxygen of water; and in large measure only taking place within complex systems constituted. If so, both parties to the discussion will consider that they carry their arms honourably in action—both had faint glimmerings of the truth. In Bone and Wheeler's observations became clear, at once the scales fell from our eyes: it was clear that the formation of carbon monoxide and of hydrogen by the previous observers had regarded as proof of the low affinity of carbon for oxygen (15)—was due to the position by heat of primary educts; that, in fact, the *thermoschists*, not direct products of oxidation, acetaldehyde giving rise first to formaldehyde and then carbon monoxide and hydrogen:—

methanetriol to formic acid and then to carbon monoxide and water:—

Proceeding a stage higher in the paraffin series, the behaviour of ethane is at first similar to that of methane. Owing to the fact that ethylic alcohol is more readily oxidised than ethane, the action cannot well be arrested at the first stage. But Bone and Stockings have had no difficulty in showing that acetaldehyde is produced; the relation of this compound to ethanediol is, of course, of the simplest:—

As combustion proceeds, the acetaldehyde is in part resolved into the simple *thermoschists*, methane and carbon monoxide; in part, it is further oxidised, probably to glycolic aldehyde, $\text{CH}_2(\text{OH}) \cdot \text{COH}$, which then breaks down into formaldehyde. At an early stage, therefore, the ethane is resolved into derivatives of methane.

The behaviour of more complex hydrocarbons than ethane, whether of the paraffin or other series—of hydrocarbons generally, in fact—is doubtless similar to that of ethane. But, judging from observations such as those made by Thorpe and Young on the decomposition of paraffin wax by distillation under pressure and by Miller and myself on the products of the manufacture of oil gas, (16), there is little doubt that, as a rule, when combustion is once started, the more complex hydrocarbons are resolved in the wave front into simple hydrocarbon molecules prior to oxidation; in the case of benzenoid hydrocarbons, such thermal decompositions probably only set in when oxidation has taken place to some extent.

The intolerable alliaceous stench emitted by the oil motor of to-day is undoubtedly traceable in part, if not entirely, to the presence of such "cracked" hydrocarbons in the escaping gas; the odour being that characteristic of "oil gas," which is well-known to be largely due to certain unsaturated hydrocarbons of the $\text{C}_n\text{H}_{2n-2}$ or acetylene series. It would seem to be the rule that, when heated, all paraffins are more or less readily resolved into a paraffin containing half the number of carbon atoms present in the original hydrocarbon and the corresponding olefine:

The olefines, in like manner, are converted into a lower paraffin and the corresponding acetylene:

Carbon is separated when this process is carried to the bitter end. It should be noted, however, that this separation is not a simple process of decomposition but one involving the formation of an exceptionally complex molecule (C_n) from its simple components.

It was argued originally that the carbon in hydrocarbons must be supposed to undergo combustion in preference to the hydrogen, because when either acetylene or ethylene is exploded with its own volume of oxygen only carbon monoxide and hydrogen are produced, no carbon being deposited:

From this point of view, ethane should also give carbon monoxide and a larger proportion of hydrogen:

Dr. Bone has been good enough to inform me that such is not the case but that when the mixture of ethane and oxygen is exploded in a sealed glass bulb a lurid flame fills the bulb; in fact, much carbon separates, the volume increasing only to slightly less than two and a half times that of the original mixture. This result is complete disproof of the hypothesis that the carbon burns preferentially, especially when the character of the products is considered. But very little carbon dioxide (about 4 per cent.) is formed: the chief gaseous products are carbon monoxide (about 35.5 per cent.) and hydrogen

(45–49 per cent.); there are present besides these, however, not only ethylene and acetylene (3–4 per cent.) but also a not inconsiderable proportion of methane (10–11 per cent.). Dr. Bone tells me that about 15 per cent. of the carbon of the ethane was separated as such during the explosion, about 25 per cent. of the hydrogen appearing as steam. On washing out the tubes with water, after the explosion, a solution was obtained in which aldehyde was easily detected. These results are readily understood if it be supposed that the ethane is first converted into acetaldehyde, which then decomposes into carbon monoxide and methane; and that, in turn, this latter is partially resolved into carbon and hydrogen:

When a mixture of equal volumes of ethylene and oxygen is exploded, neither does carbon separate nor is steam formed; the end products are simply carbon monoxide and hydrogen:

Dr. Bone has made experiments on the thermal decomposition of acetaldehyde and formaldehyde which have afforded results entirely confirmatory of these arguments.

If acetylene be oxidised in contact with its own volume of oxygen, it affords both carbon monoxide and formaldehyde when the combination is effected below the ignition point; but above the ignition point, only carbon monoxide and hydrogen are obtained. The separation of carbon when it is burnt in the air must be regarded as due to its decomposition by heat—not to the preferential combustion of the hydrogen. There can be little doubt, in fact, that Davy expressed a correct opinion in saying, in 1818, that—

"Flame must be considered as the combustion of an explosive mixture of inflammable gas or vapour and air, for it cannot be regarded as a mere combustion at the surface of contact of the inflammable matter..."

Combustion of Carbon Monoxide.

Of all known combustibles, carbon monoxide is apparently the most paradoxical in its behaviour: it is the most thirsty among gases, the explosive wave travelling at the maximum rate in a moist mixture of carbon monoxide and oxygen only when a large proportion of water is present. The influence of water is fully displayed in the following table and in Fig. 2.

TABLE 2.

Condition.	Per Cent. of Steam Present.	Mean Rate in Metres per Second.

" 65° C.	24.9	1.526
" 75° C.	38.4	1.266

FIG. 2.

It is noteworthy that the addition of steam to dry gaseous mixtures does not increase but some diminishes the rate of explosion.

If the explanation that has been given of the manner in which methane undergoes combustion be accepted from being exceptional, this behaviour of carbon monoxide is precisely that which is to be expected. Granting carbon monoxide is not a direct produce of combustion but a mere thermosehist formed by the resolution of primary products such as methanediol and methaneol, its oxidation must be preceded by its reconversion to formic acid:

Since this change occurs only to a relatively small extent owing to the instability of formic acid at high temperatures, it must take place up to a certain point with increased readiness as the proportion of water is increased—steam may be added, if the pressure be increased, as high pressure will promote the formation of formic acid and also favour its persistence. The constant appearance of carbon monoxide in relatively large amount among the products of incomplete combustion is readily explicable from this point of view, especially in cases in which little or no steam is present—as, for example, on exploding a mixture of cyanogen and oxygen. (17)

The results obtained on exploding cyanogen, methane, and ethylene with various proportions of oxygen and nitrogen are given in Tables 3, 4 and 5 and in Figs. 1 and 3.

FIG. 3.

Combustion of Carbon.

Carbon, it must be remembered, is misrepresented by the symbol C. Actually, expressions such as C_xy , etc., in which x and y are high unknown values, should be used for its varied forms. Each element in the carbon complexes may be thought of as undergoing oxidation separately (14) in a circuit comprising the composite electrolyte and oxygen; the size

which is eventually obtained may be regarded as a product of later changes. At this point of view, the readiness with which and extent to which the dioxide is formed on burning must depend on the amount of water present. Following results obtained by H. B. Baker, in 1885, series of comparative experiments in which carbon was heated both in moist and in dried oxygen (*) are given from this point of view:—

Wet.	Dried. 1 week.	Wet.	Dried. 2 weeks.	Wet.	Dried. 4 weeks.	Wet.	Dried. 8 weeks.	Wet.	Dried. 12 weeks.	Wet.	Dried. 16 weeks.
50.1	15.4	51.0	19.0	45.3	14.1	23.3	12.5	58.8	15.8	52.4	17.8
22.2	20.6	31.2	14.8	32.5	27.8	60.0	27.5	23.2	24.2	25.2	16.5
—	41.3	—	46.1	—	28.2	—	39.0	—	33.3	—	45.0
27.6	22.6	17.7	20.0	22.1	29.8	16.6	21.0	17.9	26.6	22.3	26.6

only definite evidence at present available as to the nature of the carbon complex, to which reference is made above, is that afforded by the production of mellitic or benzenehexacarboxylic acid, $C_6(COOH)_6$, on oxidation of charcoal. (18) The formation of such an acid may be regarded as proof of the existence in the molecule of at least one C_6 benzene (phenic) nucleus. In the mind the marked tendency of carbon atoms to group in sixes—revealed in the formation of benzene and benzenoid hydrocarbons at high temperatures—also be postulated as probable that the carboxyl groups in the mellitic acid are severally formed by the breaking down of C_6 groups in the charcoal, much in the way that phthalic or benzenedicarboxylic acid is formed from naphthalene or diphenic:

assuming that a tetraphene complex is fundamental to the carbon molecule, to account for the absence of oxygen it must be further supposed that at least two systems are superposed or united; on such an assumption, the molecule of amorphous carbon would contain at least 36 atoms. When benzenoid hydrocarbons undergo combustion, apparently the complex breaks down into simpler molecules, at an early stage, when oxidation takes place only partially—as in the case of the paraffins, etc.; it is at least probable that similar modifications set in when the complex carbon molecule is oxidised. It is obvious that all such conclusions are mere speculations—nevertheless they rest on a substantial basis of fact.

Retardation of Combustion by Oxygen.

In discussing the combustion of hydrogen, it has already been pointed out that oxygen, when used in excess, is more effective than any other diluent in retarding the reaction. Dixon has shown that it is an active diluent in other cases of explosive combustion; and similar observations have been made by Bone and his fellow-workers in the course of their experiments on low temperature combustion. Dixon's values for cyanogen, methane, ethylene are given in tables 3 to 5. It will be seen that the damping effect of nitrogen but very slightly exceeds that of oxygen in the case of the hydrocarbons.

The different influence exercised by oxygen when water is present in excess is well brought out on contrasting curves representing the behaviour of carbon monoxide and of cyanogen (Fig. 1) with those representing that of the hydrocarbons (Fig. 3): in the latter the influence rises to a maximum and then falls

In the case of gases such as carbon monoxide and cyanogen, it is not difficult to understand that oxygen should exercise such a damping effect, if, as suggested, it enters into combination with water at high temperature to form hydrogen peroxide, thus withdrawing water from the sphere of action. But in the case of hydrogen and hydrocarbons such an explanation is scarcely sufficient, as the amount of water present from the moment that these gases begin to undergo combustion must be far in excess of the amount requisite to secure the maximum rate of change; in such cases oxygen must itself be held back by combination with water. But this explanation that oxygen may be held back in the form of hydrogen peroxide by water involves the important conclusion that oxygen itself,

not hydrogen peroxide, is the effective depolariser in combustions—in other words, that hydrogen peroxide does not operate, at all events to any great extent, as depolariser in changes at high temperatures. Surprising as this conclusion may appear to be at first sight, it is less so when it is borne in mind that whilst the stability of the oxygen molecule diminishes, the affinity of water for oxygen—and, therefore, the stability of hydrogen peroxide—is at a maximum at high temperatures. When electrolytic gas is mixed either with oxygen or with nitrogen or with steam, oxygen has most effect and steam least in retarding combustion; it is not surprising that this should be the case, as steam is the one substance which increases as combustion proceeds and is the least likely, therefore, to influence the process.

Autoxidation—The formation of peroxides and of ozone.

As already pointed out, the inquiry into the mechanics of fire cannot well be regarded as otherwise than co-extensive with that into oxidation phenomena generally. It will therefore be desirable to indicate briefly the bearing of the main argument put forward in this communication on the interpretation of the class of phenomena termed autoxidations, in which change takes place automatically under the influence of ordinary molecular oxygen. It is recognised that a peroxide is always produced, although its existence may be ephemeral. Engler and Weissberg, who have fully discussed the subject in their monograph, "Kritische Studien über die Vorgänge der Autoxydation" (Vieweg und Sohn, Braunschweig, 1904), contend, however, that two kinds of autoxidation are to be distinguished: in the one, molecular oxygen unites with hydrogen, forming hydrogen peroxide, as in the case of the oxidation of zinc; in the other, the autoxidisable substance is directly peroxidised, hydrogen peroxide being formed from the peroxide by a secondary process—by the action of water. The oxidation of turpentine is supposed to be a case of this latter kind.

It may be pointed out that there is no need at present to assume that oxygen ever acts otherwise than as molecular oxygen; not the slightest proof has yet been given that even so-called nascent oxygen is atomic or ionic oxygen—that it is other than oxygen in actual circuit with the oxidisable material. If it be granted that an electrolyte intervenes in all cases of chemical change, the direct oxidation of any substance becomes an impossibility. Therefore, when conducting water is the electrolyte, molecular oxygen, O_2 , must in all cases give rise primarily to hydrogen peroxide, if the general equation of oxidation be—

It will be said that in several of the cases studied, water was not present. I venture to think, however,

DISCUSSION.

H. BRERETON BAKER said he was carrying out experiments on combustion in order to determine moisture had such an important influence—why substances would not burn if they were dry. He it go quite so far as Dr. Armstrong in the matter ory; he did not feel that he could admit that ionic ation could be consigned to the limbo of lost ss. The possibility of the different polarities of oxygen, which Brodie imagined some 40 years ago, was present in his mind. The oxygen may be supposed to break up into two oxygen ions when an electrolyte is present. He went with Dr. Armstrong inasmuch as he had proved that the presence of an electrolyte was necessary for ionic action. If it were not for that theory, which he referred to over and over again, he was quite sure that fully half of his own work would not have been done. He tried some experiments about two years ago, if a very dry gas had a smaller volume than a gas which was merely passed over phosphorus pentoxide. The degree of dryness would not stop chemical action, the gas were left in contact with the phosphorus pentoxide for a few days, it made all the difference between going on and stopping. He tried to find out whether there was any contraction when ordinary dry gas was made as dry as possible, and he had an opportunity to do so delicate that it would detect a contraction of 1/1000th of the volume by direct measurement. He spent some six months drying to see if any contraction took place. If there had been any contraction he would have considered it was proof of dissociation of the gas; he was disappointed when he found no contraction took place. But he did not conclude that disproved the ionic explanation at all, and his appointment came to an end in talking over the matter with Prof. Townsend, who told him there were 14 ions present in a litre. Some members would, however, remember how many billions of molecules were in a litre of oxygen, but, at all events, what was to be measured was, not one part in 7,000, but 14 in many billions, and it did not seem possible to measure it by direct measurement. The experiments now making were to ascertain if the presence of ions could be determined by an indirect method. If a gas was very dry, it did not allow an electric current to pass through it, and that looked like ionisation. He took three similar bits of glowing phosphorus, placed them in lead tubes, and over them a photographic plate was placed. He wanted to measure the amount of light given out by these pieces of glowing phosphorus. One was charged positively from a large accumulator; the second was charged negatively, and the third was left uncharged. The phosphorus was just moist enough to make it a conductor. He left it about half an hour and developed the plates; under the positive tube was a black mark; under the negative scarcely any; the third was about the mean of the other two. This was only one experiment, and many more would be done to confirm the observation. It seemed to him that the experiment, which of course required confirmation, would throw some light on the question as to whether ions were really produced, the positive ions of oxygen attracted to one side, and the negative ions to the other. There were very few positive ions combining with the phosphorus; what became of them? They were taken up when phosphorus glowed ozone was produced. He did not measure the ozone coming from a piece of phosphorus, but if the hypotheses were correct, he would find little ozone at the positive end, whilst much would be produced at the negative end.

E. DIVERS said that if it were always borne in mind, it should be, that molecular quantities are, according to the fundamental theory of chemistry, those proportions in which substances chemically interact, there would be no hesitation in admitting that the product of the union of oxygen with hydrogen must be hydrogen peroxide, the formation of water resulting from the union of hydrogen with its molecular equivalent of hydrogen. The valuable and beautiful experiments made by Dr. Bone

and his fellow-workers upon the oxidation of hydrocarbon gases, owed very much of their interest to the fact that they had served to demonstrate the apparently inevitable error of regarding a chemical compound as a mixture of its elements. Thus, in the combustion of methane, there could not properly be asked the question, whether its carbon oxidises before or after its hydrogen, since there is neither carbon nor hydrogen present to be oxidised, but only the homogeneous substance, methane. He had had the opportunity of pressing this fact upon the attention of Dr. Bone, on the occasion of the reading of his first paper on the subject, and the evidence afforded by subsequent papers by Dr. Bone and his colleagues had been fully in accordance with it. Water and the oxides of carbon are products of the break-up of oxidised hydrocarbons, not products of the oxidation of hydrogen and carbon.

MR. DAVID HOWARD said that, speaking from the point of view of a manufacturing chemist who used large quantities of fuel, the question was, where did all the calories go to? How was the tremendous loss to be set right? This could only be done by realising the great complexity and difficulty of so simple a thing as burning coal. It was by following up this question thoroughly and with the aid of modern methods of investigation, that economies in the consumption of fuel could be effected,

DR. H. G. COLMAN congratulated Prof. Armstrong on the manner in which his suggestion of 20 years ago, that combustion always took place through hydroxylation had been confirmed by the results of Dr. Bone and his fellow workers. They were all agreed that so far as that portion of the work was concerned, the evidence was very strong, that the position maintained by Prof. Armstrong was correct. But he must say he did not feel quite convinced of the correctness of Prof. Armstrong's view as to mechanism of the reaction by which the oxygen was introduced between the carbon and the hydrogen. He felt, with Dr. Brereton Baker, that the evidence at present was not sufficient to convince them that that really took place in the manner suggested. At the same time, one could not advance without making hypotheses, and even if this did not prove in the end to be altogether correct, it would probably prove to contain at least a portion of the truth. With regard to the combustion of cyanogen and oxygen, he did not quite understand what explanation the author gave of the formation of CO from a mixture of cyanogen and oxygen, even where it was dried as far as possible. He rather gathered that he would say, that in reality this mixture was not absolutely dry, but only dried so far as their means enabled them, and still contained some moisture. Further, speaking of carbon, Prof. Armstrong said that many people attributed to it, without thinking, a much simpler constitution than it really possessed, whereas the carbon molecule had in reality a very complex constitution. He was inclined to go further, and doubt whether there was such a thing as elementary amorphous carbon; whether they had not really to deal, in the case of amorphous carbon, with a very condensed hydrocarbon, or rather a mixture of hydrocarbons, in which the number of atoms of carbon was so great and of hydrogen so small that practically the hydrogen was hardly detectable.

DR. C. A. KOHN said that to anyone connected with the problem of oxidation, this discourse had been one of exceptional interest, and Dr. Armstrong had shown how much was left out, and how little was indicated, by the ordinary equations employed in expressing simple oxidations like that of hydrogen. The intermediate formation of hydrogen peroxide was proved by many simple experiments, and it was in connection with this initial change that Dr. Armstrong had put a new view before them, the necessity of an electrolytic medium. It was not very evident how far this intermediary helped one in following up the changes which were capable of being fairly well understood without it. In the case of hydrogen itself, there was perhaps less field for argument, but in that of autoxidation such an hypothesis did not appear to be called for as far as experimental work had gone at present. Where one was concerned with organic substances of the type of benzaldehyde, it had been shown

by Baeyer and Villiger that oxidation proceeded through the addition of molecular oxygen to the oxidised compound, from which benzoic acid subsequently resulted. He should like to ask Prof. Armstrong if, in these cases, he also introduced this intermediate electrolyte, namely, a small portion of hydrochloric acid in association with water. As regards the action of water itself, experimenters differed as to whether it was necessary to such oxidation or not; Jorissen and Nef came to opposite conclusions in the case of benzaldehyde. For his own part, he had experimented in this direction, and was not able to prepare any benzaldehyde which did not oxidise on exposure to dry air. It seemed undoubtedly that moisture was required for the oxidation, but whether it was necessary to introduce hydrochloric acid with the water was a point on which further evidence must be awaited.

Mr. R. J. FRISWELL said he was interested in the communication referred to by Prof. Armstrong from Dr. Bone, who stated that when he burnt certain hydrocarbons containing a relatively large amount of carbon, carbonic oxide, hydrogen and 15 per cent. of carbon were obtained.

Some years ago he investigated the manufacture of lamp black, or vegetable black, as it is termed, from the "green oil" obtained from gas works. Roughly there was in the hydrocarbon mentioned by Prof. Armstrong, as used by Dr. Bone, a body containing about 75 per cent. of carbon and 25 per cent. hydrogen. In these "green oils" the percentage of carbon was higher. The oils flowed in a small stream on to a plate and were burned with a limited amount of air. Curiously enough the percentage of carbon obtained from them was extremely close to the one mentioned by Dr. Bone as obtained in his accurate experiments: the carbon being from 15 to 17 per cent. of the total weight of oils burned. There was no doubt in his mind that there was among the other products of combustion carbon monoxide in considerable quantities.

Another point was the introduction of hydroxyl groups by oxidation at low temperatures, and in this connection he would refer them to some work he had published on the action of weak nitric acid on coal. By reducing the products so formed with zinc dust he was able to introduce a large number of hydroxyl groups into the coal. The coal had thus been made to revert towards the state in which it had previously existed as an imperfect or peat-like coal.

The question of the utilisation of fuel was, of course, one of enormous importance and immense complexity, and he felt sure a great stimulus would be given by the study of this question.

Prof. H. E. ARMSTRONG, in reply to Dr. Colman's question with reference to the combustion of cyanogen, said that in that case the drying could be carried very much further than it could be in the case of carbon monoxide without stopping the combustion: a very small amount of water would be sufficient, he thought, to initiate its conversion into carbon monoxide. In a paper communicated to the Chemical Society some months ago he had given a scheme indicating a way in which he thought the explosion of cyanogen might be explained. Dr. Koln had referred to the way in which benzaldehyde and similar compounds underwent autoxidation. This was a rather complicated and difficult subject to discuss: but, stated briefly, his opinion was that in such cases they must imagine a mechanism very similar to that which he had suggested should be thought of as playing the active part in ordinary combustion phenomena. He did not think they could accept the idea that the organic peroxide was a primary product any more than they could accept the idea that the hydrogen peroxide was a primary product in cases of oxidation such as that of hydrogen and those he had discussed that evening. He was quite prepared to admit, however, that there was a good deal of room even now for difference of opinion. What he desired to urge was that there should be some clear idea before them of what might be supposed to happen, so that they should be able to discuss these matters at all events from a common platform.

The difficulty which others had in putting themselves into what he might call a rational position in considering such questions was very surprising; he did not know how it arose, and never could quite understand the hesitation. But it was evident that men who had worked much on the subject—Prof. Dixon and others—had the greatest difficulty in seeing their way through explanation of the kind which he had offered. It seemed to be so thoroughly saturated with facts and so thoroughly got into the habit of reading their objections directly, instead of considering what might be behind them, that it was very difficult for them to suppose there was a complex machinery at work such as he pictured.

Manchester Section.

Meeting held at Manchester, on Friday, April 7th, 1906.

MR. J. CARTER BELL IN THE CHAIR.

A REGULATING VALVE FOR CONTROLLING THE ADMISSION OF STEAM TO VITRIOL CHAMBERS.

BY W. H. COLEMAN.

Everyone who has had to control the working of a set of vitriol chambers will agree that the proper regulation of the steam supply is of the utmost importance.

The average tower man, when questioned will frequently reply that he has put on or taken off "just a breath" or "a half" or "a quarter of a turn" of the valve. This answer leaves some doubt in one's mind as to what exactly has been done. In order to obviate this difficulty by an attempt to gain a better method, and to try to obtain a means of knowing the history of the steam supply to a chamber during some time previous to any alteration the author has devised the valve shown, and he hopes that the matter is not too trifling to be worthy of your attention.

The valve, which is of the ordinary screw-down pattern,

toothed wheel formed on the spindle which engages another wheel of greater diameter working on a port attached to the body of the valve. The face of larger wheel has been divided and numbered. When valve is closed the pointer indicates the figure 0 on scale, and when fully opened it indicates for this valve 16.

On steam, after being reduced to any suitable pressure the type of reducing valve, is adjusted by means of an indicating valve, and one can tell at a glance how it is open.

A board or slate is hung up by the side of the valve and the man writes down the time, steam pressure and other figure every time that he makes an alteration in steam supply. In this way, the history of the steaming of the few preceding hours is always at hand, and if the supply require alteration, it is easy to determine how much or how little that alteration should be.

SUSPENDED MATTER IN SEWAGE AND EFFLUENTS.

BY GILBERT JOHN FOWLER, D.SC., AND EDWARD ARDERN, M.Sc.

It is becoming more and more generally recognised that the real difficulty in the problem of sewage purification is, not so much in producing a good effluent, as in getting a satisfactory method of dealing with sludge. It is a thorough understanding of this problem that is necessary to know the character of the suspended matter at different stages of the purification process, *viz.*, in the sewage, in the tank-effluent, and in the filtered effluent.

Suspended matters in Sewage.

Sewage may be classified as follows:—

- (i.) Floating material and detritus.
- (ii.) Finely disseminated solids
- (iii.) Matter in emulsion or colloidal matter.

Inference may be made to the experiments which have been made in Berlin by Dr. Monti* of passing sewage through a series of fine sieves.

(I.) Floating Material and Detritus.

The character of the above varies in different towns requiring necessary a modification in methods of screening. In Manchester, owing to the large quantity of cotton rags, &c., it is advisable to screen the sewage as it enters the works, whereas at Birmingham, it is possible, instead of screening the whole of the sewage, to simply screen the sludge. Included under the head of floating matters, there will, of course, be quantities of solid faeces, &c., vegetable debris, &c.

The following is the result of examination of an average load of detritus removed from the screening chamber at Manchester. It consists of a large proportion of sand and fine material, a fair amount of coal, also of stones, &c., small pieces of brick, wood, paper, leaves, &c. Analysis of dry matter:

Loss on ignition, 34.9 per cent.
Mineral matter, 65.1 per cent.
Fine material (less than $\frac{1}{16}$ th in.), 66 per cent.
Coarse material (above $\frac{1}{16}$ th in.), 33 per cent.

* Ueber die Schwimm-u. Schwebstoffe des Berliner Abwassers." Dr. Monti. Archiv für Hygiene, Band XIV.

Coal picked out by hand from the coarse material, 21.7 per cent. 7.2 per cent. of original material.
Mineral ash in coal, 3.2 per cent.
Ditto in coarse material (*minus* the coal), 44.8 per cent.
Ditto in fine material, 86.5 per cent.

The disposal of this material constitutes a separate problem from the disposal of sludge proper.

(II.) Finely Disseminated Solids.

These consist chiefly of hydrated oxides of iron and alumina, from iron pickling and dye works refuse, clay particles from surface of roads, lime and magnesium salts, and organic matter, alone or in combination with iron and alumina.

All these may be, to a large extent, removed by settlement. A considerable proportion of these matters constitutes the main bulk of what may be termed inevitable sludge.

(III.) Matter in Emulsion or Colloidal Matter.

Beyond what can be removed by settlement there are the matters in emulsion. The removal or oxidation of these matters constitutes a third problem.

The object of the paper is to put on record certain preliminary observations which have accumulated, in regard to matters classified under the last head, more especially in dealing with Manchester sewage, and to indicate where further investigation is necessary.

It will be convenient to refer to these matters as they occur in—

- (a.) Sewage.
- (b.) Effluent from chemical precipitation.
- (c.) Effluent from septic tanks.
- (d.) Effluent from contact beds.
- (e.) Effluent from continuous filters.

(a.) Sewage.

Much information as regards the matters in emulsion may be obtained by submitting the various liquids to dialysis. This method was suggested in the Annual Report of the River Committee for the year ending March, 1901, p. 41. Since then, interesting work has been done by Kröhnke and Biltz,* which shows that a considerable proportion of the oxidisable matter in carefully filtered sewage, "sorgfältig filtriertes Abwasser" (presumably through paper) is incapable of passing through a membrane of parchment. It is, however, important to point out that there are difficulties in obtaining a filtrate of constant composition, by filtration of sewage through paper.

This is illustrated by the following experiment.

A sample of (Moss Side) domestic sewage was allowed to stand until the visible suspended matter had deposited, the top water was then syphoned off, and one portion filtered through coarse filter paper and another portion through fine paper. The filtrate passing through the fine paper in the first two minutes was collected separately from the later portions.

The settled sewage and the three filtrates thus obtained were incubated at 80° F. for six days, both in presence and in absence of air.

The following results were obtained (in grains per gallon):—

* "Ueber organische Kolloide aus Städtischen Abwasser und deren Zustandsaffinität." O Kröhnke and M. Biltz. Hygienische Rundschau, 1 Mai, 1904.

Suspended matter* after incubation at 80° F. for 6 days.

Sample.	In presence of air.			In absence of air.		
	Mineral.	Organic and Volatile.	Total.	Mineral.	Organic and Volatile.	Total.
Raw sewage	0.7	3.1	3.8	1.0	2.0	3.1
" after filtration through coarse paper	0.3	2.4	2.7	—	—	—
" after filtration through fine paper during the first 2 minutes	0.4	2.3	2.7	0.2	0.6	0.8
" after filtration through fine paper after the first 2 minutes	0.2	1.55	1.75	—	—	trace

* The suspended matters in this and the following experiments were determined by extraction in a centrifuge, washing by distillation, drying and weighing.

The following is a description of the samples after incubation in absence of air:—

1. Settled sewage.—Black, very putrescent.
2. Ditto filtered through coarse paper.—Dark coloured, putrescent.
3. Ditto, filtered through fine paper, first 2 minutes.—Dark coloured, putrescent (less degree than 2).
4. Ditto filtered through fine paper, later portions.—Light coloured opalescent, slight putrescence.

Other experiments, in which the sewage was subjected to filtration without previous settlement, have also indicated that during the first few minutes of the operation, a slimy layer forms upon the paper, which retards the passage of colloidal matter.

The method of dialysis furnishes an excellent means of distinguishing between oxidisable matter of a harmful nature and that of a much less complex, and in many cases comparatively harmless character.

In this connection the following comparative experiments between Moss Side and Manchester sewage may be given.

Comparison of domestic (Moss Side) with Manchester Sewage.

Method of Experiment.—750 c.c. of the sample after settlement of visible suspended matter was placed in a glass cylinder; a parchment cylinder containing 750 c.c. of distilled water was then introduced (the relative size of the cylinders being such that the level of the liquids is the same). Portions of the liquid, both from inside and outside the parchment, were taken at stated intervals:—

Interval.	3 Minutes Oxygen Test.				Albumenoid Ammonia.				Chlorine.			
	Moss Side.		Manchester.		Moss Side.		Manchester.		Moss Side.		Manchester.

Ratio	1 to 5.5		1 to 1.6					

In the case of Manchester, the oxidisable matter consists largely of phenolic bodies and sulphocyanates.

It should be mentioned that in order to avoid excessive dilution, no attempt was made to remove the whole of the dialysable matters in solution, the experiment being only continued till equilibrium was attained.

Further experiments show that no deposition takes place on incubation in the case of Moss Side or Manchester, in the liquid which passes through the parchment membrane, whereas in all cases the liquid containing the colloids does deposit on incubation.

The difference above referred to, between Manchester

and purely domestic sewage, can also be shown by simple filtration through paper, the amount of deposit on incubation being greater in the case of domestic sewage than that of Manchester.

It has also been observed that the filtrates obtained by filtering domestic sewage through fine filter paper are more putrefactive than those obtained from Manchester sewage.

The influence of micro-organisms must, however, be forgotten and consequently it is important, in bacteriological examination should be made, side by side with the chemical investigation. This has not hitherto been done.

It is obvious that the work to be done by filters is largely conditioned by the amount of colloidal matter, as this represents potential suspended matter.

Exact knowledge as to the nature of this colloidal matter is at present wanting.

(b.) Effluent from Chemical Precipitation.

It is possible, by suitable addition of chemicals, to greatly decrease the amount of colloidal matter in sewage at considerable expense however, and with the production of an excessive volume of sludge.

Thus, e.g., by heating sewage with basic ferric acetate a crystal clear solution can be obtained.*

It is possible, therefore, by chemical treatment of order to minimise the work to be done by filter beds except under rare conditions, however, the process is generally considered too expensive.

The method of dialysis, in any event, will form a useful

means of showing how far chemical treatment has been effective.

(c.) Effluent from Septic Tanks.

It has been found that the Manchester septic tank effluent, if allowed to stand, deposits quantities of organic matter; deposit also takes place even if the tank-effluent is first filtered through paper.

The following experiments may be given as illustrations:—

* "Das Städtische Siewasser und seine Beziehung zur Flussverunreinigung." M. Rubner. Archiv für Hygiene, Band 2.

I.

in septic tank effluent, allowed to stand at room temperature, in absence of air.

* Slightly overheated in drying.

immediate increase in the mineral matter, and to a tent in the volatile matter, is no doubt partly due to oxidation of ferrous sulphide.

It may be mentioned that where a sample of tank effluent was allowed to stand in absence of air for 12 days a much larger quantity of deposit was obtained.

II.

A sample of septic tank effluent was filtered through fine paper, one portion of the filtrate was incubated (F.) in absence of air; the other, in presence of air, for 11 days.

	Solids in Suspension.		
	Organic and Volatile.	Mineral.	Total.

Samples taken after diffusion was complete.	3 Minutes' Oxygen Test.		Albumenoid Ammonia.	
	Settled Sewage.	Settled Septic Effluent.	Settled Sewage.	Settled Septic Effluent.
I.				
Inside parchment cylinder	0.80	0.66	0.06	0.04
Outside " "	1.20	1.28	0.19	0.165
Ratio	1 to 1.5	1 to 1.9	1 to 3.2	1 to 4
II.				
Inside parchment cylinder	1.20	1.10	0.075	0.085
Outside " "	1.58	1.90	0.16	0.20
Ratio	1 to 1.3	1 to 1.7	1 to 2.1	1 to 2.4

These determinations were to some extent interfered with by the presence of storm water.

Before drawing any general conclusion a large series of determinations are necessary, and also comparative determinations with domestic sewage.

(d.) Effluent from Contact Beds.

Through a filtrate, as it comes from the bed (primary), is comparatively free from suspended matter, it is only observed that deposition takes place on standing in absence of air, leaving the supernatant liquid perfectly clear.

Similar observations have been made by filtration through paper and by dialysis to those recorded in the case of septic tank effluent, with similar results as to the deposition of suspended matter.

another filtered through fine paper. In the case of the fine paper, the liquid passing through in the first five minutes was collected separately from the later portions of the filtrate.

The three filtrates thus obtained were allowed to stand (in presence of air) at the room temperature, for 36 days. The suspended matter which had deposited was then determined as follows:—

	After filtration through Coarse Paper.	First 5 mins. filtrate from Fine Paper.	Filtrate, after first 5 mins. from Fine Paper.
Total	1.8	1.2	1.0
Organic and volatile	1.2	0.8	0.6
Mineral	0.6	0.4	0.4
Per cent. of organic and volatile	72	67	60

Here, also, information is needed with regard to the exact nature of this deposit, but it may be mentioned that some of the iron originally in solution is in a colloidal form, as is shown by the following experiment:—

Iron in solution in septic tank effluent (grains Fe per gallon).

After filtration through paper.	After filtration through porous pot.
0.53	0.225
(Means of ten determinations).	

In studying the effect of septic action on sewage, examination by dialysis will afford useful information.

The following experiments appear to indicate that of the oxidisable matters in the Manchester septic tank effluent a slightly greater proportion is colloidal than in the settled sewage:—

Comparison of Settled Septic Tank Effluent with Settled Sewage.

Method of Experiment.—Similar to that used in the comparison between Moss Side and Manchester Sewage:

Results in Grains per Gallon.

The character of the matter depositing is, however, undoubtedly different in the case of the effluent from contact beds from that in sewage and septic tank effluent, but further experiment is needed in order to exactly determine this difference.

The following is an analysis of the matter deposited, after standing in contact with air, in the effluent from single contact beds in Manchester:—

Organic and volatile,	58.3 per cent.	
Mineral,	43.7 per cent.	Calculated on total dry matter.
Mineral Matter	Contains	
Silica	8.4 per cent.	3.8 per cent.
Fe ₂ O ₃	52.7 per cent.	23.0 per cent.
Al ₂ O ₃	12.8 per cent.	5.6 per cent.
CaO	13.3 per cent.	5.8 per cent.
Total nitrogen in dry matter	—4.7 per cent.	

The following experiments were made, in order to determine the effect of aeration, under different con-

ditions, on the amount and character of the suspended matter, and on the oxidisable matters in solution, as measured by the three minutes' oxygen test, and in the second case also by the proportion of nitrate.

The samples were divided among several bottles, and exposed to the following conditions:—

- Air bubbled through continuously.
- Standing in closed bottles at room temperature.
- Standing in closed bottles in incubator (80° F.).
- Standing in partially-filled bottles at the room temperature.
- Standing in partially-filled bottles in incubator (80° F.).

The results obtained, after different periods of time, are given in the following tables:—

I.—Sample from Primary Contact Bed, Five Minutes after Opening the Exit Valves.

(c.) Effluent from Continuous Filters.

The effluent from an open continuous filter in good order, will contain suspended matter in a granular condition.

Our observations show that this suspended matter, if incubated by itself, in absence of air, still contains sufficient organic matter to become putrefactive.

It is worthy of investigation whether, as the age of the filter increases, this suspended matter, besides increasing in amount, does not also become of a more noxious character.

Information is required as to the amount of colloidal matter still present, after settlement of the granular suspended matter, and the consequent possibility of further deposition taking place.

With continuous filters of fine grade, although no suspended matter may pass away in the effluent, a certain amount of accumulation is ultimately bound to take place in the bed.

Summary.

In addition to the ordinary sludge obtained by settlement of the sewage, the sewage chemist is faced with the disposal, ultimately, of the residue left after transformation of the colloidal matters in pseudo solution or emulsion.

Experiments are in progress, in order to determine what proportion of these can be actually oxidised by bacterial activity, and what proportion will have eventually to be dealt with and removed from the filtering medium by washing or screening.

DISCUSSION.

Mr. WM. THOMSON wished to know whether a microscopic examination had been made of the matter which precipitated from the clarified sewage on standing, and, if so, whether it did not consist of bacteria or fungi. Was it possible that the colloidal bodies were due to bacterial organisms which continued to die in the effluent?

Dr. J. GROSSMAN said that 18 months ago he had engaged by the Bradford Corporation to design an installation for the recovery of fat and manure from sewage sludge, which was now in work. His first impression was that the process could only be used where sewage, owing to local circumstances, contained a large amount of fat. But he had come to the conclusion

it would be possible to apply his system to a great many towns. The general applicability of the method would to some extent depend upon the amount of colloidal matter contained in the sewage, and Dr. Fowler's researches and his method of determining the amount of colloidal matter would be of assistance in future practical work. Up to the present the tendency in sewage purification had been to reduce the amount of sludge to a minimum, as the sludge obtained was in nearly every case a nuisance and expense. For that reason, where precipitant was used, the quantity of the latter was insufficient to precipitate the colloidal matter, which thus passed away in the effluent. But colloidal matter contained various manurial constituents which during their passage through the contact beds were wasted. It would, in future, be necessary to ascertain the exact balance between the quantity of precipitant and the quantity of colloidal matter thrown down, which would give the best commercial result in the working up of the sludge. The extra quantity of the latter would be compensated for by the increased value of the products obtained by its distillation.

Mr. E. HALLIWELL (Preston) agreed with Dr. J. GROSSMAN that the question of suspended matter in effluents was of great importance, and had hardly received the consideration to which it was entitled. In the case of spray filters, the suspended matter in the effluent was present in variable quantities, but as it contained a large proportion of the organic matter it was necessary that it should

ed During the first week, or even months, of the g of a filter the quantity was in some cases very but after some time the suspended matter began to and in many cases would average about 10 parts 0,000. If the revolution of the sprinkler arms were d by the wind or other causes, the amount was very larger and a very foul effluent was produced. The al matter probably accounted for some of the ded solids, but the main cause was the suspended present in the tank effluent. At Nelson it was found approximately 6,000 gallons of wet sludge, containing ent., of solid matter, was deposited from 6,000,000 of effluent from sprinkler filters.

BAILEY said that in his own experience he had cross somewhat similar difficulties as Dr. Fowler, nating the impurities in the Manchester atmos-

He had been astonished to find that in times of air of Ancots compared very favourably with that Owens' College district in regard to the amount of y. Yet there was a great difference in quality. the air in the neighbourhood of the College was rated with carbon and matter which was only acted upon by oxidising agents, that of Ancots had nient amount of matter which seemed to resemble wler's colloidal matter, and oxidised much more

He had been able to differentiate between these s to some extent by using alkaline and acid s of permanganate and bichromate of potash, and erience led him to appreciate fully the great nee of investigation of sewage along the lines d.

CHAIRMAN said that in Salford they treated the f the sewage with lime and iron salts, and it was due to this process that suspended matter pre- and in passing through the tanks it did not settle. e experimented with the effluent by allowing it in for three or four hours in the tanks and at the hat time he found about $1\frac{1}{2}$ to 2 grains per gallon on. The Salford Corporation had spent about during the past 12 months in trying to overcome feculty of suspended matter, but had met with ecess.

FOWLER, in reply to Mr. Thomson, said that opical examination of sewage effluents showed som f bacteria and also the higher forms of life. He pretend to have more than touched the fringe subject. They needed to make complete organic y of all these products, and that was difficult to much as it took a very long time to obtain the y quantity of materials. The Chairman had y misunderstood him with regard to filtered It was not what could be seen in the effluent, potential matter contained therein, that he was ncreased in. If he (the Chairman) were to in- e the potential matter in the Salford tank-effluent, it find some interesting facts. With regard to ble suspended matter, the average in Manchester was about 32 grains per gallon, but in storm might run up to 700. In reply to Dr. Grossman, not think the valuable constituents of the matters were lost. Manure had to undergo a amount of fermentation before it was useful for aral purposes, and when this humus was washed o filter beds and mixed with a little lime, it consti- d excellent manure.

ANALYSES OF SENNA.

BY RUSSELL W. MOORE, M.A., M.SC.

Testing of senna for customs purposes presents no ies; 10 grms. of the drug are boiled in a litre flask

with water, and the contents of the flask made up to the mark and thoroughly mixed; 200 c.c. are filtered off and evaporated to dryness on the water bath and the residue dried in the steam oven to constant weight. Attempts to extract with water in a Soxhlet tube were unsuccessful, as the extraction was extremely slow, and even after long continuance was incomplete. The Treasury regulations require 28 per cent. of "soluble matter." The following results were obtained from six different samples: 34.37, 32.75, 39.00, 38.54, 39.44 and 38.28 per cent. soluble matter—average 37.06 per cent.

The results being well above the required standard in every case, indicate that importations of senna are generally of good quality, and that there is no great necessity for frequent chemical analysis.

Meeting held at Chemists' Club, on Wednesday, April 19th, 1905.

MR. RUSSELL W. MOORE IN THE CHAIR.

THE DETERMINATION OF ACETIC ACID IN WHITE LEAD.

BY GUSTAVE W. THOMPSON.

In the manufacture of white lead by any process involving the use of acetic acid, a certain portion of the acetic acid seems to be bound firmly so that it cannot be washed out in any ordinary process of manufacture. The amount of the acetic acid which is fixed by the white lead depends largely upon the quantity used in the process of manufacture. As to whether this acetic acid is objectionable or not, I do not propose to speak in this paper further than to say that there is a popular impression that the acetic acid should be as low as possible. The Navy Yard specifications demand a white lead which shall not contain "acetate in excess of fifteen one-hundredths of 1 per cent. of glacial acetic acid." It seems reasonable, furthermore, that whether the acetic acid is objectionable or not, the intelligent purchaser of white lead should be enabled, as far as possible, to know what he is buying, and perhaps trace back results to some definite cause.

I am unable to state the form in which the acetic acid is combined which renders it insoluble in water. The following facts may be somewhat of an indication, however, in this matter: An ordinary lead acetate solution will take up varying amounts of lead oxide to form basic lead acetate. The more concentrated the lead acetate solution is, the less basic will be the formed acetate; for instance, the ordinary pharmacopœia solution—"Liquor Plumbi Subacetatis"—contains two equivalents of lead to one of acetic acid, and, while this solution may be made more basic than this by adding an excess of litharge, the amount of litharge which it will take into solution in excess of that required to form the pharmacopœia solution is comparatively small. Working with dilute solutions of lead acetate, however, solutions can be obtained containing as much as ten equivalents of lead to one of acetic acid. These very basic dilute solutions may, however, be regarded by some as supersaturated solutions, for the reason that the basic lead tends to separate out on slight provocation, carrying with it some acetic acid. If this very basic lead acetate, which separates out, is washed with distilled water, it appears to form a colloidal solution, from which the basic lead is readily precipitated in the presence of suspended inert material, and especially in the presence of electrolytes. Ordinary water is usually used for washing white lead, and, as this water contains more or less saline substances, any of this extremely basic acetate that is present will be precipitated with the white lead, and go into the finished product.

I have tried a great many processes for the determination of acetic acid in white lead. Very few white leads will show the presence of lead acetate by the iodide test, provided a thoroughly clear extract is obtained before

adding the reagent. Potassium iodide will, by itself, slowly give a yellowish tint to white lead, but the amount of lead which may be dissolved out by distilled water from a white lead is no measure of the amount of acetate present, for the reason that the longer the white lead is washed with distilled water, the greater will be the amount of lead dissolved, colloidal solutions apparently being formed. Unsatisfactory results seem also to be obtained when one endeavours to carry out the acetic ether test with the use of alcohol and sulphuric acid, applying the test directly to the lead carbonate. Inasmuch as the amount of glacial acetic acid present in white lead ranges from 0.05 per cent. in Dutch process white lead to 0.7 per cent. in some precipitated white leads, it will readily be seen that the acid should first be isolated before any qualitative test can be properly applied to it; and I have reached the conclusion that the easiest way to test qualitatively for acetic acid in white lead is really to determine it. Practically all of the methods that have been recommended for the determination of acetic acid in white lead involved its distillation. I have used three different methods for conducting this determination, and have finally rejected two and adopted the third. The two methods rejected are:—First, the determination involving the boiling of the white lead with sodium carbonate supposedly to form sodium acetate, filtering out the undissolved lead, acidifying the filtrate with sulphuric acid, and distilling to recover the acetic acid. This method appears to be objectionable, for the reason that all of the acetic acid present in the white lead is not obtained by this method; some of it remains unaffected by the sodium carbonate. The second method is that recommended by Lunge, in his "Methoden," which consists in treating the white lead with dilute sulphuric acid, and distilling the acetic acid thus liberated. The objection to this method is the same as that found to the method involving the treatment of the white lead with sodium carbonate, namely, that all the acetic acid is not liberated by the treatment. It is to be noted, even, that white lead can be heated with strong sulphuric acid until fumes are evolved without a complete decomposition of the carbonate present. The method finally adopted is as follows:—

18 grms. of the dry white lead are placed in a 500 c.c. flask, this flask being arranged for connection with a steam supply, and also with an ordinary Liebig condenser. To this white lead is added 40 c.c. of syrupy phosphoric acid, 18 grms. of zinc dust, and about 50 c.c. of water. The flask containing the material is heated directly and distilled down to a small bulk. Then the steam is passed into the flask until it becomes about half full of condensed water, when the steam is shut off and the original flask heated directly and distilled down to the same small bulk—this operation being conducted twice. The distillate is then transferred to a special flask and 1 c.c. of syrupy phosphoric acid added to ensure a slightly acid condition. The flask is then heated and distilled down to a small bulk—say, 20 c.c. Steam is then passed through the flask until it contains about 200 c.c. of condensed water, when the steam is shut off and the flask heated directly. These operations of direct distillation and steam distillation are conducted until 10 c.c. of the distillate require but a drop of N/10 alkali to produce a change in the presence of phenolphthalein. Then the bulk of the distillate is titrated with N/10 sodium hydroxide, and the acetic acid calculated. It will be found very convenient in this titration, which amounts in some cases to 600—700 c.c., to titrate the distillate when it reaches 200 c.c., and so continue titrating every 200 c.c. as it distills over.

The details in this described method, as regards the supply of steam from an outside flask, its condensation and subsequent evaporation, are not essential to the process, but can, of course, be modified so as to conform to the ordinary method of distilling acetic acid from acetate of lime. If the white lead contains appreciable amounts of chlorine, it is well to add some silver phosphate to the second distillation flask, and not to carry the distillation from this flask too far at any time. If the dry white lead under examination has been obtained by extraction as a residue from white lead paste, it is well that this

extraction should be exceedingly thorough, as, other fatty acids may be held and distilled with the acetic. Even then, they will not interfere with the final titration as they may be filtered from the distillate before titration should that be desired.

Meeting held at Nottingham on Wednesday, March 1905.

MR. J. T. WOOD IN THE CHAIR.

THE COMPOSITION OF SCOURING SOAP

BY T. A. GERARD.

The user of soap for scouring textiles usually as the percentage of fatty acids. The amount of free fat is presumed to be inconsiderable and hence not ordinary analysis, often separated from the combined fatty acids. The amount of free fat, however, always inconsiderable. Various samples of soap for scouring textiles, were found to contain as much as 2.7 per cent. unsaponified fat. As the usual guarantee percentage of fatty acids is 62, if the free fat is included, the amount of saponified fat may be 59.3 which would be a loss to the consumer. The free fat and the combined fatty acids should be always separately, the latter being admittedly the only portion of the scouring soap. If a maximum of free fat, not over 0.6 per cent., could be specified, would be an advantage to the buyer, as it would preclude the use of fat containing over 1 per cent. saponifiable, and ensure the soap being skilfully made. Free fat is not only useless, but neutralises the effect of a considerable amount of the combined fatty acids. Moreover, when the amount much exceeds 0.6 per cent., the goods scoured run a risk of being damaged. There is a temptation to use the cheapest fats in the manufacture of scouring soaps. These cheap fats are usually incompletely saponifiable. The following are from a series of tests made recently in the laboratory of my firm:—

White tallow (refined)	0.02—0.03	unsaponifiable
Brown " " " "	0.20—0.65	" "
Bone grease " " "	0.40—2.42	" "
Skin grease " " "	1.45—7.10	" "
Olein " " "	1.20—8.60	" "

Recovered greases from 7 per cent. to 50 per cent. All these are offered to soapmakers as materials for the manufacture of scouring soaps.

DISCUSSION.

Mr. S. J. PENTECOST said that no doubt by chemists and dyers fell into the common error of buying from the percentage of fatty acids given on analysis, without taking the trouble to ascertain how much free fat might be included in this percentage. In the case of materials such as cottons or silk goods, soaps containing free fat were not only bad economically, but they also in some extent with the lustre and finish of the goods. He had always found that for scouring cotton goods, a tallow soap gave better results as a detergent than one made from the oleins (specially those distilled from grease, or those containing resin, and Mr. Gerard's opinion seemed to confirm that opinion. Could Mr. Gerard say what was the exact nature of the unsaponifiable matter found in the oleins he had referred to in his figure?

Mr. S. R. TROTMAN said he could speak from experience as to the truth of Mr. Gerard's statements. The percentage of unsaponifiable matter in soap was frequently found to be high, and the fact that they were made with benzine recovered and that a sufficiently volatile spirit had not been used

traction. Much care was required in the selection for this purpose, as if they contained any con- portion boiling above 120° C., it was extremely to recover it from the grease. He had on several come across cases of trouble in hosiery and ds, which were undoubtedly due to the presence which had been introduced with soap, and he d, from experiments made in his laboratory, that a goods were treated with a soap containing free t was practically impossible to subsequently this grease by washing with water or neutral water, and this residual grease, which was retained res, was undoubtedly the frequent cause of sub- rouble, such as patchiness in dyeing.

ARCHBUTT asked the nature of the "White which contained only 0.02 per cent. of unsaponi- lter. He thought a good soap should contain 63 per cent. of fatty acids. Mr. Trotman's re- minded him of a statement made by Dr. Perkin isussion on a paper published in the current

number of the journal (March 15, p. 227), that if wool were worked in water containing olive oil and carbonate of potash and then rinsed in clean water, oil could not be squeezed out from the wool in quantity, whilst cotton under the same condition retained very little oil. He thought this might have a practical application other than in connection with dyeing.

Mr. T. A. GERARD, in reply, said there were three reasons for olein containing unsaponifiable matter. They were:— (1) Overheating in the distillation; (2) it was made from recovered greases which greases contained unsaponifiable matter; (3) adulteration.

As to obtaining a good sample, the white tallow was specially prepared, as it was to be used for particular work, toilet soap for instance. He was told that 62 was the recognised percentage of fatty acids to specify, but he only put that as a minimum. The percentage was generally greater. Impure greases were mostly used for brown household soaps for export, but very bad greases were made into a close soap for wire drawing.

ANT, APPARATUS & MACHINERY.

ENGLISH PATENTS.

Impts. in —. A. Smallwood, London. Eng. Pat. 9924, April 30, 1904.

Box or grate of the furnace communicates with a chamber, above which is an arch of refractory. From the latter a number of projecting pieces downwards; these pieces, which may have the ridges or "draught-board" pattern projections, mix the gases, and, by becoming incandescent, heat, so that complete combustion is secured.—

Centrifugal; Liners for —. A. L. nson, Stockholm. Eng. Pat. 10,422, May 6, Under Int. Con., May 16, 1903.

Pat. 779,990 of 1905; this J., 1905, 147.—T. F. B.

Devices for Evaporating Liquids and for other res; Impts. in —. A. B. Lennox, Newcastle. Eng. Pat. 15,733, July 15, 1904.

casing having inlet and outlet orifices, is fitted nical screw-down valve. The valve seat or the radial tangential or helical grooves formed upon

its surface, so that the liquid may issue in jets, which impinge upon one another, in order to produce a spraying action, which may be regulated by altering the position of the valve. To allow the valve to be used to close the orifice entirely, the grooves are stopped short of the inner end of the cone.—W. H. C.

Extracts and the like; Apparatus for Making —. J. W. Mackenzie, London. From J. U. Lloyd, Cincinnati, U.S.A. Eng. Pat. 25,216, Nov. 19, 1904.

UNITED STATES PATENTS.

[Separator] Machine; Centrifugal —. K. P. Nilsson, Stockholm. U.S. Pat. 785,910, March 28, 1905.

THE bowl of the centrifugal machine, fed through the opening 1, has the discharge openings 3, for the "slime" placed at a shorter radial distance from the spindle 4, of the machine than the openings 2 for the liquid. Screws 5, enclosed in chambers and driven by the gearing 6, from the shaft 4, are arranged to draw the "slime" from the outer part of the bowl and to deliver it by means of the wings 7, through the discharge openings 3.—W. H. C.

Separators, Centrifugal: Liner for —. C. A. Hult and O. W. Hult, Stockholm. U.S. Pat. 787,179, April 14, 1905.

THE bowl of the centrifugal separator, provided with a central inlet pipe, has an annular depression formed in its bottom. The liner consists of a number of vertical plates or blades, which are held in position by being threaded on a ring passing through holes in the plates. The blades are adjusted to intersect the radii of the bowl, and have passages in their lower edges through which the liquid can flow.—W. H. C.

FRENCH PATENT.

Distilling and Making Extracts: Apparatus for —. J. V. Lloyd. Fr. Pat. 348,251, Nov. 25, 1904.

SEE U.S. Pat. 777,115 of 1904; this J., 1905, 78.—T. F. B.

GERMAN PATENTS.

Filter Element. W. Hartmann. Ger. Pat. 154,314, Nov. 1, 1902.

THE filter element is composed of a number of thin perforated plates with grooves or furrows on both sides, and placed one above another in such a way that the grooves of neighbouring plates cross one another, whilst the perforations are all in vertical alignment, forming a number of collecting channels. The plates may be held together by a perforated tube passing through one of the collecting channels. According to one claim, the filter element is composed of annular plates forming a cylinder, the liquid to be filtered being delivered at the inner and outer circumferences of the plates, and the filtrate discharged through the channels formed by the perforations of the plates.—A. S.

[Separator] Centrifugal Apparatus. H. Rahrbaeh and W. Goergen. Ger. Pat. 154,351, Nov. 21, 1902.

THE centrifugal apparatus claimed has a number of separating spaces, in the form of closed conical chambers, arranged one above the other. The conical division walls of the chambers are arranged on a central, axial tube, and the inner walls of each chamber are provided with furrows or are made in a corrugated form in order to expedite the separation.—A. S.

[Separator] Centrifugal Apparatus. H. Rahrbaeh and W. Goergen. Ger. Pat. 154,352, Nov. 21, 1902.

IN centrifugal apparatus with division walls of the kind described in Ger. Pat. 48,615, these walls are provided with furrows or grooves of such a shape that the separating space is increased in a radial direction.—A. S.

II.—FUEL, GAS, AND LIGHT.

ENGLISH PATENTS.

Gas; Process and Apparatus for the Manufacture of Combustible — from Peat and like Substances. C. Whitfield, Kettering. Eng. Pat. 1738, Jan. 23, 1904.

IN the production of combustible gas from peat and like substances, the heat of the producer gas is utilised for evaporating the moisture in the fuel. For this purpose the top of the producer is fitted with a heating chamber, which is encased by an outer shell or surrounded by a coil and closed at the top by a plate provided with a charging hopper. The hot gas is caused to circulate through the jacket or coil around the heating chamber, evaporating the moisture from the peat prior to its entering the producer. Simultaneously the gas is cooled and prepared

for subsequent treatment. The moisture thus evaporated is mixed with air if required after condensing part and conveyed to the ash-pit or lower part of the producer where it is used for maintaining the combustion of the —R.

Gas; Process and Apparatus for Generating Combustible — from Hydrocarbonaceous and other Solid Fuels. B. H. Thwaite, London. Eng. Pat. 7347, March 1904.

THE combustion of a column of solid fuel is initiated at the upper level by the introduction of a certain proportion of air, sufficient to cause the evolution of the more volatile hydrocarbons. By a secondary admission some distance below the upper level, the lower part of the column of fuel is maintained at a high degree of incandescence. The downward direction of the combustion is maintained by pressure or by aspiration. Moisture contained in the fuel and hydrocarbons is liable to recondense after volatilising, are thus caused to pass through the high-temperature zone of combustion, where the hydrocarbon vapours are made more or less permanent, while the moisture is dissociated into free hydrogen and oxygen, the latter combining with carbon to form carbon monoxide. The apparatus consists of a cylindrical steel or iron shell lined with refractory material and provided on its base with a central outlet tube capped with a steel cover from which the gas is suspended. The steel shell is supported on standards, and the whole is placed in a water bath, which keeps the fire-bars cool and prevents the gas from entering into the outer air. The bottom of the water bath is conical; the incumbering ash and clinker slide down the slope to a point outside the shell of the generator, and are readily removed. The gas is exhausted by means of a fan or blower, located behind the condensing apparatus and forced into a pressure governor to establish a constant gas pressure supply to the engine.—R. L.

Gas Generators; Improvements in — and in the Manufacture of Gas. J. Radcliffe, Thornton Heath, London. Eng. Pat. 7592, March 30, 1904.

THE generating chamber, fitted with gas outlet feeding hopper, is combined at its lower end with an inclined revolving chamber. By introducing a pondering proportion of air, or air and steam, to the chamber directly and a small supply only at the top of the revolving chamber the combustion is maintained entirely in the fixed chamber, while the revolving chamber is chiefly employed as a receptacle for the hot material, removing them from the generating zone and delivering them to the passing part of the air blast which is heated on its way to the generating chamber. The chamber is of a frusto-conical form, or cylindrical upper end and frusto-conical or curved inwardly lower end. The ashes, when at rest, must be inclined at an angle of about 42°, which is the "natural slope" of the material being dealt with.—R. L.

Gas Producers; Impts. in —. A. H. Lynn, London. Eng. Pat. 9668, April 27, 1904.

THE gas producer is operated in a similar manner to a blast-furnace, the steam being introduced separately at the air blast and at a point above the air blast. Part of the hot gases are removed at a point immediately above the hottest zone, but below the steam inlet. By these arrangements, the upper part of the producer, which may be regarded as the principal seat of the decomposition of ammonia, does not become too hot, and the decomposition of ammonia by excessive heat is avoided. If it is desired to run off the ash as slag, any fluxing material required is charged by means of suitable hoppers into the hottest zone and not into the top of the producer —L.

Gas Producing Apparatus; Construction and Use of —, for use with Fuels of a Bituminous Nature. H. G. Hills and H. Lane, Hyde, Cheshire. Eng. Pat. 10,733, May 10, 1904.

THE "producer" part of the apparatus consists of a vertical iron shell lined with refractory material, and

t the top with a hopper closed by a lid, whilst its extremity dips into a vessel containing water. The part communicates with a separate vaporiser by of a pipe. Inside the bottom of the producer is an annular grate composed of several hollows connected to "up take" and "down take" embedded in the refractory lining of the case. The is enclosed in a sheet-iron jacket, provided with passages" near the top and bottom.

use the apparatus, a fire is lighted in the prod and fuel fed in from above. The products of combustion pass downwards, and flow through the annular grate, heating it. They then pass to, and external vaporiser which is divided into two compartments by a central plate, and are then led to a chimney for an initial draught. The air required for combustion enters the sheet-iron jacket surrounding the producer and gets heated in its passage downwards. It then in the bottom belt passage and passes into the r, where its temperature is raised by coming into with surfaces heated by the outgoing products of ion. It is here saturated with moisture, by allowing of water, regulated by suitable means, to flow spiral cut on the internal surface of the vaporiser, passes to the upper belt passage of the producer. o belt passage it passes down the "down takes" the grate, and through the "up takes" to the producer, which it reaches in a very hot condition. Then passed down through the fuel, and drawn off bottom, as before described. The chimney is only to provide an initial draught, and may be replaced for drawing off the products of combustion.

—L. F. G.

arts; Impts. in —. R. Dempster and Sons, Elland, Yorks. and F. Scott, Galashiels, N.E. Pat. 10,926, May 12, 1904.

ate the disadvantages of a covered subway in the furnaces of gas-retorts, the roof of the subway is covered with and replaced by a travelling platform of size and construction, arranged level with the floor and adapted to run along rails supported by iron bolts to the buckstays or brackets, thus access to the mouths of the retorts. The platform is provided with ball-bearings and is fenced all as the subway, to prevent accidents.—R. L.

other Impurities from crude Illuminating Gas, or Power Gases; Method of Extracting —. J. Witt, Ilkley. Eng. Pat. 13,316, June 13, 1904.

of (circular) iron wire screens are spaced about of an inch apart by metal rings at their circumference, kept taut, and fixed vertically in the central of a horizontal iron vessel. The gases to be treated traverse the screens at right angles, and are intermittent puffs of exhaust steam issuing from the bottom of steam ports or orifices in the upper of the metal rings above referred to. The tarry matter thus deposited on, and washed down from the bottom, and drawn off by sealed pipes "in the usual manner."—L. F. G.

proved Process for the Purifying or Desulphurising of Illuminating Gas —. J. Marschal, Bruxelles.—St. Gilles, m. Eng. Pat. 28,765, Dec. 29, 1904.

ETTED hydrogen can be removed from crude gas by means of ozone either by causing the ozone to act directly on the gas, or by previous "causticising" (i.e., rendering active) of ammonia water by ozone, or by simultaneous use of the two processes. Ozone or air is conveyed into a column provided with discs, or a distilling column, which receives the crude gas, water. The latter gives off its sulphur in the form of an impalpable powder which settles down. The gas, water is decanted and may be used again for the purification of gas.—R. L.

rodes; Arc Lamp —. R. Fleming, Lynn (Mass.), U.S. Eng. Pat. 7298, March 26, 1904. Under Internat. Conv. March 26, 1903. The electrodes are formed of iron tubes filled with magnetic material, the free end being fused so as to render it rigid and enable the arc to be readily started.

Tubes of other metals may be used, filled with the corresponding oxides, or with the salts used for making flame carbons.—C. S.

Electrodes; Arc Light —, and Methods of Making Same. J. T. H. Dempster, Schenectady (N.Y.), U.S.A. Eng. Pat. 7299, March 26, 1904. Under Internat. Conv., March 26, 1903.

AN iron tube or shell is filled with a core prepared from about 80 per cent. of magnetic iron oxide (Fe_3O_4), 18 per cent. of red oxide of iron (Fe_2O_3), and 2 per cent. of substances capable of lowering the fusing point of the mixture (preferably potassium titanate and caustic potash). The mixture is made into a plastic mass with a little water, and 5 per cent. of glycerin or other liquid of low volatility; and the moulded cores are dried, baked to expel the glycerin, and fired at about 1200° C. in crucibles packed with granular material, to prevent undue reduction and distortion. When introduced into the outer shell, the arc end of the pencil is fused over to make it conductive; or the pencils may be exposed to fusing heat in the muffle.—C. S.

Electrodes for Arc Lamps, and Method of Making Same. W. S. Weedon, Chester (Pa.), U.S.A. Eng. Pat. 26,921, Dec. 9, 1904. Under Internat. Conv., Dec. 10, 1903.

THE electrodes are made of titanium sub-oxide, by heating a mixture of seven parts of rutile with rather more than one part of carbon to 1500°—2000° C., the mass being moulded into pencils with the aid of water and glycerin. Owing to the high luminosity of the arc, the positive electrode may consist of copper or other good conducting material of sufficient dimensions to prevent injurious oxidation.—C. S.

Gas-Furnace. J. C. Swindell, Allegheny, Pa. U.S. Pat. 787,131, April 11, 1905.

THE furnace as shown in the figure consists of a combustion chamber placed below the furnace-chamber. From the combustion-chamber the waste gases pass downwards through a flue to a horizontal waste-gas channel below, in flowing through which, they heat the incoming air, which enters through a channel adjacent to the horizontal waste-gas channel.—W. H. C.

Electrode for Arc-Lamps and Method of Making Same. J. L. Roberts, New York. U.S. Pat. 786,518, April 4, 1905.

THE electrode consists of a metallic tube filled with a rod or roll of wire-gauze, the interstices of the latter being filled with a pulverised refractory material, containing chromium particles of which are bound together by means of some "carbonizable" substance.—W. H. C.

FRENCH PATENTS.

Fuel; Manufacture of Agglomerated —. E. P. L. Mors and A. D. J. A. Nobécourt. Fr. Pat. 348,289, Feb. 3, 1904.

IN order to obtain a porous block of fuel which will retain its shape until consumed, the fine coal is agglomerated with such materials as glue, gums, starch, &c., with the addition at the time of agglomeration, of either wood, sawdust, peat, "fat" coal, and alkali carbonates or nitrates, the last-named being added in such proportions that a clinker which is partly porous is obtained. The blocks are either heated or partly carbonised before use in order to obtain a block full of cavities separated by only thin partitions of combustible matter.—W. H. C.

Combustible; New Agglomerated —. G. M. Larondie. Fr. Pat. 348,475, Feb. 10, 1904.

PAPER, rags, or wood are sprinkled with water and allowed to rest for 48 hours. The mass is then placed in a mixer, and treated with a 5 per cent. solution of sodium carbonate till it forms a fairly thick paste. The paste is transferred

to another mixer and treated with a 1 per cent. solution of hydrochloric acid, till stiff. Ten parts of this product are then mixed with 90 parts of fine coal, and sprinkled during mixing with a 1 per cent. solution of commercial nitric acid, which partially converts the cellulose of the paper, &c., into pyroxylin. The quantity of nitric acid required must be exactly calculated, so as to form only the compound $(C_{12}H_{13}(NO_2)_2O_{15})_n$. The mass is then dried and pressed into moulds.—L. F. G.

Fuel; Artificial — C. H. Carpenter and S. L. Davis. Fr. Pat. 348,515, Nov. 19, 1904.

SEE Eng. Pat. 24,336 of 1904; this J., 1905, 189.—T. F. B.

[*Fuel*] *Briquettes; Manufacture of* — W. Simpkin and J. B. Ballantine. Fr. Pat. 348,578, Dec. 5, 1904. Under Internat. Conv., June 23, 1904.

SEE Eng. Pat. 14,213 of 1904; this J., 1905, 189.—T. F. B.

Combustible. E. La Combe. Fr. Pat. 348,606, Dec. 6, 1904.

FIFTY to 40 parts of crude naphthalene, 40 to 50 parts of coal dust, and 10 parts of rosin are mixed together by suitable means. This mixture melts at 50° C., and becomes very liquid at 65° C. For use as a fuel it is fed into the furnace in the solid condition, or sprayed in when melted.—L. F. G.

Combustible; Artificial — and *Process for Obtaining same*. W. B. Hartridge. Fr. Pat. 348,627, Dec. 7, 1904. Under Internat. Conv., Dec. 9, 1903.

SEE Eng. Pat. 26,974 of 1903; this J., 1905, 78.—T. F. B.

UNITED STATES PATENT.

Wood Distilling Plant. C. M. Palmer, New London, U. S. Pat. 786, 144, March 28, 1905.

A HORIZONTAL retort is provided with rails along which run cars which carry the wood to be distilled. The retort is provided with a perforated horizontal steam-inlet at one end of the retort is closed by an adjustable steam-inlet at one end of the retort is closed by the steam pipe of the outermost car. The retort into which the cars are run is closed by a cap, which is screwed in position during distillation.—T. B.

FRENCH PATENTS.

Distillation [Tar]; Continuous — E. Ray. Fr. Pat. 348,267, Nov. 26, 1904.

ues of horizontal tubular retorts 1, 2, 3, 4, 5 are as shown, in suitable heating chambers above a pier, from which the hot gas passes first under the retort 5 of each series, and then under 4, 3, 2, 1 in the indicated direction to that taken by the material to be dyed. The retorts are set with a slight inclination, in the directions, the lower end of one retort being connected by the pipes and valves 6, 6 with the upper end of the next in the series. The tar is fed into retort 1, by a valved pipe 7 and the funnel and siphon pipe 8, and through the retorts 1, 2, 3, 4, 5 successively, in a stream over the portions of the retorts that are most highly heated, the residue (pitch) being run out of the retort 5, continuously by the valved siphon pipe 9. Different fractions are led away to separate condensers receivers by the pipes 10, 10. One producer serves two re-batteries of retorts, and the regulation of the heat is controlled by altering the amount of secondary air and by admitting a portion of the hot gas directly to the retorts by the ports 11, provided with dampers opened from without.—W. H. C.

nions; Preparation of Hydrocarbon —, and their Application for the Degreasing of Textiles. E. Saint-vaire and E. de Grousseau. Fr. Pat. 348,501, Nov. 1904.

RESOLUBLE emulsions of hydrocarbons or their derivatives, are obtained by incorporating the hydrocarbon with an aqueous emulsion "of an albuminoid such as carrageen" (obtained from seaweed of the *fucus* type) or from alkaloidal compounds, such as emulsine (Panama wood). One kilo. of emulsine or carrageen added with 75 litres of water, the solution is filtered and heated to about 20° C., and 30 kilos. of the substance which is intended for emulsifying (petroleum spirit, naphtha, benzene, a tetrachloride, &c.), is vigorously stirred into it, in all quantities at a time; the emulsion thus produced is used for degreasing by simply dissolving in water. It is intended for scouring textiles, a salt such as an chloride, sulphate, carbonate, or silicate may be incorporated with the emulsion; for removing grease surfaces, a sandy substance may be added. The resulting emulsions are stated to be miscible with water in all proportions, even very hard waters. Compare it. 346,831 of 1904; this J., 1905, 238.—T. F. B.

a; Paraffin Wax —. M. F. L. Colignon. Fr. Pat. 348,277, Nov. 16, 1904. XIII. A., page 506.

IV.—COLOURING MATTERS AND DYE STUFFS.

Hydroxyanthraquinones and their Sulphonic Acids; Mordant-Dyeing Properties of the —. G. v. Georgi. Z. Farben-u.-Textil-Ind., 1905, 4, 185—192.

In consequence of Möhlau and Steimmig's criticism of his researches on this subject (this J., 1902, 1530), the author adduces further evidence in support of his own conclusions. The theory advanced by these authors, that if a hydroxyl group is adjacent to the chromophoric element in an aromatic hydroxy compound, the latter will act as a mordant dyestuff, is in the author's view on the verge of general acceptance. Not only have the mordant effects exhibited by hydroxyls when in the ortho-position been disregarded, but the fact has been overlooked, that quinizarin, in spite of the attachment of its hydroxyls in ortho-position to the chromophoric carbonyl group, possesses inferior dyeing properties to hystazarin, in which the hydroxyls are in the β -position. From a comparison of the dyeing properties of trihydroxyanthraquinones with quinizarin, it is inferred, that the most essential difference is exhibited by 1,2,3-trihydroxyanthraquinone (anthraquinone), whilst the 1,2,4-derivative (purpurin) displays the dissimilarity. Of the remaining compounds, the 1,2,6- and 1,2,8-derivatives are further removed from

alizarin than the 1,2,6- and 1,2,7- types, whilst the change is more marked in the 1,2,5- than the 1,2,8- compounds, the former giving with alumina a bluer red than alizarin. 1,4,5-Trihydroxyanthraquinone gives paler shades than 1,4-dihydroxyanthraquinone (quinizarin). 1,4,5-Tetrahydroxyanthraquinone is practically devoid of dyeing properties. It is shown, that the 1,5- and 1,8- positions unfavourably influence the mordant-dyeing action. The introduction of the sulphonic acid group has a beneficial effect on the mordant-dyeing properties of hydroxyanthraquinones. It facilitates the formation of lakes, and is capable of acting as an auxochrome group. The sulphonic acids of quinizarin, xanthopurpurin, anthrarufin, chrysazin, and anthraflavic acid have been prepared and their dyeing properties investigated. In each case, the sulphonated compound was found to possess more powerful dyeing properties, the most striking instance being that furnished by anthrarufin, which having little or no dyeing action, is transformed into a real dyestuff by the introduction of the sulphonic acid group into its molecule.

—D. B.

Diazo-amino Compounds, Secondary —. L. Vignon and A. Simonet. Comptes rend., 1905, 140, 1038—1040.

The authors prepared a number of secondary diazoamino compounds by the action of diazo compounds on fatty and aromatic secondary amines, according to the equation.

The reaction takes place very easily if the diazo compounds from aniline, its substitution-products, the toluidines, or the naphthylamines are used. The reaction proceeds less easily with the xylidines and not at all with aromatic amino-acids. Sulphanilic acid gives, not the diazo-amino compound, but the corresponding azo derivative. Secondary diazoamines are unstable, with the exception of those derived from fatty secondary amines. The compound $\text{C}_6\text{H}_5\text{N}_2 \cdot \text{N}(\text{C}_2\text{H}_5)_2$ is a red oil, boiling at 258—240° C. which can, when dry, be distilled without decomposition. Secondary diazoamines can be converted into the corresponding azo compounds in presence of excess of an amine, which may be either primary or secondary. When heated with dilute acids they evolve nitrogen with formation of a phenol and the secondary amine, according to the equation:

In this reaction nothing corresponding to the migration of the hydrogen atom in the case of the primary diazoamines is observed when secondary diazoamines are used. All the diazoamines described are red to yellow substances, some of which could not be solidified but were obtained as thick oils. The compounds obtained by the action of diazo-benzene on monomethyl-, monoethyl- and monobenzylaniline, dibenzylamine, and diethylamine are described.—E. F.

ENGLISH PATENTS.

Amidothioaliphyl Derivatives; Manufacture of New —, and of New [Azo] Dyestuffs therefrom. O. Imray. London. From Soc. Chem. Industry in Basle, Basle, Switzerland. Eng. Pat. 7363, March 28, 1904.

Dyestuffs derived from Dyestuffs of the Oxazine Class: Manufacture of New — O. Imray, London. From Dye Works formerly L. Durand, Huguenin and Co., Basle, Switzerland. Eng. Pat. 3497, Feb. 20, 1905.

BLUE to yellowish-green dyestuffs are obtained by treating oxazines, especially galloxyanines and their derivatives with formaldehyde, in suitable neutral acid or alkaline media. The products can be used either for dyeing or printing. With chromium mordants greenish-blue to yellowish-green shades are obtained, very fast to light and to fulling. The best defined products are obtained by using equimolecular proportions of the oxazine and formaldehyde. For example, 37 kilos. of the galloxyaniline obtained from nitrosodimethylaniline and gallamic acid are dissolved in hot water, 12 kilos. of 40 per cent. formaldehyde added, and the whole heated to 100° C. for 10–12 hours, or until the liquid becomes plainly greenish. The product is then salted out. The above-described dyestuffs from oxazines and formaldehyde are converted into blue to green dyestuffs by heating with water to 100°–200° C. in presence or absence of acids. The products so obtained are more easily soluble in water than the original compounds. Their alkaline solutions also oxidise more rapidly in the air, and the tints obtained on dyeing or printing are bluer. On wool, with a chromium mordant, they yield greenish-blue shades. Dyestuffs of either of the above-described new classes are further modified by the action of acid, neutral or alkaline reducing agents. The products so obtained dye more evenly and yield bluer and brighter shades than the original compounds. An excess of reducing agent does no harm. Tin, zinc, aluminium, hydrosulphites and their formaldehyde compounds, alkali or hydrogen sulphides, titanium chloride or dextrose may all be used. The solutions of the products in water are oxidised by air. They dye wool from an acid bath, and other fibres when chrome-mordanted.—E. F.

Lakes; Manufacture of Colouring Matter — J. Y. Johnson. From Badische Anilin u. Soda Fabrik. Eng. Pat. 10,895, May 11, 1904. XIII. A., page 506.

UNITED STATES PATENTS.

Dyestuff, Anthracene, and Process of Making same; Violet — O. Bally, Mannheim, Assignor to Badische Anilin und Soda Fabrik, Ludwigshafen-on-Rhine, Germany. U.S. Pat. 786,085, March 28, 1905.

ON condensing β -aminoanthraquinone or its derivatives with glycerin in presence of sulphuric acid, compounds are obtained which dissolve in concentrated sulphuric acid to fluorescent solutions, and which yield dyestuffs similar to Indanthrene on melting with alkali hydroxide. The compound obtained from β -aminoanthraquinone gives a violet dyestuff on melting with alkali hydroxide.—T. F. B.

Dyestuff, Azo; Blue-Red — P. Julius and E. Fussenegger, Assignors to Badische Anilin und Soda Fabrik, Ludwigshafen-on-Rhine, Germany. U.S. Pat. 786,767, April 4, 1905.

ing Machine. H. W. Butterworth, Assignor to V. Butterworth and Sons, Co., Philadelphia. U.S. Pat. 786,264, April 4, 1905.

The invention relates to a mercerising machine, comprising a vat, a pair of pressure-rollers for applying tension to the fabric as it enters the machine, a series of vertical pressure-rollers geared together and having a line of contact below the level of liquid in the vat, squeezing-rollers arranged at a higher level for forcing the excess of liquid from the fabric as it leaves the machine. The distance between the pressure-rollers in the vat may be varied, and therefore also the extent of immersion of the fabric which is drawn through the rollers. The latter are carried on a pivoted frame which is journaled to the vat adjacent to the squeezing-rollers and is adjustably supported so as to vary the distance between the pressure-rollers in the fluid. Power devices are provided for positively rotating all the rollers at the same speeds, and tension devices for putting the fabric under tension immediately prior to its being drawn by the pressure-rollers.—B. N.

ing; [Electrically] Treating and Utilising — [Machine]. E. C. Paramore. U.S. Pat. 786,595, April 4, 1905. XI. A., page 503.

Carbon Emulsions; Preparation of —, and their Application for the Degreasing of Textiles. E. Saint-Ilre and E. de Grousseau. Fr. Pat. 348,501, Nov. 15, 1904. III., page 493.

Yarns; Degumming, Dyeing, Bleaching, &c. —. L. Détré. Fr. Pat. 348,368, Dec. 1, 1904.

The invention relates to the contraction of the fibre which occurs during degumming, dyeing, &c., of silk yarns, it has hitherto been impracticable to wind such yarns upon bobbins and treat them in this state with circulating dye, &c., in the manner frequently adopted with yarns of other fibres. To enable this to be accomplished, the silk yarns are wound upon the bobbins, simultaneously, and alternately in alternate layers with metallic wires, threads, or bands composed of fibres, e.g., cotton, which are not liable to contraction under the influence of the dye employed. Bobbins of silk yarns are thus obtained which remain permeable throughout the operation of degumming, &c., to which they are subjected.—E. B.

Impts. in Weighting —. A. Bussy. Fr. Pat. 348,291, Feb. 3, 1904.

The invention relates to a process for weighting silk by the use of tin salts. The silk is first impregnated with some soluble oil, which forms with certain metallic oleates on the fibre. It is then washed and treated through a solution of a salt of magnesium, iron, zinc, lead, barium, strontium or calcium. After washing, the metallic oleate on the fibre is converted into a phosphate or silicate by passing through an alkaline or silicate solution. These three operations are repeated as often as necessary to give the desired

amount of weighting, or the first two operations may be repeated several times, and the last performed once only.—T. F. B.

Logwood Black on Wool; Single Bath Method for Dyeing —. C. L. and J. Vandystadt. Fr. Pat. 348,283, Feb. 2, 1904.

The dye-bath employed is composed (for 100 kilos. of wool) of logwood (about 50 kilos.), fustic extract (2), ferrous sulphate (3), oxalic acid (2), common salt (9.75), sodium nitrate or nitrite (9.25), hydrochloric acid (1) and copper sulphate (1.75).—E. B.

Indigo and Analogous Compounds; Process for Reducing —. Badische Anilin und Soda Fabrik. Fr. Pat. 348,360, Nov. 29, 1904. Under Internat. Conv., Oct. 29, 1904.

It is found that indigo and its homologues and their derivatives may be reduced to indigo white by means of iron and alkali hydroxide solutions of strength not less than 10° B.; the reaction commences at a temperature of about 50° C. 250 kilos. of pure indigo are slowly added to a solution of 110 kilos. of caustic soda in 640 litres of water, containing 60 kilos. of iron dust, the mixture being heated to 75° C. A 30 per cent. solution of indigo white is obtained by filtering the reduced mixture *in vacuo*.—T. F. B.

Tissues or Paper; Coating — with a Layer of Artificial Silk —. L. Richard and J. Jacquin. Fr. Pat. 348,354, Nov. 29, 1904.

A thin sheet of polished metal, e.g., aluminium, or of any other flexible material not attacked by a solution of nitro-cellulose in a mixture of alcohol and ether, is passed through such a solution into a chamber, where the solvents are evaporated. The films thus obtained are denitrated, washed, rendered "incombustible," and dyed while adhering to the surfaces of the lamina upon which they have been formed. A dyed tissue, or a coloured sheet of paper is next fastened with gelatin to each side of the latter. The tissues, or the sheets of paper with the films adhering to them, are then detached from the metallic or other support. When a cotton tissue is employed, a fabric resembling it, it is stated, a tissue woven with a silk face and cotton back is produced.—E. B.

Colour Effects, Mixed, on [Raised] Tissues; Method and Apparatus for Producing —. C. Kübler. Fr. Pat. 348,398, Dec. 1, 1904.

A solution of a dyestuff or mordanting compound is supplied by furnishing rollers or by an endless travelling band to the revolving cards of a raising machine. From these it is transferred to a tissue, a nap being at the same time raised upon the surface of the latter by the action of the cards. The nap is thus dyed or mordanted for dyeing in a colour or colours different from that, or those, of the body of the tissue.—E. B.

VII.—ACIDS, ALKALIS, AND SALTS, AND NON-METALLIC ELEMENTS.

Hydrofluoric Acid II. (In Making Beet Sugar for the Removal of Rust from Iron, and in the Determination of Iron and Aluminium). E. Deussen. *Z. anorg. Chem.*, 1905, **44**, 408—430. (For Part I, see this J., 1905, 440.)

In the inversion experiments it was found that the direct polarimetric examination of solutions containing hydrofluoric acid was comparatively easy, especially if the closing plates for the polarisation-tube were made of fluor spar.

The inversion-constant of N 1 hydrofluoric acid is only 5.7 at 25° C., but is 22.26 at 35° C., and increases with rise of temperature. In the diffusion apparatus for the extraction of beet-juice, the temperature varies between 20° and 90° C., so that if hydrofluoric acid were added in sufficient quantity to exercise an efficient bactericidal effect, a not inconsiderable quantity of sucrose would be converted into invert sugar.

Verhieses' proposal to use hydrofluoric acid as an antiseptic in the manufacture of beet-sugar appears to hold out little prospect of success.

The author confirms Stahl's statement that commercial hydrofluoric acid is more efficient than hydrochloric or sulphuric acid in removing scale or rust from iron objects. If iron scale be treated with hydrofluoric acid, the scale being maintained in excess, a decrease in the amount of dissolved iron takes place after several hours' agitation, owing to the formation of a sparingly soluble iron oxyfluoride. A sparingly soluble copper oxyfluoride is formed in a similar manner.

For the determination of iron and aluminium in a strongly ignited mixture of a small proportion of ferric oxide with a large proportion of alumina, Hillebrand has recommended fusing with potassium pyrosulphate in a platinum crucible, dissolving in dilute sulphuric acid, precipitating the dissolved platinum by hydrogen sulphide, expelling the excess of hydrogen sulphide from the filtered solution by means of carbon dioxide, and titrating the iron with permanganate. The author finds that the fusion can be completed in a few minutes, and without the platinum being attacked, if potassium hydrogen fluoride, K.F.H., be used in place of potassium pyrosulphate. The titration with permanganate is, however, inaccurate in presence of any considerable quantity of free hydrofluoric acid, so that, after the fusion, the greater portion of this acid must be expelled by heating with dilute sulphuric acid. The solution of the sulphates is then reduced with sulphurous acid, the excess of the latter expelled by means of carbon dioxide, and the iron titrated with permanganate.—A. S.

Ammonia; Decomposition of — at High Temperatures. A. B. White and W. Melville. *J. Amer. Chem. Soc.*, 1905, **27**, 373—386.

The temperature of initial decomposition of ammonia is found to be about 450° C. The amount of decomposition when passed through a hot tube, is not affected by dilution with an inert gas such as hydrogen or nitrogen, providing the rate of flow of the gas through the tube remain the same. This confirms the work of Deville and Troost (*Comptes rend.*, **56**, 895), and of Perman and Atkinson (this J., 1904, 915). The introduction of carbon monoxide and of aqueous vapour increases the rate of decomposition somewhat. The formation of cyanogen was small. The observations of Ramsay and Young (this J., 1884, 157) as to the influence of the nature of the hot surface on the rate of decomposition of the ammonia, are fully confirmed. It is concluded that, in the destructive distillation of coal, decomposition of the ammonia may be diminished by keeping the temperature low, and by diminishing as far as possible the duration of contact of the hot gases with rough substances such as the coke or retort. The high yield of ammonia in the Mond gas process is attributed to the lower temperature of working and to the rapid removal of the gases.—T. F. B.

Hydrosulphites (Hyposulphites); Preparation of Bility. *Comptes rend.*, 1905, **140**, 936—937.

The author finds that the production of sodium hydrosulphite according to the Badische Co.'s process by action of sulphur dioxide upon sodium (this J., 1903, only takes place in presence of absolute alcohol, and in presence of ether as stated. This reaction depends on the presence of some solvent which is attacked by metal. Magnesium hydrosulphite is formed by the action of dry sulphur dioxide upon magnesium in presence of absolute alcohol. The hydrosulphite is soluble in absolute alcohol, in the form of an acid salt, in presence of excess of sulphur dioxide, but is deposited when the excess of the latter is removed *in vacuo*. When the solution is evaporated to dryness in the cold, a double compound of magnesium hydrosulphite and alcohol, insoluble in absolute alcohol, is obtained. The mechanism of the reaction is explained by the observation that magnesium is capable of combining with alcohol to form an alcoholate evolution of hydrogen. The latter forms magnesium hydride which reacts with the sulphur dioxide. Calcium, aluminium, and iron also form hydrosulphites slowly at ordinary temperatures when sealed up in presence with alcohol saturated with sulphur dioxide.—J. F.

Hydrofluosilicic Acid; Behaviour of — to Various Reagents. A. Gawalowski. *XXIII.*, page 513.

ENGLISH PATENTS.

Sulphuric Anhydride; Apparatus for the Manufacture of — [by the Contact Process]. G. Eschellner, Harpmuth, and the Tov Tentelevskago Xim Zavoda, St. Petersburg. Eng. Pat. 20,952, Sept. 1904.

SEE Addition, dated Oct. 4, 1904, to Fr. Pat. 321,500, May 20, 1902; this J., 1905, 277.—E. S.

Sodium Perborate; Process of Preparing —. Deutsches Gold und Silber-Scheide-Anstalt vorm. Rössler. Fr. Pat. 348,456, Oct. 14, 1904.

SEE Eng. Pat. 22,004 of 1904; this J., 1905, 197.—T. F. B.

Vanadium; Treatment of the Ores of —, by the Bisulphates. A. H. Perret. Fr. Pat. 348,633, Mar. 1904.

The ores are treated with a fused alkali bisulphate and the mass is further heated to set free sulphuric anhydride, which is collected. The residue is exhausted with water, and to the filtered solution, ammonium chloride is added. The precipitate is collected and calcined to obtain crude vanadic anhydride.—E. S.

Oxygen and Nitrogen from Liquid Air; Process of Separation of —. Société pour l'Exploitation des Procédés Georges Claude. Second Addition, Feb. 12, 1904, to Fr. Pat. 328,245, of Jan. 3, 1900 (this J., 1903, 950).

In the process described in the main patent for the separation of oxygen and nitrogen by partial liquefaction with backward return of the liquid formed, it is now proposed that two or more such returns may be made, with an adjustment of the intervening pressures. Arrangements are made for maintaining a partial vacuum, in order to reduce the degree of compression required for the liquefaction of the gas. The tubular system in which the process is carried out, consists of a series of vertical

versing a number of vessels, in which the liquid air is by overflow tubes successively from vessel to vessel, whereby a methodical application is made of the principle of the partial liquefaction of air with backward return. (Also First Addition, dated June 5, 1903, to the same Pat.; this J., 1903, 1292.)—E. S.

GERMAN PATENTS.

Nitric Acid; Process for the Preparation of — H. H. Nidenführ. Ger. Pat. 155,095, May 29, 1903.

It is made for the placing of a draught-producing ice between the condensing apparatus for the nitric vapours, connected directly to the still, and a filter apparatus intended for the oxidation and condensation of the lower oxides of nitrogen. The gases are entering the last-mentioned part of the plant, or are entering the draught-producing device, may be led. The process is worked in such a manner that a moderate vacuum is maintained in the condensing apparatus for the nitric acid, whilst that portion of the plant which is beyond the draught-producing device, and which of smaller dimensions, is kept under a slight pressure. It is stated that the condensing apparatus for the nitric acid can be maintained at a temperature so high that nitric acid readily gives off any oxides of nitrogen it contains, so that the strongest commercially pure acid is obtained in this portion of the plant.—A. S.

Nitric Acid; Method for the Purification of — by Distillation. J. Waldhauer. Ger. Pat. 155,006, Dec. 1, 1902.

Nitric acid is purified by distillation in iron vessels heated externally. The stills are filled with granular material to which the acid is allowed to flow, the rate of supply being so regulated that as the acid traverses the granular material, it is evaporated, and only vapour comes in contact with the walls of the still. In packing the still it is preferable to use a layer of fine sand next to the walls, a layer of coarse sand, and in the centre, a core of iron on to which the acid is allowed to flow.—A. S.

Ammonium Potassium-Magnesium Carbonate — Salzbergwerk Leuzstätt. Ger. Pat. 155,007, May 2, 1901. Addition to Ger. Pat. 143,409 of April 13, 1900 (this J., 1903, 949).

The decomposition of the potassium-magnesium carbonate effected in closed vessels, so that the magnesium carbonate trihydrate is formed in presence of carbon dioxide, is stated that by preventing the escape of carbon dioxide, the conversion of the crystalline magnesium carbonate trihydrate into amorphous salts containing less water of hydration is avoided, and that the temperature at which the decomposition is effected can be raised from 100°C., which is given as the upper limit in the main patent, up to the boiling point.—A. S.

Zinc Chloride Solutions; Method of Enriching — L. Jöppner. Ger. Pat. 155,065, May 1, 1902.

Zinc sulphite and lead chloride are dissolved in a hot dilute solution of zinc chloride, whereby the lead is precipitated as sulphite, whilst the zinc goes into solution as chloride. A dilute zinc chloride solution is obtained in several processes for the lixiviation of zinc ores, the zinc sulphite produced when zinc ores are extracted with sulphurous acid, and the lead chloride is obtained by the treatment of ores containing lead with chlorine and certain chlorides.—A. S.

III.—GLASS, POTTERY, AND ENAMELS.

Coloration of — by Natural Solar and other Radiations. W. Crookes. Proc. Roy. Soc., 1905, 74, 524—528.

Two samples of glass coloured an intense purple by the action of light are described. Both samples were originally white, and became coloured by exposure to the sun's rays, one at Uyuni, in Bolivia; the other at Iquique, in

Chile. It was found that both samples contain manganese, and that the colour could be discharged by heating them to their softening points in covered crucibles. The bleached glass speedily became coloured again on exposure to radium rays. The colour is probably due to the manganous compounds in the glass being converted into manganic salts at the expense of the oxygen of the ferric salts present, under the influence of intense solar radiation. The author believes that the high altitude at which both samples of glass were exposed, has some influence on the phenomenon, in that it allows of many rays, which would otherwise be absorbed by the atmosphere, to act on the glass. Judd, on the other hand, points out that green glass at the low elevation of Kew, in time becomes first colourless and then purple; the original green colour is due to ferric oxide, and manganese is always present.

—A. G. L.

Colours, Lead [Pottery]; Non-Poisonous Fusible — E. Berdel. Sprechsaal, 1905, 38, 345—346; 393—395; 438—440.

Attempts made to replace part of the alkali and lead by zinc and bismuth were unsuccessful, the products being poisonous. The following fluxes, however, proved able to withstand the German test for non-poisonous lead glazes, namely, that the solution obtained by boiling the glaze for half an hour in a 4 per cent. solution of glacial acetic acid shall not give any precipitate with sulphuretted hydrogen.

Calcined sodium carbonate 10.6—31.8 parts, Norwegian feldspar 83.4, red lead 114—171, quartz 96—99, crystallised boric acid 49.6—55.8 parts. The resulting glazes fuse at Seger cone 022—020.

Calcined sodium carbonate 10.6—15.9 parts, Norwegian feldspar 83.4, red lead 136.8—148.2, barium carbonate 19.7, quartz 90—99, crystallised boric acid 49.6—62.0 parts. These fluxes are not quite so soft as those of the first group, but fuse at Seger cone 020—018.

Red lead 182.4—205.2 parts, barium carbonate 19.7—39.4, burnt Zettlitz kaolin 33.3, quartz 132.0, crystallised boric acid 49.6 parts. The omission of alkali gave higher fusion temperatures, viz., Seger cone 015.

Red lead 193.8—205.2 parts, barium carbonate 19.7—29.5, burnt Zettlitz kaolin 11.1, quartz 177.0, crystallised boric acid 49.6 parts. The still higher fusing point of this group (Seger cone 05) renders it unsuitable for ordinary fusible colours.

For purple, 4.5 per cent. of 15 per cent. gold purple was employed, with the foregoing fluxes, the more fusible mixtures being fritted at Seger cone 019 and the finished colour fired on the porcelain at cone 017. With the less fusible fluxes the corresponding temperatures were cones 015 and 014 respectively. The resulting fine red stood the test in all cases.

For yellowish red to salmon-red colours, three parts of flux were mixed with one of a pigment consisting of chromic oxide 25.5 parts, alumina 17.0, ferric oxide 26.7 and zinc oxide 40.5 parts (fired at cone 9 in an oxidising atmosphere, ground and washed). The frit was prepared at the temperature of cone 019, and the colour fired on the ware at cone 017 for the first two groups of fluxes, and 014 for the others. No trace of lead could be extracted under the conditions of the test.

The pigment for black was compounded of chromic oxide 76.5 parts, cobalt oxide 18.0, ferric oxide 12.0, manganese oxide 3.8, and nickel oxide 6 parts, triturated, and fired in the hottest part of the porcelain kiln, in a reducing atmosphere. The best results were obtained with one part of pigment to four of flux, the fritting and firing being the same as for the other colours mentioned. These colours also stood the test perfectly.

For green the pigment consisted of 76.5 parts of chromic oxide and 51 of alumina, fired as in the case of black. Mixed with flux, the colour proved more readily fusible than its composition indicated. No lead could be extracted from the fired mixtures of one part of pigment to three, four and five parts of flux respectively. The smallest proportion of flux gave a matt surface, the next a handsome lustrous green, and the other a lustrous but somewhat lighter shade. The fritting temperatures for the fusible and refractory fluxes were

cone 019 and 015, and the firing temperatures 017 and 014.

To obtain the pigment for blue, 51 parts of alumina were mixed with 61 of cobalt phosphate, ground, and fired in the hottest part of the porcelain kiln. With three parts of flux to one of pigment, a matt colour was obtained, which on testing gave a blackish precipitate, consisting mainly of cobalt sulphide. Increasing the proportion of flux to five parts, on the other hand, led to the solution of the cobalt oxide and a total loss of tone. The best results were obtained with $4\frac{1}{2}$ parts of flux, fritted and fired at the same temperatures as for green, the colour being a beautiful, deep, lustrous blue yielding no trace of a lead precipitate under the test.—C. S.

Tungstic Anhydride as a Ceramic Colouring Agent; Properties of —. A. Granger. *Comptes rend.*, 1905, 140, 935—936.

The difficulty hitherto experienced in utilising tungstic anhydride as a yellow colouring agent in ceramics has been the tendency shown by the coloured glazes to become opalescent or opaque on firing. Lead glazes and baryta glazes generally show this defect when mixed with tungstic anhydride, but with suitable mixtures it is quite possible to prepare such glazes perfectly transparent. For instance, to a glaze of the general formula $\text{MO} \cdot 2\text{SiO}_2$, 0.1 mol. of alumina was added; 0.5 mol. of silica was then replaced by boric anhydride, and a further 0.1 mol. of silica was replaced by tungstic anhydride. The bases employed were soda, lime and lead oxide in the ratios $\text{Na}_2\text{O}:\text{CaO}:2\text{PbO}$. The basic glaze so produced was readily fusible and quite transparent; it had a yellowish colour. A glaze with similar properties was also prepared by replacing the lead oxide by baryta. A glaze of this nature, however, became opaque on firing, when the proportions of alumina and silica were increased by about one-third.—J. F. B.

ENGLISH PATENTS.

Quartz Glass; Manufacture of —. J. Y. Johnson, London. From W. C. Heraeus, Hanau, Germany. Eng. Pat. 3906, Feb. 24, 1905.

To avoid formation of air-bubbles in the fused glass, pieces of rock-crystal, ranging in size from that of a hazelnut to that of a walnut, are very slowly and carefully heated to a temperature of 600° C., and then, piece by piece, at once subjected to a vitrifying temperature, either in an oxyhydrogen blow-pipe flame or else in a furnace. In the first case, the vitrified pieces must be separately stove; in the second case, each piece must be allowed to fuse and unite completely with the main mass before the next piece is introduced.—A. G. L.

Quartz Glass; Moulding Hollow Vessels of —. J. Y. Johnson, London. From W. C. Heraeus, Hanau, Germany. Eng. Pat. 4663, March 6, 1905.

A THICK-WALLED cylinder closed at one end is first obtained, either by drilling a hole into a cylindrical piece of quartz glass, or else by forcing a piece of softened quartz glass into a cylindrical mould by means of a plunger having a conical projection. The open end of this cylinder is then attached to a tube of quartz glass, after which the cylinder is further worked as usual in the blow-pipe flame.—A. G. L.

Glass; Process and Apparatus for the Manufacture of —. S. O. Richardson, jun., Toledo, U.S.A. Eng. Pat. 9776, April 28, 1904.

SEE U.S. Pat. 766,771 of 1904; this J., 1904, 866.—T. F. B.

UNITED STATES PATENT.

Furnace; Glass-Melting —. E. Baudoux, Genappe, Belgium. U.S. Pat. 787,553, April 18, 1905.

SEE Eng. Pat. 19,067 of 1904; this J., 1905, 91.—T. F. B.

FRENCH PATENTS.

Glass; Manufacture of Transparent —. G. Hall. Fr. Pat. 347,897, Nov. 14, 1904.

To obtain a determined degree of tenuity in the covering on the glass, the covering itself having been applied by the usual process described in the specifications well-known, the excess of the metal is removed by treatment with an acid solution of known strength, which is allowed to act for a definite time.—A. G. L.

Ceramic Objects of Art; Manufacture of —. S. St. Fr. Pat. 348,061, Oct. 1, 1904.

WELL-WASHED clay is moulded to the desired form. The objects are partly dried and polished with oiled plates. The drying is then completed, after which the articles are burnt in a closed muffle, and exposed to a smoky flame, and after cooling, are rubbed with wax. To impart a different colour, the articles may, after first burning, be again heated after bedding them in shavings in a closed muffle, the cooled articles being then exposed to the action of a very smoky flame, cooled, polished with wax. A design in relief may also be produced on the burnt articles, the design being then covered with well-washed clay, dried, and burnt, using a smoky flame. After cooling, the covering clay is removed, when the design will show in the original colour of the clay.—A. G.

Pottery; Application to Culinary — of Ceramic Enamel of all Colours, Transparent or Opaque; and Application below or on top of these Enamels of Ornamentation of all Colours. L. J. Boissonnet. Fr. Pat. 347,000, Oct. 31, 1904.

The articles are made as usual of pure clay, burnt at 990° C. They are then covered with a layer of potassium silicate, and steamed, to give hardness to the enamel. The design is then produced on them as usual, different metallic oxides, mixed with gum, being used for the different colours, after which the enamel is applied in a suitable composition for this is as follows: Borax 90 parts; boric acid, 20; silica, 5; porcelain glaze, 5; calcium carbonate, 30. To produce a coloured enamel, 80 parts of this are mixed with 20 of a coloured metallic oxide; for an opaque enamel, 2 per cent. of zinc oxide is added. The whole is then again burnt, gently for the first 12 hours, and then for 18 hours at about 1100° C., and is allowed to cool for 72 hours.—A. G. L.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

Cement, Portland; Spontaneous Decomposition of Calcium Silicates; and the connection between Felite and Portland Cement in —. H. Kappen. *Tonind. Zeit.*, 1905, 9, 370—373.

IN mixtures of limestone and blast-furnace slag the clinker has a tendency to disintegrate spontaneously with proportions of silica over 24 per cent.; and the chief constituent of the disintegrated mass is felite, although Törnebohm regarded belite (the hydraulic modification of bicalcium silicate) as the prime cause of the phenomenon. On examining granulated blast-furnace slag, it is found to consist chiefly of gehlenite (a calcium aluminium silicate) and felite, the former crystallising out while the mass is still fluid, whereas the crystallisation of felite does not begin until the mass is apparently solid, the result being that the liberation of heat due to the sudden expansion produces disintegration. As the constituents of felite are present in the same proportions of solution in cement clinker is shown by the fact that crystals of spinel are found therein, embedded in the granules. The author has found that felite consists of a non-hydraulic modification of bicalcium silicate, and that its predominance in blast-furnace slag precludes the possibility of obtaining a useful cement from that material, unless mixed with an alkaline adjunct, such as Portland cement, Roman cement, &c.

Owing to its relatively low sp. gr. (always below 3.0) felite, when present, falsifies the result of the determination of light substances in cement by means of methylene

proportion of belite to felite in cement clinker on the kiln temperature employed, a low temperature favouring the production of belite, whilst felite is increased when higher temperatures are used. Thus the same mixture will give a large proportion of belite fired in a ring kiln, but felite alone when fired in the rotary kiln. In the latter case, however, the cement is protected from disintegration by the influence of the rapid firing, which both retards the development of the felite and minimises the expansion. On the other hand, cement materials be imperfectly mixed, the resulting mass will burst, even though only the central portion has gone disintegration in cooling. Pure bicalcium silicate, prepared by prolonged heating to incipient fusion, or actual fusion, disintegrates on cooling, the resulting powder consisting entirely of felite.

The difficulty in the way of producing the hydraulic cement, belite, is due to the fact that the difference between its fusing point and crystallisation point is very small; and when the belite crystals have been destroyed by fusion, they do not re-form, but are replaced by felite.

Stones; New Method for the Determination of Magnesium Carbonate in —. W. F. Koppeschaar. *Anal. Chem.*, page 613.

Alcohol in Portland Cement; Alkaline Reaction of Free —. *Absolute Alcohol*. E. Drexel. *XXIII.*, page 613.

ENGLISH PATENTS.

Manufacture of —. S. McFarlane, Leeds. Eng. Pat. 6631, March 18, 1904.

A mixture of white Portland cement and calespar is moulded and consolidated, after which the surface of the mass is polished by passing over it first an iron plough or bar, and then a specially prepared steel plough or bar having a highly polished face. Lampblack or colouring matter may be added to the mixture.

—A. G. L.

Glazing Matter and the like on Tiles, Brick and other Articles; Machine for Applying —. E. Goldsmith, Middletown, Ohio. Eng. Pat. 8619, April 14, 1904.

A glazing matter or the like is raised from a container by a rotating cylinder, and then transferred to a transferer, e.g., a rotating cylinder, for application to the brick or other article. The cylinder does not touch the drum, but dips into a collection of the matter set up in a shallow container formed by a wedge-shaped wiper behind the drum and sweeps back the material. To assist the action of this wiper, a roller may be placed close to it in contact with the drum, so as to keep the descending side of the latter clean. The transferer cylinder is preferably provided with an absorbent surface, e.g., felt or sponge-rubber, and covered by wire-gauze. To avoid difficulties caused by irregularities of speed, a second wire-gauze envelope may be freely placed over the first. In another form of cylinder, it is provided with longitudinal grooves covered by wire-gauze, over which is placed a layer of bent material, and then another envelope of wire-gauze, so as to allow any air-bubbles to escape inwards through the grooves. —A. G. L.

Insulating Materials, Heat Insulating Materials and the like; Manufacture of —. H. H. Lake, London. Eng. Pat. 9680, April 27, 1904.

Slag is mixed with readily combustible materials, such as little ash, such as cork or chaff, silicated clay, water-glass and silicated magnesia, obtained by solution from a magnesium salt solution, are added. The mixture may be added an acid for separating silicic acid, but generally this may be omitted, the carbon dioxide being evolved during the subsequent firing functioning as the gas. After the mixture has dried in the air, it is moulded into building stones and the like, and burnt to a sintering temperature. The soluble salts may then be removed by lixiviating. A suitable composition is the following: Kieselsäure, 170 lb.; clay, 40; cork, 110; water-glass, 9; and magnesium chloride, 9. —A. G. L.

Bricks; Impts. in —. J. T. South, Brighton, Eng. Pat. 9706, April 28, 1904.

The brick is made by mixing and moulding with water, Portland or other cement, coal ash or sand or grit, alum or "dissolved flint" (i.e., a solution of ordinary flint in hydrofluoric acid), or copperas or green vitriol, or carbon and "soda" in equal parts, and a suitable pigment. After removal from the moulds, the bricks are stacked with free access of air until "matured," which requires about 14 days. Suitable proportions are (1), Portland cement, 5 cwt.; coal ash or sand or grit, 30 cwt.; chalk, 9 cwt.; dissolved flint, 14 lb.; a suitable pigment. (2), Portland cement, 5 cwt.; coal ash, 30 cwt.; chalk, 6 cwt.; sand, 3 cwt.; alum or copperas, 2 lb.; a suitable pigment. (3), Portland cement, 5 cwt.; coal ash or sand or grit, 30 cwt.; chalk, 9 cwt.; carbon, 1 lb.; "soda," 1 lb.; a suitable pigment. —A. G. L.

Varnishes and Paints for Waterproofing, Disinfecting and other Purposes, also for Indurating Building Materials; Manufacture of —. J. Hargreaves, Eng. Pat. 11,398, May 18, 1904. *XIII. A.*, page 506.

Plaster; Process of Treating Gypsum to obtain, as desired, a Slow or Quick-Setting —. L. Périn. Fr. Pat. 348,104, Nov. 10, 1904.

In order to obtain a plaster with any required rate of setting, a fixed weight of gypsum is treated in a cylinder, with heat derived from a furnace or producer yielding a constant amount of heat in unit of time, for a definite time depending upon the hygrometric state and on the hydrate to be obtained, whereby a product is obtained intermediate between the gypsum with two molecules of water and the anhydrous calcium sulphate, the amount of water of crystallisation in the product determining the rate of setting. —W. C. H.

Plaster; Manufacture of Articles by Agglomeration of Coarse or Fresh — by Pressure and without Mixing. E. M. Panpy, né Vignaudon. Fr. Pat. 348,236, Nov. 24, 1904.

COARSE or refuse plaster, either with fresh, or a mixture of fresh and old plaster, is consolidated, in a slightly moist condition, with or without the addition of other bodies, by strong pressure and without the ordinary mixing. The claims also include products thus obtained.

—W. C. H.

Building Materials; Refractory —. E. Hachon—Doucet. Fr. Pat. 347,880, Nov. 12, 1904.

BLAST furnace-slag, preferably finely ground, is mixed with argillaceous materials and burnt, the product obtained being used like cement. —A. G. L.

Stone; Manufacture of Artificial —. J. Staudt. Fr. Pat. 348,601, Dec. 6, 1904.

MATERIALS, such as chalk, quartz, clay, &c., are

powdered and mixed with drying or other oils, fats, wax, &c., the admixture being aided by adding a volatile solvent if necessary. The mixture is thickened by heating at a temperature varying from 60° to 140° C., in a current of air, and is then exposed to the action of the air, when it falls to a light powder, which is moulded under pressure, and heated for 12 to 24 hours at a temperature of 120° to 180° C.—A. G. L.

CRYSTALLISED magnesium chloride is heated, with evolution of hydrochloric acid, until a mixture of magnesia and magnesium chloride in the desired proportions is obtained.—A. S.

X.—METALLURGY.

Gold; Effect of Silver on the Chlorination and Bromination of —. H. O. Hofman and M. G. Magnuson. Bull. Amer. Inst. Mining Eng., 1905 [2], 421—433.

EXPERIMENTS were made to ascertain the relative solv action of chlorine-water and bromine-water on gold alloys of gold and silver. The charge consisted of 5 ass. tons of the ore (a mixture of 5 A.-T. of quartzite crushed to 40-mesh size with 10 mgrms. of the gold or gold-silver alloy in the state of fine powder), 150 c.c. of water, and varying quantities of chlorine (bleaching powder or sulphuric acid) or bromine; and the time of extract was 5½ hours. With pure gold, solutions containing 2.1 and 1.4 grms. of chlorine gave extractions of 99.8-6, and 92.5 per cent. respectively of the gold. These results confirm those obtained in practice, and show that a satisfactory extraction of gold by the barrel-chlorination process can only be attained by the use of supersaturated solutions of chlorine, the degree of supersaturation required varying with the character of the ore. A solution containing 2.8 grms. of chlorine extracted a satisfactory proportion of gold from gold-silver alloys containing as much as 20 per cent. of silver, but with decrease of chlorine below a certain amount (2.1 gm.) and the increase of silver above 10 per cent., the percentage of gold extracted diminished rapidly. With bromine, solutions containing 8.97, 5.98, 4.48, 2.90, 2.60 grms. gave extractions of 99.8, 98.2, 96.6, 93.2, 92.2 per cent. respectively of gold. The proportion of gold extracted from gold-silver alloys containing 20 per cent. of silver was not more than 1 per cent. less than from pure gold with solutions containing 8.97, 5.98, 4.48, 2.90 grms. of bromine, but with 2.6 grms. of bromine extraction was only 77.6 per cent. as against 92.2 per cent. from pure gold. With an alloy containing 30 per cent. of silver, the solution containing 8.97 grms. of bromine extracted 97.7 per cent. of the gold, whereas the strongest solution of chlorine (2.8 grms.) only dissolved 40.3 per cent. The comparative solvent action of chlorine and of bromine on gold and gold-silver alloys is shown in the curve diagram (see Fig.); on the whole, bromine appears to be the more efficient solvent.—A. S.

Gold Bullion and Cyanide Precipitates; Refining — with Oxygen Gas. T. Kirke Rose. Inst. of Mining Metall., April 13, 1905.

THE results of a large number of experiments, which set out in detail, show that base metals can be removed from gold and silver bullion by the passage of a current of oxygen or air. Losses due to volatilisation and spir

significant, and those due to the slag can be kept stopping the process before the refining is complete. Fluxes required are borax and silica, and a slag of the composition $\frac{2}{3}(\text{Na}_2\text{O} \cdot \text{B}_2\text{O}_3) + 6\text{RO} \cdot \frac{1}{3}(\text{B}_2\text{O}_3)$ appears to fulfil requirements except that of cheapness. If 20 per cent. of the borax and the silica in the flux be omitted, the slag becomes somewhat pasty, but it is probable that as 90 per cent. of the borax could be replaced by silica. Most of the gold in the slag can be recovered by concentration, but the silver cannot be obtained in this way. The greater part of the valuable metals in the slags recovered by fusion with carbon and iron, the lead being reduced, and carrying down the gold and silver. The cost of treatment by air appears to be less than by other refining processes, but it is necessary to estimate the relative losses on the working scale. The method would appear to be very suitable for the treatment of zinc-box precipitates, from which a portion of the lead has been separated previously by volatilisation, in order to save fluxes and to avoid pasty slags.—A. S.

of Copper and Bismuth A. H. Hiorns. Paper read before the Faraday Society, April 4, 1905.

Experiments were carried out like those on copper-alloys (this J., 1904, 547). At the extremes are pure copper and pure bismuth, intermediate are solutions of bismuth in copper and copper in bismuth. The eutectic points occur at 243° C. and 1020° C.; there is a congruent point (between solutions of copper in bismuth and bismuth in copper) at 858° C. As the proportion of bismuth rises from 30 to 43 per cent. there is practically no change in the freezing-point; no indication exists of the formation of the two compounds here possible (Cu_3Bi_2 and Cu_2Bi), which are isomorphous with bismuth. Copper in small percentages of bismuth consists of polygonal grains bounded by a thin line of bismuthide, along which the eutectic occurs. At 2 per cent. of bismuth a eutectic structure is shown, and as the bismuth increases, the graininess is widened, and the interior is eutectic in character. At 10 per cent. of bismuth the whole surface is composed of the two solutions, light grey and light red, and at 67 per cent. a set of dark blue grains (perhaps Cu_3Bi_2) appears in addition. At 70–90 per cent. the red solution is seen as a eutectic; at 97.2 per cent. the surface is eutectic, and from 98 per cent. onwards the structure is that of bismuth.—J. T. D.

for Furnaces; Refractory Materials for —. Gilbert Scott. Paper read before the Faraday Society, April 4, 1905.

REFRACTORY material must—1. Conduct heat badly; 2. be mechanically strong over a wide range of temperature; 3. withstand the reducing action of the atmosphere, especially of carbon; 4. be a non-conductor of electricity even at high temperatures, if to be used in an electric furnace.

The author classifies refractory materials in four groups, the first two with the second and third groups:—

Carbon.—For the highest temperatures.

Silicon Carbides.—*a. Carborundum*.—An excellent refractory; binding material sodium silicate or fire-clay. *b. Siloxicon*.—Almost self-binding, but it is well to use alumina or non-alkaline clay for making up articles which are to be baked before use, or sodium silicate or coal-tar pitch. It is very refractory, chemically inert, and does not soften at 3000° C., forming silicon carbide. *c. Silico-graphite*.—Conducts heat rather well, but is suitable only as a wash, binding with glue, or as a silicate or tar.

Crystallised Magnesite.—Ordinary calcined magnesite is the best material for basic open-hearth furnaces and cement kilns, being free from moisture and resistant to corrosion. By charging magnesite into an ordinary calcium carbide furnace, thoroughly crystallised magnesite can be obtained; 300 h.p. for 24 hours yielded 3 cwt. This, used as a wash over the brick lining of a calcium carbide furnace,

lengthened the life of the bricks before repairs were needed from 5 to 200 hours.

4. Ordinary Fire-bricks.—For the lower range of furnace temperatures.—J. T. D.

Hydrofluoric Acid (Use of — for the Removal of Rust from Iron, &c.) E. Deussen. VII., page 496.

Steel; Manufacture of —, by the Basic Bessemer Process. O. Massenez, Wiesbaden. Eng. Pat. 19,053, Sept. 3, 1904.

CERTAIN disadvantages in the ordinary process are obviated by adding to the molten pig-iron in the converter, lime or oxides of iron or manganese, or mixtures of the same, with or without addition of fluor-spar or other fluxes. The first formed slag, which contains very little phosphoric acid, having been removed, a further quantity of lime is added, amounting to about 10 per cent. by weight of the charge, which takes up all the phosphoric acid. By this process, pig iron containing more than 1 per cent. of silica and less than 1.8 per cent. of phosphorus may be advantageously treated.—J. H. C.

Slimes, Gold-bearing; Apparatus for the Separation of Liquids from Solids, particularly applicable to the Treatment of —. R. K. Evans, London. Eng. Pat. 3962, Feb. 17, 1904.

EACH filtering element consists of a shallow box *a*, provided with a perforated plate *b*, on which the filtering medium is laid, the plate *b* being supported by the bars *c* and kept in position by the grids *d*. The boxes are arranged so as to form an endless band having rollers *e* adapted to run on the tracks *f* and *g*, and moved forward in the direction of the arrows, at a low speed by the wheels *h*, *h*. The gold-bearing slimes are fed from the shoot *u* on to the surface of the filtering medium, and as the boxes move forward, suction is applied to the interior by the pipes *j*¹, controlled by the valves *j*, which are opened by the projection *t*. The pipes *j*¹ are connected together by the branches *k* and the flexible pipes *k*¹. At one point the pipe *k* is attached to a flexible tube *l*, coiled round the spring drum *m*, and communicating through the joint *n* and the pipe *o* with the exhausting apparatus. The object of the spring drum *m* is to allow the connection *l* to be varied in length to suit the position of the joint with *k*, as the band moves round the track. The suction draws the liquid in the slimes through the filter into the box, and when the latter has travelled further towards the left, the valve *j* is shut by the projection *t*¹ and the liquid is discharged, through the pipe *p*, which has hitherto been closed by the flap valve *q* (Fig. 4) held up by the vacuum in the box, into the trough *r*, and it flows away by the pipe *s*. Washing water can then be run on to the residue through the pipe *r*¹, and passes through it into the box *a*, and away by the second compartment of the trough *r*² and the pipe *s*¹. When the filter-box *a* arrives opposite the shute *v*, the washed deposit is discharged, and in order to facilitate this, a regulated charge of compressed

air may be delivered behind the deposit by a similar series of pipes to j , j' , k , which serve to apply the vacuum, but placed on the opposite side of the box a , and not shown in the figures.

A modification of the apparatus is described in which the use of flexible connecting pipes is avoided.—W. H. C.

Furnace applicable for use in Roasting Ores and for other Purposes; Rotary —. F. Heberlein, London, and W. Hommel, Lee, Kent. Eng. Pat. 10,682, May 9, 1904.

SEE U.S. Pat. 781,824 of 1905; this J., 1905, 242.—T.F.B.

UNITED STATES PATENTS.

Furnace; Roasting —. W. R. Ingalls, Lynn, Mass. U.S. Pat. 786,567, April 4, 1905.

THE furnace has two or more superposed hearths and a system of flues placed beneath the hearths in which gas

is burnt, so that the products of combustion circulate throughout the system. The rotary stirring apparatus consists of a central vertical shaft and a series of horizontal arms, all being made hollow, so that a cooling medium may circulate throughout the system.—J. H. C.

Furnace; Roasting —. C. H. Repath and F. E. Repath, Assignors to F. Klepetko, New York. U.S. Pat. 786,599, April 4, 1905.

IN a furnace having a number of superposed hearths, a fire-chamber is arranged beneath the bottom hearth, the series, and independent flues, provided with controllable dampers, and located within the walls of the furnace lead from the fire-chamber to the several hearths. A central hollow stirring shaft passes through the furnace and carries hollow arms which extend into the hearths, these arms being provided with openings for delivering air to the hearths during the roasting operation.—A.

THE electrolyte consists of a solution of a haloid salt of zinc, preferably the bromide, which is decomposed during the charging, the metal being deposited on the negative pole of zinc, whilst the bromine, liberated at the carbon electrode, dissolves in the liquid. During the time of discharging, the haloid salt is re-formed. A partition, reaching nearly to the top of the vessel, divides the latter into two compartments in one of which the electrodes are placed. By placing the vessel on its side, the liquid may be poured into the vacant compartment, and the

electrolyte is thus placed out of contact with the electrodes during the period of inactivity of the accumulator.—B. N.

GERMAN PATENT.

Electrodes for Accumulators; Process for the Preparation of Positive —. R. Getze. Ger. Pat. 155,105, June 13, 1902.

THE preparation of positive electrodes for accumulators by forming a layer of spongy lead electrolytically from lead peroxide, is carried out in a solution of a salt such as zinc sulphate. The layer of spongy lead produced becomes impregnated with this solution, and on drying, the salt is left behind in a state of fine division between the particles of lead, whereby, it is stated, the electrode may be kept for a long time in the dry state without losing its activity.—A. S.

(B).—ELECTRO-METALLURGY.

Metals of the Alkalies and Alkaline-Earths; Position of the — in the Potential Series at High Temperatures. H. Danel and L. Stockem. Z. Elektrochem, 1905, 11, 209–211.

IS the electrolytic separation of metals it is often desirable to work at as low a temperature as possible, when such disadvantages as volatilisation of the metal, destruction of plant, &c., are partially obviated. To effect this, a mixed electrolyte may be used instead of a simple salt, on account of its lower melting point; but the method requires a knowledge of the relation the various metals, present in the mixture, bear to one another in the potential series. From the authors' experiments, it appears that in the case of sodium and potassium, which at low temperatures are electropositive to calcium and strontium, a rearrangement takes place at higher temperatures; and at 800° C. calcium is electropositive to sodium, but still electro-negative to potassium. Thus, on electrolysis of a bath of calcium chloride mixed with sodium chloride at a red heat, sodium free from calcium is obtained; whereas, from a mixture of calcium chloride and potassium chloride, potassium containing considerable quantities of calcium separates.

In a similar way, potassium becomes intermediate between calcium and strontium, since at 800° C. it is electro-negative to the latter.—B. J. S.

Lead; Electrolytic Purification of — in Hydrofluosilicic Acid Solution. H. Senn. Z. Elektrochem, 1905, 11, 229–245.

THE author gives an account of an exhaustive investigation of Bett's method for purification of lead by electrolysis (see Eng. Pat. 7661 of 1902; this J. 1902, 980), using an electrolyte of lead hydrofluosilicate containing gelatin. To avoid the formation of crystals on the cathode, and to obtain a uniform precipitate, the electrolyte should contain 4–8 per cent. of lead, 11 per cent. of hydrofluosilicic acid, and 0.1 grm. of gelatin per litre; the current density being 0.5–1 ampère per sq. dm. For cadmium, the same solution can be used, but it should contain 2.5 per cent. of the metal, and 0.3 grm. of gelatin per litre.

Lead may also be obtained from its alloys with other metals, e.g., copper, bismuth, antimony and platinum, by electrolysis in a similar manner. The alloy is used as the anode, and under suitable conditions of current density, which the author describes, pure lead is deposited on the cathode. During the process of electrolysis the solution is partially decomposed, and a mixture of silica and lead fluoride separate as a mud at the anode. Excessive current density results in the deposition of impurities with the lead, and also causes a loss by increasing the amount of lead separating in the anode mud.—B. J. S.

Slime [Copper and Lead]; Electrolytic Treatment of Electrolytic —. A. G. Betts. Electrochem. and Met. Ind., 1905, 3, 141–145.

THE problem of treating the slime from the refining of copper and lead has been investigated by the author

who proposes the following electrolytic treatment. The slime consists chiefly of finely-divided copper, antimony, arsenic, lead, bismuth and gold, with times iron, sulphur, selenium and tellurium. In refining, arsenic, antimony and bismuth occur slime in the form of oxides. A solution of ferric sulphate of about 4 per cent. strength, is used as a leaching and the copper, which dissolves, is subsequently removed by electrolysis, the ferrous sulphate being simultaneously oxidised back again to the ferric salt. Antimony and the metal obtained by electrolysis of the anode are extracted from the residue with hydrofluoric acid, and the metal obtained by electrolysis of the anode is the trifluoride between lead electrodes, using 10–20 sq. ft. of cathode surface, at 2.6–2.8 volts, the anodes being surrounded with cotton cloth, efficiency attains 92 to 95 per cent. The residue mixed with soda ash and lead, and smelted in a bullion. The electrolytic parting of the bullion effected in a solution of the silver salt of methyl-sulphuric acid, a trace of gum arabic or gelatin being added, the silver deposit to retain a solid form without projecting. The copper and bismuth of the anodes are accumulated in a solution which, from time to time, is worked up precipitating the remaining silver with copper and copper and bismuth with lead. The precipitate of copper and bismuth can be treated with ferric sulphate, bismuth oxide melted to metal. A special form is suitable for depositing the copper and regenerating ferrous sulphate is described.—R. S. H.

ENGLISH PATENT.

Etching of Metal Plates; Process for the —, by Electrolysis. O. C. Strecker, Darmstadt, Strecker, Mayence, Germany. Eng. Pat. 21,374, 1904.

THIS invention relates to a process for the deep etching of zinc by electrolysis, for the purposes of printing pressions from the zinc plates. The zinc is first prepared in the usual or in a special manner, and then arranged as an anode in a bath of zinc acetate, formate or other salt. By using a current strength of at least 2 ampères per sq. dm. of "one-side metallic surface" at the anode and cathode, impure zinc may be used, impurities separating as a slightly adherent soft scale on the anode, whilst the zinc is deposited at the cathode in a firmly adherent form, thus keeping the bath clean and constant. The zinc plate, or other metal with zinc, may be in the form of a cylinder, the surface of which is rotated during the process. With zinc plates, the latter are first treated in an electrolyte bath under the above conditions, so as to remove a surface layer of the metal and, after washing, they are treated for printing purposes and again exposed as anode in the above manner.—B. N.

UNITED STATES PATENTS.

Electroplating Apparatus. L. Potthoff, Flushing, N. Y. U.S. Pat. 786,776, April 4, 1905.

THE material to be treated is conveyed through a means of a travelling belt, the latter being provided with pins which move the material through the electrolyte. The material is supported in a suitable manner, and is in contact with a relatively fixed conductor, an arrangement being provided to automatically change the point of contact of the work with the moving and stationary means and the cathode conductor. The anode consists of bars or rods of the metal to be deposited, the bars being surrounded with porous wrapping, the thickness of which depends on the voltage used. The bars are carried by the material, and make contact with a relative conductor as they move along. The electrolyte is circulated in a direction longitudinally with the material, the latter may be tubular in form, and is fed into the solution in an inclined manner so as to expel the electrolyte.—B. N.

Deposition-Tank [Electrolytic]. I. E. Lewis and J. Corey, London. U.S. Pat. 786,978, April 11, 1905.

THIS invention relates to an electrodepositing apparatus.

particularly applicable for printers' electrotyping, consists of a circular electrolytic vessel with an inner negative electrode carrier in a position coincident with the top annular edge of the vessel. Teeth upon the inner carrier engage with gear for rotating the carrier. The carrier has an annular groove on the under face, and the teeth, respectively disposed in a horizontal and vertical plane, are mounted upon the edge of the vessel and rim of the annular groove for preventing lateral displacement of the carrier. The carrier is provided with a wedge-shaped flange, and hooks, with their extremities inclined to the inclined face of the flange, carry the type or moulds.—B. N.

FRENCH PATENTS.

Alloys; Treatment of —, by Electrolysis. A. Eybert. Fr. Pat. 348,294, Feb. 4, 1904.

The process is applicable to minerals in which the metal is present in the native state or in the condition of oxide. The mineral is powdered and made into a paste with the electrolyte, the nature of the latter depending on the metal to be treated. The paste is placed in boxes with insulated walls, which are so disposed in a containing vessel that they are parallel to each other, and so as to form anode and cathode compartments in which the electrodes are placed parallel to the boxes. With zinc, zinc sulphate is used as the electrolyte, and zinc oxide is formed in the anode compartments and zincate in the cathode compartments. The electrodes are separately purified and then mixed, thus forming the oxide or hydroxide of the metal, and regenerating the sodium sulphate. The former is afterwards washed in order to obtain the pure oxide of the metal.—B. N.

Aluminum; Plating Silver, Gold or other Metals on —. H. H. Hénique, Marret and Bonnin and E. Naviaux. Fr. Pat. 348,399, Feb. 8, 1904.

The invention relates to a process of plating silver, gold, or other metals on aluminum by the aid of a thick paste, which, in the case of silver, consists of 10 parts of tartar, 10 parts of silver nitrate or other salt of silver, and 150 parts of sodium chloride mixed with a small quantity of water. The paste is spread on the aluminum which is then vigorously rubbed with a cloth; the metal is afterwards heated to 250° or 300° C. in a furnace and finally passed between the cylinders of a rolling mill.—B. N.

Ores; Apparatus for the Magnetic Separation of —. G. Gröndal. Fr. Pat. 348,535, Nov. 28, 1904.

A VERTICAL cylindrical electro-magnet is constructed with the actuating coil enclosed by iron pieces, the lower (polar) parts of which converge in the form of a pair of concentric rings. The central, hollow part of the magnet is occupied by a rod carrying at its lower extremity a disc, which is caused to rotate rapidly immediately below the magnet poles. Below the disc is a funnel having within it a conical fixture to upwardly disperse a flow of the finely-divided ore suspended in water, which is injected through a tuyère. A second funnel encloses the former, which second funnel is within a third funnel, the three funnels having separate outlets, each independent of the other. The working of the apparatus is such, that the outlet to one funnel receives the waste ore, whilst the ore retaining more or less of the magnetic particles, is received by the outlets to the other funnels. The metallic particles which collect on the revolving disc are whirled off as they collect, and are caught by a collecting frame. Provision is made for receiving the concentrates.—E. S.

XII.—FATTY OILS, FATS, WAXES, AND SOAP.

Cod-Liver Oil Standards. E. J. Parry. Chem. and Drugg., 1905, 66, 491—492.

THE author discusses the standards for cod-liver oil intended for medicinal purposes, and states that some of Mann's figures, especially those relating to the proportion of unsaponifiable matter, cannot be accepted as correct (see this J., 1903, 1356; also Chem. and Drugg., 1904, 65, 883). The following limits are suggested:—Sp. gr., 0.924—0.931; free acid, not more than 1.0 per cent.; saponification value, "19.9—19.34 per cent."; unsaponifiable matter, not more than 1.5 per cent.; iodine value (Hübl), 155—170; Reichert value, not above 0.7. In the following table the maximum and minimum values obtained in the examination of (1):31 "high-class pale oils," and (2):8 "oils of doubtful purity" are shown:—

gr. at 1° F.	Iodine value.	Saponification value.	Unsaponifiable matter.	Free fatty acids.	Reichert value.	Refractive index.	Fatty Acids.		
							M.pt.	Iodine value.	Mean molecular weight.

Stearin; Notes on —. E. Donath. Chem. Ztg., Fett-u. Harz-Ind., 1905, 12, 42—44; 73—75.

Waxes of various origin are sold under the name "stearin pitch." In the candle industry the crude fatty matter when distilled with superheated steam leave 2 to 7 per cent. of stearin tar or stearin goudron, and this when distilled with similar residues and again distilled at 300° C. leaves a final black viscid residue amounting to 2 to 3 per cent. on the original fatty acids. This stearin pitch is used in the manufacture of lubricating greases, of varnishes, of insulating materials, in the preparation of roofing boards, of waterproof paper (Ger. Pat., 122,893 of 1901), &c. The commercial products sold under the same name are obtained from the distillation of fatty acids separated from washings. They are brownish to black pitchy substances, differing materially in characteristics from the stearin pitch. When examined by the method described by the author and Margosches (this J., 1904, 541)

they will be found to occupy a position midway between true stearin pitch and wool pitch, and the author therefore proposes to describe them as "stearin wool pitch." His observations supplement those of Holde and Marcusson (this J., 1900, 1904). The mineral matter in fat pitches invariably contains copper and iron, whilst stearin wool pitch yields a much larger proportion of ash, containing, in addition to iron, considerable quantities of calcium sulphate.—C. Lakes; *Manufacture of Colouring Matter* ——. J. Y. Johnson, London. From Badische Anilin und Soda
Fabrik, Ludwigshafen-on-Rhine, Germany. Eng. Pat.
10,895, May 11, 1904.

LAKES very fast to water may be made from acid dye-
stuffs by substituting for a portion of the basic aluminium
salt, as defined in Fr. Pat. 342,903 of 1904 (this J.,
1904, 989), zinc oxide or hydroxide, magnesium oxide or
calcium hydroxide, providing that the amount of acid
radical present is between one-sixth and one-twenty-
fourth that necessary to form a normal salt with the bases
present. For example a reddish-yellow lake is prepared
by adding 12 parts of aluminium chloride to a solution in
water of five parts of Naphthol Yellow S, with which has
been incorporated 20 parts of zinc oxide. (Compare Eng.
Pat. 9861 of 1904; this J., 1905, 448).—T. F. B.

*Varnishes and Paints for Waterproofing, Disinfecting, and
like Purposes, also for Indurating Building Materials*;
Manufacture of ——. J. Hargreaves, Widnes. Eng.
Pat. 11,398, May 18, 1904.

VARNISHES suitable for waterproofing and indurating
brickwork, mortar, &c., are prepared by dissolving saponi-
fiable rosin (which forms an insoluble rosinate with the
lime) in one or more of the products of distillation of coal
tar, with the addition of a mineral oil, if desired, to
increase the rapidity of drying, and also with a small
quantity of mineral wax. Antiseptic varnishes are
obtained by using naphthalene, or carbolic or cresylic
acid in the manufacture. One part of rosin may be dis-
solved in two parts of anthracene oil containing about 10 per
cent. of its weight of naphtha, petroleum spirit, &c.;

about 1 per cent. of paraffin wax may be added to pre-
pare the coat of varnish from cracking; 1½ lb. of naphthol
and 1 lb. of carbolic acid may also be added to each
of the varnish. The varnish may also be mixed with
saponifiable oil. Paints are obtained by adding
pigments to the above varnishes.—T. F. B.

UNITED STATES PATENT.

Paint. L. A. Dreyfus, Assignor to Muralo Co.,
Brighton, N.Y. U.S. Pat. 786,348, April 4, 1905.

THE invention relates to a cold-water paint com-
posed of a basic material, a binding or adhesive material, a
volatile, non-saponifiable, non-oxidising olea-
ceous material, such as a non-volatile petroleum product,
is not a solvent of the adhesive material, a volatile
of the petroleum product, and colouring matter.

Claim is also made for a dry paint composition con-
sisting of a powdered mineral base, vasoline, a comminuted
animal adhesive and lime.—A. S.

FRENCH PATENTS.

Paint; *Paraffin [Wax]* ——. M. F. L. Colignon, F.
348,277, Nov. 26, 1904.

A SOLUTION of paraffin wax in mineral oil is used in-
stead of the ordinary drying oils for the manufacture of
Such paints have the advantage of being very sta-
ble, not being resinsified like those prepared in the ordi-
nary manner. Their covering power is also stated to be
superior to ordinary oil paints. (Compare Eng.
Pat. 22,732 of 1904; this J., 1905, 448).—T. F. B.

Lakes [from Azo Dyestuffs]; *Production of* ——. F.
fabr. vorm. F. Bayer und Co. Fr. Pat. 348,426, Feb. 6,
1904. Under Internat. Conv., March 23, 1904.

LAKES of various colours are produced by precipi-
tating on a substratum the dyestuffs obtained by com-
bining diazonium, diazo-azonium, or tetrazonium com-
pounds with acetyl derivatives of *peri*-aminonaphtholsul-
phonic acids. For example, the lake obtained from diani-
line-*o*-sulphonic acid and 1.8-benzoylamino-na-
phthol-4.6-disulphonic acid is yellowish red; that from *p*-
aminiline and the same aminonaphthol derivative, is
red; the lake derived from aminoazobenzene-disul-
phonic acid and 1.8-benzoylamino-naphthol-3.6-disulphonic
acid is bluish-violet, whilst that from dianisidine and 2 n-
1-acetamino-8-naphthol-3.6-disulphonic acid is blue
—T. F. B.

Caoutchouc from a New Species of Euphorbia. H. Ju-
Comptes rend., 1905, 140, 1047—1049.

THE only caoutchouc-yielding species of *Euphorbia*
hitherto known was *E. Intisy*, which grows in the
scrub in the South of Madagascar; the new species
described has received the name of *E. elastica*; it is a
native of Madagascar, being found in the north.
This tree is somewhat scarce, and grows in colonies
frequenting very dry, calcareous soils. The yield of rub-
ber is large; from a tree 12 metres in height 342 grms.
caoutchouc were obtained by transverse incisions with
felling. The caoutchouc is of good quality when pre-
pared; in the crude state it contains about 89 per
cent. of real caoutchouc, 9.5 per cent. of resins and 1.03
per cent. of ash. The coagulation of the latex takes place
easily by simple boiling; alcohol and sulphuric acid
less rapidly, but a decoction of certain roots has

good results as a coagulant. One litre of latex yields 320 grms. of caoutchouc. This is the best rubbering tree in Madagascar, yielding a larger quantity of greater richness than any other plant in the —J. F. B.

UNITED STATES PATENT.

Caoutchouc Substitute; Manufacture of a —. H. Spatz, ineburg, Germany. U.S. Pat. 786,527, April 4, 1905.

Caoutchouc Substitute for caoutchouc is prepared by dissolving "colophonium" in castor oil, heating the solution sulphur to a high temperature, passing ozone through it, and treating the product with sulphur chloride in presence of a solvent and of calcium carbonate. —A. S.

XV.—TANNING, LEATHER, GLUE, SIZE.

GERMAN PATENT.

Leather; Method for the Preparation of an —. H. Hey. Ger. Pat. 155,741, May 6, 1903.

Leather is treated with agar-agar with ozone, an adhesive is obtained which is readily soluble in hot water and furnishes a non-cracking coating after drying. The dried coating is insoluble in water, and the product can be used as an addition to leather, and in the preparation of leather papers. —A. S.

Starch; Reversion of "Artificial" —. E. Roux. Comptes rend., 1905, 140, 943-946.

The author has studied the relative rapidity with which starches of his "artificial" starches (see this J., 1905, prepared from amylocellulose, revert on standing at different temperatures. Three types of "artificial" starches of different degrees of conversion, completely at 150°, 120° and 100° C. respectively, were compared with ordinary potato starch. The solutions were prepared at a concentration of 3.3 per cent. by heating for 10 minutes at 100° C., and for 4 minutes at 150° C. The reversion was more rapid the less soluble the type of starch employed; in the case of the most soluble at 150° C., 43 per cent. had reverted after 24 hours, whereas in that soluble at 100° C., only 1.8 per cent. had reverted. All the "artificial" starches reverted more rapidly than ordinary starch. The presence of acids in certain proportions accelerates the reversion of solutions of "artificial" starch; in the case of a solution of the most soluble type, maximum reversions after 5 days at 0° C., were obtained in the presence of 1 per cent. of sulphuric acid, and of 0.02 per cent. of potassium. The solutions of these "artificial" starches do not revert when maintained at 100° C., but at 150° C. a slight precipitation of unsaccharifiable matter takes place. The reverted product can only be obtained at the same temperature as that at which the original starch was soluble, and possesses the same properties as the latter; the reversion is, therefore, regarded as a return to the initial state. —J. Sugar-Cane; Process of Macerating —. M. Loner, Honolulu. U.S. Pat. 787,402, April 14, 1905.

The sugar cane is passed through a series of several crushing mills in succession, and is macerated after each crushing with heated juice derived from the next crushing mill in the series. Previous to the last crushing the cane is macerated with water only. —J. F. B.

Sugar-Juice; Apparatus for Extracting — [from Bagasse]. J. Rigney, New York. U.S. Pat. 786,154, March 28, 1905.

The apparatus consists of a vertical stand-pipe communicating at the bottom with a short horizontal cylinder. The bagasse is fed into the latter through a hopper, and is forced by a piston to the bottom of the vertical pipe. The latter is provided internally with a vertical shaft carrying pitched blades, which elevate the bagasse, as a loosened mass, through the vertical pipe. The top of the stand-pipe is constricted and fitted with squeeze blades, which discharge the bagasse in a compressed state through an annular opening. A stream of water is introduced at the top of the stand-pipe and flows downwards, extracting the sugar from the ascending material and being drawn off at the bottom through a screened opening, which is maintained clear by the action of a scraper blade attached to the shaft. —J. F. B.

Masseculite; Process of Preparing —. H. Roy, Paris. U.S. Pat. 786,604, April 4, 1905.

SEE Fr. Pat. 337,227 of 1903; this J., 1904, 616. —T. F. B.

FRENCH PATENTS.

Juice from Beetroots and Saccharine Plants; Extraction of —. C. Steffen. Fr. Pat. 348,494, Nov. 11, 1904.

Fresh beetroot pulp is mixed with heated crude juice and passed through the filter-presses; the pressed residues are again pulped with a hot juice of a lower degree of purity than the first juice, prepared by diluting molasses or drainage syrups with saccharine washing liquors. The mixture is again pressed and the resulting juice is utilised for heating a further quantity of fresh pulp. —J. F. B.

Sugar Manufacture and Refining; Heating Apparatus for Boiling Pans for —. Soc. anon. des Constructions Mecan. de St. Quentin. Fr. Pat. 348,508, Nov. 18, 1904.

The usual steam coils of the vacuum pans are replaced by a series of steam drums disposed independently of each other at different heights. These drums have the form of truncated cones or pyramids, and are pierced by a number of tubes through which the juice circulates, thereby increasing their heating surfaces. The steam-drums are so constructed that no part of their surface is in a horizontal position, so that solid sugar cannot accumulate on them. An ordinary steam coil for graining purposes is provided at the bottom of the pan. —J. F. B.

GERMAN PATENT.

Sugar, Lamp; Process for the Preparation of — [from Air-dry Crystal Sugar for Treatment with Steam]. A. Lewenberg. Ger. Pat. 154,987, March 18, 1902.

In the usual process for the preparation of lamp sugar from air-dry crystal sugar, the steam comes directly in contact with the cold sugar. The patentee claims that

if the crystal sugar be warmed with hot air before allowing it to come in contact with the steam, then by varying the temperature and pressure of the steam, the amount of the latter condensed and thereby the quantity of syrup produced can be exactly regulated.—A. S.

XVII.—BREWING, WINES, SPIRITS, Etc.

Barley: Causes of Germination of — W. Windisch and K. Schönwald. *Woch. f. Bran.* 1905, 22, 200—201.

The authors criticise adversely the theory propounded by Nilson (this J., 1904, 379) that the germination of barley is fundamentally dependent upon the activity of the bacteria on the surface of the corns. Having pointed out in a previous paper that Nilson's experiments were carried out without proper control, the authors show that barley can be completely sterilised, without destroying its vitality, by treatment with a solution of mercuric chloride in absolute alcohol. One gram of mercuric chloride was dissolved in a litre of alcohol and various samples of barley were immersed in this solution for eight days. Control tests, made from time to time, by transferring a few of the corns to sterile wort showed that all the samples were absolutely free from micro-organisms after only 24 hours' immersion. The barley was then washed with sterilised water and steeped in aseptic germinating funnels in sterilised water. After steeping, all the samples germinated in a perfectly satisfactory manner, whilst control tests in sterile wort showed that only a small proportion of the germinated corns had become infected during the process. The germinative energy of the treated samples was slightly lower than that of the original barleys, but the total germinative capacities of the barleys were practically unaffected by the treatment.—J. F. B.

Starch: Influence of the State of Liquefaction on the Conversion of — by Saccharifying Diastases. A. Fernbach and J. Wolff. *Comptes rend.*, 1905, 140, 1067—1069.

THE phenomenon of the saccharification of starch, like that of the coagulation (see this J., 1905, 99), depends largely on the state of liquefaction. The superposition of the liquefying and saccharifying processes, which results when malt diastase is employed, can be avoided to a large extent by using an infusion of barley, which is almost devoid of liquefying diastase. An extract of barley was allowed to act for five hours at different temperatures upon two portions of a potato starch paste, one of which had been prepared at 100 °C., whilst the other was liquefied under pressure at a temperature of 140—145 °C. for two hours. The converted products were then analysed by precipitating the unsaccharified starch by excess of baryta water, and determining the dextrins and sugars in the filtrates. In the case of the liquefied starch, the quantity of conversion products was greater than in that of the ordinary paste. The liquefaction of the starch paste by a limited quantity of malt extract at 70 °C. had the same effect as liquefaction by heating under pressure. A mixture of barley extract with a minute quantity of malt extract, insufficient for the complete saccharification of the starch, saccharifies far more energetically than either of the constituents separately.

The pastes of the cereal starches are saccharified by barley diastase far more easily and completely than potato starch paste; it is concluded therefore that the natural state of liquefaction of the cereal starches approaches that of potato starch liquefied artificially.—J. F. B.

Yeast; Respiration and Fermentation of Different Species of Dead — Warschowsky. *Centrabl. Bakt.*; through *Brewers' J.*, 1905, 41, 270.

THE author has studied the relation between the production of zymase and the species and environment of the yeast producing it, the quantity of gas furnished by the zymase being taken as a measure of the enzymic process. The yeasts were grown in various nutrient media, including Laurent's solution of triple strength, with 4.55 per cent. of

mannitol in one case, and 2.3 per cent. of glycerol in another, whilst in a third, the normal solution was used, the potato being replaced by ammonium phosphate, with the addition of 4.5 per cent. of dextrose. The resulting yeast cultures were killed by means of acetone, and the products tested for the presence of zymase. The results show that when yeasts capable of setting up alcoholic fermentation were cultivated in fermentable media, zymase was produced, but no zymase was formed when the yeasts grown in media containing no fermentable carbohydrate. *S. Pombe*, however, formed no zymase when grown in a fermentable medium in which the source of nitrogen was ammonium phosphate.—J. F. B.

Vinegar: Chemistry of Home-made Cider — J. I. van Slyke. *New York Agric. Exp. Station, Bulletin No. 258*, 439—494.

ANALYSES of apple juices representing 83 varieties of American-grown apples are given, and the changes in the composition of the juice undergoes during alcoholic and acetic fermentations have been studied under various conditions. The chief factor in the production of vinegar of standard strength is the percentage of sugar in the juice; unripe and over-ripe apples are deficient in sugar. At the temperature of an ordinary cellar, most of the sugar is converted into alcohol in five to six months; addition of yeast hastens the fermentation. For a successful fermentation, the necessary conditions are the presence of proper ferment, an abundant supply of air and a high temperature. At cellar temperatures acetic fermentation requires about 18 months. Decantation of the liquid after alcoholic fermentation favours acetic fermentation. A vinegar of standard quality should contain at least 4.5 per cent. of acetic acid. With careless storage at a high temperature, the acetic acid is liable to destruction by other organisms which only act in the presence of air; this can be prevented by decanting the vinegar into clean barrels, filled to the top and tightly corked. These organisms also cause a decrease in the solid extract. The malic acid of the juice disappears almost entirely during acetic fermentation, but the decrease is less marked when the apple juice has been sterilised. The solid extract very frequently decreases to a point below 2 per cent. during fermentation, but under normal conditions there is a subsequent increase due to evaporation. A normal vinegar containing more than 4.5 per cent. of acetic acid may contain less than 2 per cent. of solids.

In making cider vinegar only clean ripe apples, yielding a juice containing at least 8.5 per cent. of sugar, should be used; the grinding and pressing should be effected under conditions of great cleanliness, and a second pressing of watered pomace is to be avoided. The barrels must be sealed and then filled about three-quarters full of the bung holes being loosely plugged with cotton. The temperature of the cellar should be 65°—70° F. If a fairly rapid fermentation is desired, a certain proportion of pressed yeast may be added. When the alcoholic fermentation is complete, the clear liquid should be decanted, the barrel should be washed out, and the liquid returned to it, with the addition of two or four quarts of second vinegar containing some "mother." The temperature should be maintained between 65° and 75° F.; the bung should be left out until the vinegar contains the standard proportion of acid. Finally the vinegar should be decanted into clean barrels and stored with exclusion of air.—J. F. B.

Starches; Reversion of "Artificial" — E. J. XVI., page 507.

ENGLISH PATENT.

"Beverages, Fermented" — [Ginger Beer]. W. and T. Dempster, both of Perth. *Eng. Pat.* 47, March 5, 1904.

To obtain a beverage containing less than 2 per cent. of proof spirit, and of which the alcoholic strength will increase on keeping, the ingredients are treated in the usual way, and fermented until the required quantity of alcohol is produced. After straining, carbon dioxide

l in and the liquid filtered under pressure into The corked or stoppered bottles are then pas- in the usual way.—W. P. S.

UNITED STATES PATENT.

Process of Manufacturing Non-Alcoholic ——. V. pp, Leipsic, Germany. U.S. Pat. 786,771, April 4, 1905. g. Pat. 11,223 of 1903; this J., 1903, 921.—T. F. B.

Manufacture of Dried ——. H. Hahn. Fr. Pat. 348,573, Dec. 5, 1904.

ast, after washing and pressing, is placed in a closed drying vessels, each composed of an outer and an inner container, the latter being provided with wire sieve bottom, through which air is forced the mass of yeast. The air is pumped through a wool filter; it then passes through a charcoal and is compressed in a reservoir. From the r the sterilised air passes through a worm immersed a vessel of hot water, and through another worm ded by cold water, and from either of these it to the drying vessels. The yeast is first partially y a current of cold air at a temperature of 14° C.; deation proceeds, the temperature of the air is dly increased until the final drying is effected at a ture of 35° C. The dried yeast falls through the to a box below.—J. F. B.

g and Converting; Process of ——. C. H. Caspar and P. Fitzgerald. Fr. Pat. 348,597, Dec. 6, 1904. 3. Pat. 776,999 of 1904; this J., 1905, 39.—T. F. B.

III.—FOODS; SANITATION; WATER PURIFICATION, & DISINFECTANTS.

(A.)—FOODS.

Cheddar; Relations of Casein and Paracasein ases and Acids, and their Application to ——. van Slyke and E. B. Hart. New York Agric. Stat. Bull., 1905 [261], 1—37. (See this J., 1903, 922, 1253.)

free from ash or nearly so, was obtained by pre- g dilute skimmed milk with acids, the excess of together with inorganic matter, being removed by d filtration and trituration with water. The required several days. From this casein free ses, preparations were made in which the proteid nbined with about 2.4 per cent. of calcium oxide, g basic calcium-casein. One such preparation was y triturating the proteid with calcium carbonate ter, and another by dissolving the casein in lime- and making the solution neutral to phenolphthalein addition of acid. By rendering the lime-water u of the proteid neutral to litmus, neutral calcium- was obtained containing about 1.5 per cent. of oxide. These two calcium compounds are not ed by rennet, but neutral calcium-casein after nt with rennet is coagulated at ordinary tempera- y soluble calcium salts. Calcium chloride coagu- ath compounds on warming to 35° to 45° C. The s consider that casein is probably present in cow's neutral calcium-casein.

casein free from bases mentioned above is plastic arm, readily soluble in 5 per cent. sodium chloride n, and in hot 50 per cent. alcohol, and is identical he compounds formerly regarded by the authors ein mono-salts. Similarly, the compounds which reviously called casein di-salts, are really com- s formed by the combination of acids with free

eparation of paracasein free from bases—obtained luting milk with ammonium oxalate, filtering, acting with rennet for 2 hours at 37° C., diluting and pre- ing with hydrochloric acid—was dissolved in lime-

water, and from this solution basic calcium-paracasein, containing 2.40 per cent. of calcium oxide, and neutral calcium-paracasein, with 1.5 per cent. of calcium oxide, were prepared. These compounds so closely resembled those of casein in their properties that it is probable they are chemically alike, paracasein only differing from casein by consisting of a larger molecular aggregation. Free paracasein appears to be identical with the compounds previously called paracasein mono-salts.

The compounds dissolved by a warm 5 per cent. sodium chloride solution and hot 50 per cent. alcohol, from fresh Cheddar cheese which has been previously extracted with water, appear to consist of free paracasein, instead of paracasein mono-lactate as previously stated by the authors.

As regards the chemical changes in calcium-casein when milk becomes sour or is acidified, it is found that the acid first combines with the bases of some of the inorganic salts of the milk, and then with the calcium that is combined with the casein, liberating free casein. When more acid is added, the free casein combines with it. The coagulum obtained by the addition of rennet to milk is calcium-paracasein, either mixed or loosely combined with soluble calcium salts. While lactic acid is being formed in the process of cheese-making, it combines with the calcium of the calcium-paracasein, forming free paracasein and calcium lactate.

It is suggested that, to avoid confusion, the following nomenclature be used:—(1) That the compound existing in cow's milk be called calcium-casein; (2) that only the free proteid be called casein; (3) that the compound containing 2.4 per cent. of calcium be called basic calcium-casein; (4) that a compound formed by precipitation and combination with an acid be called a casein salt of that acid; (5) that the same nomenclature be applied to paracasein bodies, with the following addition—calcium-paracasein should be applied to the uncoagulated form and the term *coagulated* calcium-paracasein to the coagulated modification.—W. P. S.

Cream-Separators; Impts. in ——. P. H. Watts, Dursley, Glos. Eng. Pat. 11,732, May 21, 1904.

A NUMBER of cones are placed in the drum of the separator, the cones being corrugated or ribbed. The corrugations commence at or near the base of the cones, and increase in depth towards the upper part, where they form two different inclines with suitable filling and exit provisions. The cones are separated from each other by projecting pieces, and may be provided with the usual hole. In shape, the corrugations may be straight or curved from the vertical.—W. P. S.

[Milk] Separators; Impt. in Centrifugal ——. E. A. O.

Prolius, Copenhagen. Eng. Pat. 14,960, July 4, 1904. THE milk is fed into the inlet chamber *a*, and rises through a series of inlet tubes *b*, the centres of which are arranged in a circle about the axis of the apparatus. The tubes *b* are provided with slots or holes *c* which open into the nest of conical separating plates and with other openings *e* for the purpose of allowing the layers of air *d*, which form owing to the centrifugal force, and which prevent the tubes *b* from becoming completely filled with liquid, to communicate with the exterior of the tubes *b* and so regulate the pressure. The following advantages are claimed:—

1. Owing to the equalising of the pressure, an even feeding of the milk on to the conical plates is secured.

2. The separated cream particles do not adhere either to the inside or outside of the inlet tubes.

3. The same pressure is always maintained in the air-ducts within the milk-way and the cream-way.—W. H. C.

[Milk] Separators, Impts. in Centrifugal — B. A. O. Prolius, Copenhagen. Eng. Pat. 14,961, July 4, 1904.

GROOVES of approximately V-shaped cross section are formed at the inner edge of the separating plates, and merged into the inclined surfaces so that when the plates are assembled in the bowl of the centrifugal machine, exact centering and proper relative distance between them is assured. Further the grooves are arranged opposite the outlets of the milk-supply tubes, in order that the liquid may flow through the grooves and be spread uniformly over the plates.—W. H. C.

Food and Beverages; Sterilisation of — C. C. L. G. Budde, Copenhagen. Eng. Pat. 13,651, June 16, 1904.

A CONSIDERABLE quantity of hydrogen peroxide is added to the beverage, &c., to be sterilised, which may then be heated to 40° C., in a closed vessel to prevent loss of carbon dioxide. The excess of hydrogen peroxide is afterwards destroyed by the addition of powdered charcoal, or platinum and similar metals in a finely-powdered or colloidal state. These are removed by filtration, or allowed to settle, before the beverage is bottled.—W. P. S.

UNITED STATES PATENT.

Milk Powder containing Cream; Process of Obtaining a — C. H. Campbell, Philadelphia, Pa., Assignor to National Nutrient Co., Jersey City, N.J. U.S. Pat. 786,626, April 4, 1905.

SKIMMED milk is concentrated at a moderately low temperature by forcing a current of air through it, until it is reduced to about one-sixth of its original volume. Cream is now added, and the mixture dried at a temperature below 150° F. The product has a flavour of cream. —W. P. S.

Milk or other Liquids; Process of Sterilising — C. de Jong, Amsterdam. U.S. Pat. 786,819, April 11, 1905.

SEE Eng. Pat. 5446, 1903; this J., 1904, 201.—W. P. S.

Milk; Condensed — S. R. Kennedy, Assignor to the American Dairy Products and Manufacturing Co., Philadelphia, Pa. U.S. Pat. 787,044, April 11, 1905.

A PRODUCT is claimed consisting of milk condensed to a thick syrup and containing the usual constituents of condensed milk, except the sugar and salts, which are present only in a greatly reduced proportion. (See also U.S. Pat. 772,517, 1904; this J., 1904, 1105.)—W. P. S.

FRENCH PATENTS.

Cereals or other Analogous Matters or their Grist; A process for Extracting Liquid or Volatile Oils from, and Drying — W. J. Wells. Fr. Pat. 348,523, Nov. 24, 1904.

SEE Eng. Pat. 23,183 of 1904; this J. 1905, 427.—T. J.

Condensing [Evaporating Albuminous] Liquids; A process for — H. W. Southworth. Fr. Pat. 348,518, Nov. 24, 1904.

SEE Eng. Pat. 24,870 of 1904; this J., 1905, 123.—T. J.

Milk Powder or Food; Manufacture of a — Raveau. Fr. Pat. 348,640, Dec. 8, 1904.

MILK is evaporated by passing it between two porcelain or stone-ware cylinders heated to a temperature of 120° C. The dry powder obtained is mixed with sugar, vanillin, coffee extract, &c.—W. P. S.

GERMAN PATENTS.

Juices, Animal or Vegetable; Obtaining Dry Preparation of —, for Alimentary or Medicinal Purposes. — Meyer. Ger. Pat. 154,732, Dec. 2, 1902.

DRY preparations of animal or vegetable juices or extracts are produced by adding to the juice the necessary quantity of a salt from which the water of crystallisation has been removed.—T. F. B.

Albumin Solutions; Method for the Preparation of — W. Holtschmidt. Ger. Pat. 154,935, Dec. 10, 1902.

ALBUMIN or a substance containing albumin is subjected to the action of an acid capable of forming hydrates, such as sulphuric acid, the acid being employed in a partially hydrated condition. The substance is mixed with a quantity of the acid to form a plastic, dough-like mass, and it is stated that with an acid capable of forming hydrates, such as sulphuric acid, a gradual liquefaction takes place, even in the cold, with formation of albumin, albumoses and peptones.—A. S.

(B).—SANITATION; WATER PURIFICATION

ENGLISH PATENT.

Sewage; Treatment of — [Charcoal Filters]. — Wanklyn and W. J. Cooper, New Malden. Eng. Pat. 8857, April 18, 1904.

LARGE or small masses of wood charcoal are placed in sewage channels to form a series of floating filters. The pieces have drifted into position, more charcoal is placed on them, so that part of the filter is forced to the surface of the sewage, which must flow from the or channel at the top. The charcoal may be packed in bags provided with ropes by means of which they are drawn out of the sewage from time to time for purpose of revivification.—W. P. S.

FRENCH PATENT.

Water; Purification of —, by Continuous Precipitation and Decantation. E. Declercq. Fr. Pat. 348,375, Nov. 30, 1904.

THE water, after being mixed with regulated quantities of precipitating reagents, enters the lower part of a tank having a conical bottom. The water here encounters the sediment of previous precipitations which considerably increases the rapidity of the formation of the fresh precipitate. As the latter collects it is drawn off by means of a vertical covered pipe extending about half the height of the interior of the tank, whilst the clear water overflows at the top of the tank, first passing over the edge of a basin-shaped baffle plate.—W. P. S.

GERMAN PATENT.

Water; Process for the Separation of Iron from — G. Bruhns. Ger. Pat. 154,792, Oct. 18, 1902, Added to Ger. Pat. 145,797, March 16, 1902.

ACCORDING to the main patent, the water was passed

filters composed of an organic or inorganic porous substance impregnated with manganese in a state of fine division. It is now found that manganese peroxide can be replaced by other oxidized oxides of manganese.—A. S.

(C).—DISINFECTANTS.

Composition of Commercial — in Relation to Fungus [Fruit Trees]. L. L. van Slyke and F. A. New York Agric. Expt. Stat., 1904, Bull. No. 427—438.

very variable results obtained on spraying fruit trees. The results of commercial whale-oil soaps are due to the composition of such soaps. In nine examined by the authors, the proportion of water from about 11 to 55 per cent., and that of free alkali 0.1-30 per cent. The authors recommend that the prepared by the user, and the following formula stated:—Caustic soda, 6 lb.; fish oil, 22 lb.; water, 100 lb. A solution of 1 lb. of a soap prepared in this way, 2 gal. of water gave good results when used for spraying pear, plum, currant cherry and peach trees, containing up to 5 per cent. of free alkali had no effect on the foliage of the trees.—A. S.

ENGLISH PATENT.

Processes and Paints for Waterproofing, Disinfecting, and other purposes, also for Endurating Building Materials; Manufacture of — J. Hargreaves. Eng. Pat. 13, May 18, 1904. XIII. A., page 506.

UNITED STATES PATENT.

Compound for Firemen's Use. W. M. Mitchell, Louisville, Ky. U.S. Pat. 786,543, April 4, 1905. The preparation consists of a mixture of menthol, terpineol, and ammonia.—W. P. S.

IX.—PAPER, PASTEBOARD, Etc.

UNITED STATES PATENTS.

Machine for Making Paper and Process for — R. Binns, Windham, Conn. U.S. Pat. 785,704, March 28, 1905.

The paper-making machine of the cylinder type, the "making" cylinder is so arranged as to form a vat of the pulp. The web of paper is thus dried by percolation on the rising surface of the vat below the level of the liquid in the vat; it is then on an endless felt in the usual way.—J. F. B.

Machine. K. E. Rogers, S. Manchester, Conn. U.S. Pat. 786,996, April 11, 1905.

The machine consists of a non-rotating suction-box extending obliquely under the surface of the pulp vat in a vat. A wiper-fabric belt, supported by rollers inside and outside the vat, passes around the suction-box, emerges in a plane parallel to the perforated upper surface of the latter. The pulp is caused to adhere to the belt in a continuous web under the influence of the suction inside the box, and the web is transferred to an endless felt and finished in the usual way.—J. F. B.

Process. C. de Büren, Geneva, Switzerland. U.S. Pat. 786,343, April 4, 1905.

The process of about 70 per cent. of "pure celluloid," or 10 per cent. of a lead salt having a sp. gr. greater than 3, such as lead carbonate, is claimed as a new process for the manufacture of golf balls.—A. S.

FRENCH PATENT.

Artificial; Method of Coating Tissues or Paper with Cellulose. L. Richard and J. Jacquin. Fr. Pat. 483,354, Nov. 29, 1904. V., page 495.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES, AND EXTRACTS.

Lithium Citrate. D. B. Dott. Pharm. J., 1905, 74, 440.

The British Pharmacopœia has previously been shown to be inaccurate in describing lithium citrate as deliquescent, and in regard to the temperature at which the salt loses the whole of its water. The author now points out that the official statement that lithium citrate loses 10 per cent. of moisture at 100° C. is also quite incorrect. Direct experiments showed that the loss of moisture near 100° C. amounted to about 24.7 per cent., corresponding to four molecules of water.—A. S.

Glycerolphosphoric Acids; Relation between Natural and Synthetical — F. B. Power and F. Tutin. Chem. Soc. Trans., 1905, 87, 249—257.

The authors confirm the statement of Carré (see this J., 1904, 35) that when glycerolphosphoric acid, $C_3H_5(OH)_2O_2PO(OH)_2$, is prepared at temperatures above 110° C., it is associated with varying amounts of the di-ester

It is to this fact that the discrepancies of statement respecting the composition and characters of the salts of glycerolphosphoric acid are due (compare this J., 1895, 60; 1898, 66, 179, 266, 368). The authors prepared the calcium, strontium, barium, lithium, manganese, and zinc salts of glycerolphosphoric acid under conditions which excluded the formation of the di-ester. The calcium, strontium and barium salts, after drying in a vacuum, were all nearly anhydrous. The calcium salt, $C_3H_5(OH)_2O_2PO_2Ca$, forms tufts of crystalline leaflets when its cold saturated solution is heated; it is soluble in 22.4 parts of water at 16° C., in 25.2 parts at 25°; and in 108.6 parts at 100° C. Lithium glycerolphosphate when air-dried contains 6.9 per cent., or between one-half and one molecule of water. Zinc glycerolphosphate unlike the other salts mentioned is more easily soluble in hot than in cold water; it readily crystallises in colourless glistening plates when its hot concentrated solution is cooled. On heating at 125° C. it appears to be converted into a basic salt insoluble in water.

The authors also criticise the recently published work of Willstätter and Lüdecke (Ber., 1904, 37, 3573) in which the barium and calcium salts of the natural and synthetical glycerolphosphoric acid were compared, and the conclusion drawn that the differences between them are not those which are usually observed in the case of optically active and racemic compounds. These differences consisted in the amount of metal contained in the respective salts, in the varying amounts of water believed to be retained by them when dried at certain temperatures, and in their relative solubility. It is stated that the conclusions of Willstätter and Lüdecke cannot be accepted, inasmuch as their synthetical glycerolphosphoric acid was prepared under conditions which have been proved to afford some of the di-ester, and the discrepancies they have observed are, to a large extent, due to the contamination of their salts of the synthetical acid with those of the di-ester, rather than to the amount of water retained by them when subjected to heat. (See also this J., 1896, 556; 1897, 553; 1898, 73, 78, 386, 500, 598, 864; 1899, 603; 1900, 80.)—A. S.

Linin. J. S. Hills and W. P. Wynne. Chem. Soc. Trans., 1905, 87, 327—331.

The authors believe the active principle of *Linum catharticum* ("purging flax"), a small indigenous herb, to be a glucoside, which on hydrolysis with dilute acids or with lime yields dextrose and a substance apparently identical with Schröder's linin (Nenes Rep. Pharm., 1861, 10, 11). The best yield of linin is obtained by digesting the dried herb with one-fifth of its weight of slaked lime and ten times its weight of water at 80—90° C., for six hours, concentrating the filtered solution to about one-tenth of its volume, and boiling for five minutes with hydrochloric acid. The greater part of the linin separates in a crystalline form on cooling, and the remainder

can be obtained by extraction with ether. With 500 grms. of the herb, the yield of linn was 0.135 per cent., and with 21.5 kilos., 0.126 per cent. The crude linn was purified by crystallisation from absolute alcohol, solution in ethyl acetate and precipitation with light petroleum. The pure compound forms long glistening needles melting with decomposition at about 205° C.; the melting-point, however, varies with the rate of heating. Linn has the composition $C_{24}H_{24}O_6$, is fairly easily soluble in chloroform and acetic acid, sparingly soluble in methyl and ethyl alcohols, acetone, ether and benzene, and insoluble in light petroleum, water, and hydrochloric acid. It dissolves in a boiling, dilute solution of sodium hydroxide, and is reprecipitated unchanged by addition of hydrochloric or sulphuric acid. It yields oxalic acid on oxidation with nitric acid or potassium permanganate, and it contains four methoxyl groups. It has properties remarkably similar to those of picropodophyllin (this J., 1898, 268). A mixture of equal parts of linn (m. pt., about 205° C.) and picropodophyllin (m. pt., 227° C.) melts at 184° C.—A. S.

Saccharin; Determination of—C. Proctor, XXIII., page 514.

Cod Liver Oil Standards. E. J. Parry. XII., page 505.

ENGLISH PATENTS.

Barbituric Acid; Manufacture of Derivatives of—C. D. Abel, London. From Act.-Ges. f. Anilinfabr., Berlin. Eng. Pat. 11,259, May 16, 1904.

DIALKYLTHIOBARRITURIC acids of the constitution $CS:(NH.CO)_2:CR_2$, are prepared by condensing thiourea with dialkylmalonic esters in presence of metal alcoholates.—T. F. B.

Pyrimidine Derivatives; Manufacture of—H. E. Newton, London. From Farbenfabr. vorm. F. Bayer und Co., Elberfeld, Germany. Eng. Pat. 12,091, May 27, 1904.

IN U.S. Pat. 744,732 of 1903, (see this J., 1904, 35) and Eng. Pat. 21,833 and 22,967 of 1903 (this J., 1904, 76) processes were described for the preparation of pyrimidine derivatives of the general formula—

where X represents O, NH or S, and R and R' alkyl radicals. It is now found that the condensations therein described can be carried out in presence of alkali amides or alkali metals instead of with alkali alcoholates. The condensation of alkyl cyanoacetic esters with guanidine may also be brought about without the use of a condensing agent, the 2,4-di-imino-5-alkyl-6-oxypyrimidine being produced by heating an alcoholic solution of the two components for some hours at about 100° C.—T. F. B.

UNITED STATES PATENT.

Carbon Tetrafluoride Gas; [Electrolytic] Manufacture of—J. A. Lyons and E. C. Broadwell, U.S. Pat. 785,861, March 28, 1905. XI. A., page 503.

FRENCH PATENTS.

Metals, Colloidal; Preparation of Organo-metallic—J. Bonnet. Fr. Pat. 348,330, Feb. 5, 1904.

COLLOIDAL metals are prepared by mixing a solution of a metallic salt (e.g., of copper, iron or manganese) with one of albumin, gelatin, dextrin, &c., in presence of a small quantity of alkali. The solution should be made with distilled water free from oxygen, and in absence of air. Such a solution may be prepared by adding 1 or 2 c.c. of a 1 to 5 per cent. manganese chloride solution to 1 litre of the solution of albumin, &c., and then adding a few c.c. of decinormal sodium hydroxide solution. The solution thus obtained is colourless, and possesses energetic oxidising power. If the preparation be made in air, or if the above solution be kept in air, it turns brown, and gives indications of the presence of manganese dioxide, which, however, is not precipitated.

If the solution is heated to 100° C., it loses its power of oxidation. The colloidal compounds may be obtained in solid form by precipitation with alcohol, or by evaporation *in vacuo*.—T. F. B.

Pinene Hydrochloride; Process for Purifying Solid—J. Schmeitner and L. Morane. Fr. Pat. 348,618, 15, 1904.

CRUDE pinene hydrochloride, obtained by passing hydrochloric acid gas through turpentine oil, is washed with dilute alkali and then with water. It is then subjected to a treatment with some oxidising agent, e.g., permanganate two to three parts of permanganate in aqueous solution being used for every 100 parts of the hydrochloride. Oxidation of the impurities may be carried out in cold, but it proceeds more rapidly at higher temperature. The manganese dioxide formed (which imparts a brown colour to the product) is removed by treatment with sulphur dioxide, and the product is then washed and dried. Pinene hydrochloride purified in this way is stated to be quite stable, not becoming acid on keeping. (See Fr. Pat. 328,009 and addition thereto; this J., 1903, and 1904, 336.)—T. F. B.

Citral Series; Process for the Transformation of Perfumes of Compounds of the—E. Knoevenagel. Fr. Pat. 348,484, Nov. 8, 1904. Under Internat. C. Nov. 10, 1903.

Juices, Animal or Vegetable, for Alimentary or Medical Purposes; Obtaining Dry Preparations of—Meyer. Ger. Pat. 154,732, Dec. 2, 1902. XVII. A., page 510.

Lecithin; Process for Obtaining Preparations of Containing Iodine. J. D. Riedel. Ger. Pat. 156,290, April 28, 1903.

AN IODO derivative of lecithin is produced by the action of iodine monochloride, or a substance having a similar action, on lecithin. A solution of 5 kilos. of lecithin in three litres of alcohol is shaken with 10 litres of hydrogen iodide solution at a temperature of 40°–50° C.; the solution is cooled, filtered, and evaporated *in vacuo*. The product contains up to 20 per cent. of iodine.—T. F. B.

Bromolecithin; Process of Preparing—Act. f. Anilinfabr. Ger. Pat. 156,110, July 28, 1903.

BROMOLECITHIN is prepared by the action of bromine on lecithin, which is capable of taking up 50 per cent. weight of halogen.—T. F. B.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

ENGLISH PATENTS.

Emulsions, Photographic Sensitive; Base or Support for—J. Findlay, Ilford. Eng. Pat. 5948, March 11, 1904.

A NON-INFLAMMABLE base or support for use in preparing "flat" or "roll" films for photographic purposes may be prepared as follows:—7½ kilos. of glacial acetic acid containing 90 grms. of chloral hydrate are warmed with 1 kilo. of mono- or di-nitro-cellulose and 2.5 kilos. of clear, hard gelatin or glue until solution is complete. Eight litres of a 2 per cent. solution of equal parts of gum dammar and gum storax in 70 per cent. alcohol are then incorporated with the solution, and the mixture poured into suitable moulds, or on to slabs. When the sheets or films are dry, they are rendered non-inflammable by immersion in an alkaline solution of shellac, prepared, for example, by dissolving one part of borax and one part of gum shellac in 10 parts of water.—T. F. B.

XXIII.—ANALYTICAL CHEMISTRY.

INORGANIC QUALITATIVE.

fluosilicic Acid; Behaviour of — to certain reagents. A. Gawalowski. Z. anal. Chem., 1905, 44, 1—194.

Aqueous solution of hydrofluosilicic acid behaves with reagents as follows:—Dilute sulphuric acid—white precipitate, insoluble in nitric acid; hydrochloric acid—precipitate, somewhat soluble in hot water and acid; potassium chromate—yellow precipitate, soluble in nitric acid; potassium bichromate—orange precipitate; potassium chlorobichromate—orange precipitate.—C. E. F.

Line [in Portland Cement]; Alkaline Reaction — in Absolute Alcohol. E. Drexel, Tonnard, Z. anal. Chem., 1905, 44, 29, 311. (See also this J., 1905, 210.)

In the author's opinion no colour reaction between Portland cement and a solution of phenolphthalein in absolute alcohol can be due to the presence of free lime, since if the lime remain undissolved no hydroxyl ions are formed, and even if the lime deprived the alcohol of the element of water, it would be necessary for the resulting calcium and hydroxyl to be present in a state of dissociation, which is not the case. Furthermore, any such power of decomposing alcohol would presumably be shared by the calcium oxide molecule combined with silica, so that the colour reaction would not necessarily be an indication of the presence of free lime.—C. S.

INORGANIC QUANTITATIVE.

Acidimetry; Sodium Carbonate and Sodium Oxalate as Standard Substances in —. S. P. L. Sørensen and A. C. Andersen. Z. anal. Chem., 1905, 44, 156—184.

The value of sodium oxalate as a standard in acidimetry has been shown by Sørensen (this J., 1900, 1041; 1903, 1015). Lunge (Z. angew. Chem., 1904, 17, 225—265) has commented favourably on the use of sodium oxalate, but states that it gives results differing by 0.1 per cent. from the results obtained by the use of sodium carbonate. The authors find that the results obtained by the two methods are almost identical, the differences never reaching 0.1 per cent. Any small difference is due to the impossibility of preparing sodium carbonate quite pure (from bicarbonate). The method for using sodium oxalate is as follows:—A specimen of pure sodium oxalate, which has been heated to 240° C. and then exposed to ordinary air, is weighed into a platinum crucible and heated by means of a spirit lamp—a gas flame should not be used. The residue, on cooling, is treated with N. 10 hydrochloric acid in slight excess, the solution is boiled, some phenolphthalein added, when it is again boiled, whilst a current of air, freed from carbon dioxide, is being passed through. When cold, the liquid is titrated with N. 10 sodium hydroxide solution, using phenolphthalein as indicator. The numbers obtained by standardising hydrochloric acid with sodium oxalate differ by 0.05 per cent. from the value got by a gravimetric determination of the chlorine in the acid, or by weighing the hydrochloric acid in the solution. According to Lunge methyl orange has the advantage of not being acted on by carbonic acid; the authors find that this is not the case, and recommend that in exact work the same amount of carbonic acid should be present in any solution which is being analysed as in the solution when the standardisation was carried out.

—C. E. F.

Limestones; New Method for the Determination of Magnesium Carbonate in —. W. F. Koppeschaar. Z. anal. Chem., 1905, 44, 184—187.

The bulk of the calcium is precipitated as sulphate. Fifty grms. of the limestone are treated with 500 c.c. of 2N. hydrochloric acid until dissolved; 50 c.c. of concentrated sulphuric acid are then added, and the calcium sulphate filtered off through a Büchner funnel. The filtrate, after being made alkaline with ammonia, is treated with 5 grms. of ammonium oxalate and filtered. The magnesium is precipitated from the filtrate by adding 4 grms. of sodium phosphate.—C. E. F.

Hydrofluoric Acid [Use of — in the Determination of Iron and Aluminium]. E. Deussen. VII., page 496.

ORGANIC—QUANTITATIVE.

Milk referred to the Government Laboratory in connection with the Sale of Food and Drugs Acts; Analysis of Samples of —. T. E. Thorpe. Chem. Soc. Trans., 1905, 87, 206—225.

SAMPLES of milk referred by magistrates to the Government Laboratory for examination, are invariably sour when received, and it has been of importance therefore

to determine the influence of the changes which occur during the process of souring on the amounts of fat and non-fatty solids in the milk. With regard to the fat, it was found that bacteria which produce steatolytic enzymes do not develop to any considerable extent in sour milk, and that any alteration in the amount of fat caused by fermentation is so small as to be negligible. The somewhat complicated changes which take place in the non-fatty solids of milk during the souring process were examined in detail. The partial conversion of the lactose into lactic acid does not involve any change in weight, but comparative experiments with fresh milk, and milk which had been kept for varying periods of time, showed that concurrently with the formation of lactic acid, there are produced substances which are either gaseous at ordinary temperatures, or are volatilised during the operation of determining the non-fatty solids. Among the compounds detected were *n*-butyric acid, acetic acid and ethyl alcohol. Butyric acid is formed from lactic acid according to the equation:

The production of each molecule of butyric acid thus involves the loss of two molecules each of carbon dioxide and hydrogen. Acetic acid may be produced by the oxidation of lactic acid or of ethyl alcohol. In the first place there is a loss of one molecule each of carbon dioxide and water, and in the second case, of one molecule of water only for each molecule of acetic acid formed.

The ethyl alcohol may be produced in various ways, but in any case the formation of each molecule of alcohol is associated with the production of one molecule of carbon dioxide, so that the total loss of weight in the lactose due to the production of alcohol and carbon dioxide is $\frac{3}{2}$ times the weight of alcohol produced.

With regard to the proteid substances contained in milk, the losses caused by the changes which take place during the process of souring are almost negligible. The only loss which it is necessary to take into consideration is that due to the formation of a small quantity of ammonia. In considering the influence of these changes, it is pointed out that most of the samples dealt with in practice are only fermented to a relatively small extent; they are between three and six weeks old, have been preserved in sealed bottles containing only a limited quantity of air, and the total diminution in weight of the non-fatty solids, due to the formation of volatile products, is usually only a few tenths of 1 per cent. (from 0.2 to 0.5 per cent.). Further, in determinations of the non-fatty solids in the same sample of fresh milk by different persons, the results may frequently differ by 0.1–0.2 per cent. The following scheme of analysis is adopted in the Government Laboratory. The sample of milk is thoroughly mixed with a wire whisk, and about 10 grms. are weighed out into a flat-bottomed platinum capsule, which has been tared along with a short glass rod having a flattened end. The milk is neutralised with N/10 solution of strontia, using phenolphthalein as indicator, and is evaporated over the water-bath until the residue, which towards the end should be dried at a very gentle heat and with constant stirring, attains the consistency of dry cheese. The residue is then triturated with 20 c.c. of dehydrated ether, the solution passed through a filter which has previously been dried, and weighed in a weighing-bottle, and the maceration of the milk solids is continued with eight successive quantities of ether. Before it is quite dry, the residue is transferred, as far as practicable, to the weighing-bottle, the filter-paper, washed free from fat, is replaced in the bottle, and the whole, with the platinum capsule, is dried at 100° C. for three hours, weighed, then heated at 100° C. for a further two hours, and again weighed. From the weight of non-fatty solids thus obtained, 0.00428 gm. is deducted for each c.c. of N/10 solution of strontia used for neutralising the milk. The ethereal solution of the fat is received in small tared flasks, the ether is distilled off, and the dried fat is weighed. For the determination of the ethyl alcohol, 50, 75, or 100 grms.

of the milk are distilled, the distillate is neutralised with N/10 solution of sodium hydroxide, redistilled, and sp. gr. of the distillate, diluted to a convenient density, determined in a 50-grm. pycnometer. The percentage by weight of alcohol, multiplied by $\frac{3}{2}$ gives the percentage amount of lactose which has disappeared in the production of the alcohol. For the determination of volatile acid, 10 grms. of the milk, contained in a platinum capsule, are neutralised to the extent of one-half of total acidity with N/10 solution of sodium hydroxide, and a little phenolphthalein is added. The mixture is evaporated to dryness on the water-bath with frequent stirring, and after treatment with about 20 c.c. of boiled distilled water, the solution is neutralised with N/10 solution of sodium hydroxide. The difference between the original acidity of the milk and that of the evaporated portion may, in most cases, be regarded as acetic acid. The production of each molecule (60 parts) of this acid denotes a loss of 62 parts of the original lactose. In relatively infrequent cases where the butyric stage of fermentation has become pronounced, the volatile acids are separated by distillation from the quantity of milk which has been taken for the determination of the alcohol. A portion of the mixed aqueous acids is neutralised with barium hydroxide solution, evaporated, and the residue dried. From the percentage of barium contained in mixed salts, the proportions of the two acids are calculated. Each molecule (88 parts) of butyric acid for instance indicates a loss of 92 parts of lactose. To determine small quantity of ammonia formed, 2 grms. of the milk are made up to 100 c.c. with distilled water free from ammonia, and filtered through a carefully-washed filter. In 10 c.c. of the clear filtrate diluted to 50 c.c. with distilled water, the ammonia is determined by Nessler's method, a solution of ammonium chloride containing 0.01 mgrm. of ammonia per c.c. being used as a standard.—A.

Cane Sugar in the Presence of Milk Constituents; Inversion of —. F. Watts and H. A. Tempany. *Analyst*, 1905, 30, 119–123.

THE authors find that solutions of cane sugar containing whey are not completely inverted by citric acid when boiled for ten minutes only. To obtain satisfactory results, the boiling should be continued for 40 minutes. The retarding influence is not due to the lactose, the latter having no effect on the rate of inversion of cane sugar, but to some other constituent of the milk. It is further shown that citric acid does not invert lactose even after boiling for two hours.—W. P. S.

Salicylic Acid in Foodstuffs; Colorimetric Determination of —. F. T. Barry and W. R. Mummery. *Analyst*, 1905, 30, 124–127.

THE method is based upon the fact that lead tannate is insoluble in alkalis, whilst lead salicylate is readily soluble. In the case of jam, fruit pulp, or the like, 50 grms. of the crushed sample are placed in a 300 c.c. flask, a little water is added, then 15 to 20 c.c. of a saturated solution of lead acetate, and the whole rendered alkaline by the addition of about 25 c.c. of sodium hydroxide solution (40 grms. per litre). From 15 to 20 c.c. of approximately N/1 hydrochloric acid solution are now added, and the mixture diluted to the mark. The partial neutralisation of the alkali is necessary to obtain complete solution of the lead salicylate. The contents of the flask are filtered, 200 c.c. of the filtrate are acidified with hydrochloric acid, again filtered if necessary, and extracted three times with ether. The ether is distilled off, the residue of salicylic acid dissolved in a little alcohol, made up to a volume of 100 c.c., and determined colorimetrically with ferric chloride. Alcoholic liquors must be boiled, after the addition of alkali, to remove the alcohol, and the residue then neutralised, before proceeding with the determination.—W. P.

Saccharin [Benzoyl Sulphonic Imide]; Determination of —. C. Proctor. *Chem. Soc. Trans.*, 1905, 7, 242–249.

THE author finds that Reid's process for the determination of saccharin (this J., 1899, 868) gives accurate results.

analysis of commercial saccharin, salts of saccharin, and salts containing saccharin, and the intermediate products obtained in the manufacture of saccharin. In the course of the investigation, it was observed that real saccharin [o-benzoyl sulphonic imide] and para-saccharin [p-benzoyl sulphonic imide] liberate iodine quantitatively in a solution containing potassium iodide and iodate, the following method for the determination of the two isounds has been based on this fact. When the sample consists only of the uncombined ortho-saccharin, or without admixture of p-saccharin and traces of sulphonic-amides, 0.5—1 gram. is weighed into a tared flask, and treated with 50—75 c.c. of recently distilled water, a crystal or two of potassium iodide and 10 c.c. of a 5 per cent. solution of potassium iodate. The mixture is agitated until the saccharin has been freed and the liberated iodine is then titrated with a solution of sodium thiosulphate. The number of c.c. of thiosulphate solution required multiplied by 3 expresses the result as grms. of real saccharin. To obtain the amount of p-benzoyl sulphonic imide, the number of c.c. of N/10-acid required to neutralise the iodine produced in Reid's process (see above) from an equal weight of the sample, must be subtracted from the number of c.c. of N/10-solution of thiosulphate; the difference multiplied by 0.0201 gives the weight of the para-saccharin in grms. In the case of samples containing an admixture of carbonate or consisting of the ammonium or sodium salt of saccharin, 0.5—1 gram. of substance contained in a small capsule is heated on the steam-bath with about 10 c.c. of pure concentrated hydrochloric acid, until the acid is removed, and the residue dried for about 24 hours, and then treated with potassium iodide and iodate as before.—A. S.

IV.—SCIENTIFIC & TECHNICAL NOTES.

Aluminium Chloride Catalysts ["Ferments"]; *Combinations of — with Hydrocarbons and with Hydrogen Chloride*. G. Gustavson. *Comptes rend.*, 1905, 140, 1—941.

INVESTIGATING his studies on the aluminium chloride catalysts "ferments" (see this J., 1903, 713) which are produced by the combination of aluminium chloride with benzene or in alkyl chloride, the author finds that these bodies possess the property of combining simultaneously with hydrocarbons and with hydrogen chloride. When isopropyl chloride is added gradually to a mixture of aluminium chloride and finely powdered aluminium chloride at a low temperature, the reaction is completed in two stages:— according to the equation: $\text{Al}_2\text{Cl}_6 + 2\text{C}_6\text{H}_6 + 3(\text{CH}_3)_2\text{CHCl} = \text{Al}_2\text{Cl}_6\text{C}_6\text{H}_5[(\text{CH}_3)_2\text{CH}]_3\text{C}_6\text{H}_5 + 3\text{HCl}$ the first stage being a combination of the "ferment" with benzene, and remaining liquid.

In the addition of more isopropyl chloride, according to the equation:

the product solidifying to a yellow crystalline mass composed of a combination of the "ferment" with triisopropyl benzene and hydrogen chloride.

This yellow compound is dissociated on heating at 55° C. into two layers, the lower layer consisting of the regenerated "ferment," and the upper layer of triisopropyl benzene, hydrogen chloride being evolved.

The yellow combination can be re-formed by saturating a mixture of the "ferment" and the hydrocarbon with hydrogen chloride at a temperature of -10° C. Analogous combinations are produced when other alkyl chlorides or substituted benzenes are employed. It is also possible to obtain mixed compounds of the same character.—J. F. B.

Glycerol; *Esterification of —*. M. P. S. Guédrias. *Comptes rend.*, 1905, 140, 1034.

In the course of the manufacture of plastic masses composed of casein with the addition of acetic acid and glycerin,

the glycerin being in excess, the author has observed the formation of glycerol monoacetate. The formation of the ester is very rapid, even in the cold, and the rapidity of the reaction can only be attributed to catalytic influence. It is suggested that the casein, owing to its porous structure, plays the part of a "contact" catalyst.—J. F. B.

Dextrose; *Conversion of — into Methylimidazole*. A. Windaus and F. Knoop. *Ber.*, 1905, 38, 1166—1170.

UNDER the action of dilute alkali, dextrose undergoes a series of transformations, leading to the formation of hydroxy-acids such as lactic acid. The authors find that, although ammonia acts only very slowly on dextrose, the latter is readily attacked by zinc hydroxide-ammonia or by other metallic hydroxides which do not form complex compounds with ammonia, e.g., potassium hydroxide and ammonia, the main product in all cases being (α- or β-) methyl-imidazole (methylglyoxaline). An appreciable quantity of saccharin is also formed.—T. H. P.

Carbohydrates; *Action of Hydrogen Peroxide on — in presence of Ferrous Sulphate*. R. S. Morrell and A. E. Bellars. *Chem. Soc. Trans.*, 1905, 87, 280—293.

IN continuation of their previous work (this J., 1902, 506; 1903, 1371; 1904, 993), the authors find that the acidities of the sugar solutions after oxidation are insufficient to account even for the complete formation of one monobasic hexose acid. The greater the acidity of the solution, the smaller was the yield of osazone precipitated by phenylhydrazine in the cold. Among the oxidation products of arabinose and rhamnose, formic and oxalic acids were detected, but the more important ketone-acids which were expected could not be isolated, although qualitative tests seem to leave little doubt of their presence. The authors succeeded in preparing arabinosone from arabinose, and rhamnosone from rhamnose by Fischer's method (this J., 1902, 1302), and also, by using o-nitrobenzaldehyde in place of benzaldehyde, dextrosone and rhamnosone from dextrosazone and rhamnosazone respectively. Radium emanations were found to have no influence on the oxidation of carbohydrates.—A. S.

Levulose and Dextrose; *Influence of Inorganic Substances on the Rotation of —*. E. Rimbach and O. Weber. *Z. physik. Chem.*, 1905, 51, 473—493.

THE influence of inorganic bodies, belonging to various groups of the periodic system, on the rotatory powers of dextrose and levulose is, as a general rule, inconsiderable. The increase of rotatory power, which is observed in the case of optically active hydroxy acids and polyhydric alcohols by the action of compounds of arsenic, molybdenum and uranium, does not occur in the case of dextrose and levulose. Zirconium salts and substances which liberate hydroxyl ions by dissociation have a more considerable influence on the rotatory powers of these sugars; this is due, however, to the decomposition of the sugar molecule. The velocity of this decomposition, in the case of the action of certain free alkalis and hydrolysed salts on dextrose, is, other conditions being constant, proportional to the concentration of the hydroxyl ions. The chlorides of the elements of the second group of the periodic system cause a considerable increase of the rotatory powers, especially with levulose; compounds of cerium and thorium do the same. The influence of the same inorganic substance on the rotations of the two sugars is sometimes in the same direction and sometimes in an opposite direction. Levulose is generally more sensitive than dextrose. The majority of the changes in rotation observed were due, not to chemical combination, but rather to the influence of the salt on the degree of asymmetry of the active molecule. Only in a few cases, e.g., boric acid, is the conductivity of the inorganic solution increased by the addition of the sugar; it is generally decreased.

—J. F. B.

Sugar Groups in Hydrocarbons; *Reciprocal Replacement of —*. E. Votocek and E. Vondracek. *Ber.*, 1905, 38, 1093—1095.

The authors have recently shown that the hydrazine

residue of the hydrazone of a sugar can be replaced by the action of a suitable substituted hydrazine. From this it would appear that one sugar may replace another from its hydrazone, provided that the newly-formed hydrazone is less soluble than the original one. This supposition has been experimentally verified, and it is found that the replacement is accelerated if the solution (in water or dilute alcohol) is slightly acidified with acetic acid. With the diphenylhydrazones, actual deposition of the less soluble compound takes place only after the addition of acetic acid. Further, if two differently substituted hydrazones of two different sugars act upon one another, the least soluble of the four possible hydrazones separates out, the reaction being represented by: $A_1B_1 + A_2B_2 = A_1B_2 + A_2B_1$. The authors' experiments have been made with: (1) galactophenylhydrazone and arabinose, which yield mannophenylhydrazone and galactose; (2) dextro-methylphenylhydrazone and galactose, which form galactomethylphenylhydrazone and dextrose; (3) dextro-diphenylhydrazone and arabinose, which give arabinose-diphenylhydrazone; and (4) galactodiphenylhydrazone and dextro-methylphenylhydrazone, yielding galactomethylphenylhydrazone and dextro-phenylhydrazone.—T. H. P.

Prizes.

New Method of Diamond Cutting Wanted.
"Times," April 17, 1905.

The Home Secretary has received, through the Foreign Office, information of a competition instituted by the Government of the Netherlands for the purpose of discovering a new method of diamond cutting which shall do away with the danger of lead poisoning, either by the provision of a new medium for the setting and resetting of diamonds to be cut or by the substitution of a different plan of work. The medium or method must be (a) practicable for all sizes and shapes of diamonds in the following branches of the diamond industry:—*viz.*, brilliants, roses, and so-called non-recoupes, now being cut in the Netherlands; (b) such that its use can be learned by the workmen accustomed to the present method of work, without any great difficulty; (c) such that its use will not entail much more time, or considerably greater expense than is usual under present conditions. The Minister of the Interior has appointed a committee of experts to consider the answers submitted, and to award the prize. The answers may be written in English and must be accompanied by samples or objects to enable the committee to form an opinion about the practical value of the invention; also by a legibly written address of the competitor. The answers and the samples or objects must be sent, carriage paid and duty paid, before January 1, 1906, to Professor Dr. L. Aronstein, chairman of the committee, chemical laboratory of the Polytechnic School, Delft, Holland. The prize to be awarded for a complete solution of the problem is 6,000 florins. The committee is empowered to divide the prize among different competitors or to award part of the prize in case of a partial solution of the problem. The committee is also empowered to prescribe certain conditions to be fulfilled by the competitor, before awarding the prize.

New Books

DIE CHEMIE AUF DER Weltausstellung zu St. Louis, 1904. von Dr. Walter Vieweg. Sonderausgabe aus der Sammlung Chemischer und Chemisch-technischer Vorträge. Herausgegeben von Prof. Dr. Felix B. Ahrens. Bd. X. F. Enke, Stuttgart, 1905. Price M. 2.40.

HYPOCHLORITE UND ELEKTRISCHE BLEICHE. 2. chemischer Theil. Theorie der Elektrochemischen Stellung von Bleichlauge. von Dr. EMIL A. WILHELM Knapp's Verlag. Halle a. S. 1905. M. 4.50.

Two volume, containing 110 pages of subject matter and an index of names. The pages are illustrated with curve tables and 10 tables of figures, and are devoted to the following subjects:—I. Introduction, concerned with the ions of H, OH, O, Na, Cl, ClO and ClO₂. II. Theoretical consumption of Power. III. Mechanism of Production of the ion ClO. IV. Decomposition potential of NaCl solution. V. Reactions of Superposition. Analytically formulating the Dependence of Chlorine on the Duration of Electrolysis. VII. Consumption of Salt. VIII. Mechanism of the Bleaching Process. IX. Conditions for a high degree of Chlorine Effect. X. The Electrodes.

FORTSCHRITTE IN DER FABRIKATION DER ANORGANISCHEN SAUREN, DER ALKALIEN, DES AMMONIAKS, UND VERWANDTER INDUSTRIEZWEIGE. An der Hand der mathematisch geordneten Patentliteratur. Dargestellt von VICTOR HÖBLEING, K. K. technischem Rath, ständ. Mitglied des K. K. Patentamtes, &c. 1895—1905. Julius Springer's Verlag, Berlin. 1905. Price 2 Mk. Bound, M. 32.40.

QUARTO volume containing 753 pages of subject matter and alphabetical indexes of names and subjects. The work is quite similar in character to that of I. Friedländer on "Die Fortschritte der Theoriefarbenfärbung und verwandter Industriezweige," consisting of a classified collection of abstracts of German patents granted and issued between the years 1895—1903, relating to the Manufacture of Inorganic Acids, Alkalis and Ammonia and to Allied Branches of Chemical Industry. In this work of illustrated patent specifications, the illustrations reproduced in these abstracts. The work is divided into two parts:—PART I. dealing with Sulphur and the Sulphuric Acid, Nitric Acid and Nitrites, and Hydrochloric Acid. PART II. Sodium Carbonate (Soda Ash and Crystals), Bicarbonate and Carbonic Acid, Caustic Soda, Chlorine, Hypochlorites and Chlorates, Ammonia. Index of the numbers of German Patents is given at the end of the work, the numbers being given in order, the pages of the work on which the corresponding abstracts appear.

INDUSTRIAL ALCOHOL COMMITTEE. MINUTES OF EVIDENCE. [Cd. 2477.] Price 2s. 4d.

This publication contains minutes of the evidence given before the Departmental Committee on Industrial Alcohol and appendixes showing the duties and allowances on British spirits and duties on foreign spirits; regulations for its use for industrial purposes in the United Kingdom, United States, and in the principal European countries; together with an abstract of the approximate quantities of unmineralised methylated spirits used in manufacturing operations, &c., in the United Kingdom during 1901, a comparative table of the quantity of spirits, &c., in making methylated spirits, and of the methylated spirits produced for the five years ending March 31, 1901. (This J., 1905, 397—426).

Trade Report.

I.—GENERAL.

GERMAN TARIFF AS MODIFIED BY TREATIES; NEW EDITION. [Cd. 2414] 1905. Wyman and Sons, Fetter Lane, E.C. Price 1s. 10d.

The following statement shows the instances in which modifications, of interest to Chemical Industry, have been made in the rates of duty under the "General Tariff" and under the modified "Conventional Tariff" (which comes into force on March 1, 1906):—

	Classification under New "General" Tariff.	Existing Tariff.	"General" Tariff.	Conv. arial Tariff (Modified)
	<i>Class I.—Forest Products.</i>	m.pfg.	m pfg.	m.pfg.
92	Tanning bark, ground up or not	free	100 kilos.	free
93	Quebracho wood and other tanning woods in blocks, also ground up, grated or otherwise broken up	free	100 kilos.	7.00
	Sumach, ground or not	free	100 kilos.	3.00
94	Galls and gall-nuts, ground or not	free	100 kilos.	3.00
	Algarobilla, bablah, dividivi, valonia, acorn-cups, myrobalans and other tanning materials not separately distinguished, whether ground or not; cutch, brown and yellow (gambier), raw or refined; kino	free	100 kilos.	3.00
	<i>Class I.—Products of Oil Milling, &c.</i>			
95	Fatty oils, in casks—			
	Olive oil, pure	100 kilos. 3.00	100 kilos. 10.00	free
	"Lavat" and "sulphur" oils	100 kilos. 3.00	100 kilos. 2.00	free
	Castor oil	100 kilos. 2.00	100 kilos. 9.00	100 kilos. 2.00
	Other fatty oils	100 kilos. 9.00	100 kilos. 10.00	100 kilos. 9.00
96	Fatty oils in receptacles other than casks—			
	Olive oil, pure	100 kilos. 10.00	100 kilos. 20.00	100 kilos. 10.00
	Castor oil in tin receptacles, weighing with the tin, at least 15 kilos.	100 kilos. 2.00	100 kilos. 20.00	100 kilos. 2.00
97	Oleic acid (oleine)	100 kilos. 3.00	100 kilos. 3.00	100 kilos. 3.00
98	Oil dregs	100 kilos. 4.00	100 kilos. 4.00	100 kilos. 4.80
	<i>Starch Products.</i>			
99	Starch, green or dry, ground or not	100 kilos. 12.50	100 kilos. .00	100 kilos. 14.00
	<i>Products of Food Industries.</i>			
00	Margarine	100 kilos. 16.00	100 kilos. 13.00	100 kilos. 20.00
	<i>Class II.—Mineral Oils.</i>			
01	Petroleum, fluid natural mineral tar, brown-coal tar oil, peat oil, shale oil, oil from the tar of bog head or cannel coal, and other mineral oils not otherwise enumerated, crude or refined—			
	Lubricating oils, residues from the distillation of mineral oils, containing paraffin or of a tarry or pitchy nature—the latter provided they do not sink in water; rosin oil	100 kilos. 10.00	100 kilos. 10.00	100 kilos. 6.00
02	Other oils—			
	Heavy benzine of a sp. gr. of more than 0.75 up to 0.77, inclusive, at 15° C., for driving motors	100 kilos. 6.00	100 kilos. 6.00	100 kilos. 2.00
	Gas oil of a sp. gr. of 0.83 to 0.88, inclusive, at 15° C., for driving motors or for the carburation of hydrogen	100 kilos. 6.00	100 kilos. 6.00	100 kilos. 3.00
	<i>Class III.</i>			
03	Mineral wax (ozokerit) refined, and ceresine (made from mineral wax, mixed or not with paraffin); wax stumps of refined mineral wax and of ceresine	100 kilos. 10.00	100 kilos. 15.00	100 kilos. 10.00
04	Soft paraffin	100 kilos. 10.00	100 kilos. 10.00	100 kilos. 8.00
05	Turkey red oil, in casks	100 kilos. 5.00	100 kilos. 5.00	100 kilos. 3.00
06	Paraffin ointment, vaseline, and vaseline ointment	100 kilos. 10.00	100 kilos. 12.00	100 kilos. 10.00
07	Axle grease	100 kilos. 3.00	100 kilos. 10.00	100 kilos. 6.00
08	Other lubricants, manufactured with fats or oils, liquid or solid	As component materials or those most highly taxed		100 kilos. 12.00
	<i>Class IV.</i>			
09	Tartaric acid	free	100 kilos. 8.00	100 kilos. 4.00
10	Citric acid	free	100 kilos. 3.00	free
11	Spring salts, natural or artificial and marsh salts	free	100 kilos. 2.00	free
12	Potash of all kinds, also wool yolk ash	100 kilos. 1.50	100 kilos. 0.25	100 kilos. 1.50
13	Sodium sulphate and bisulphate	free	100 kilos. 2.00	free
14	Copper sulphate	free	100 kilos. 6.00	100 kilos. 2.00
15	Stannic oxide	free	100 kilos. 1.00	100 kilos. 1.00
16	Calcium acetate	free	100 kilos. 8.00	100 kilos. 4.00
17	Other acetates and acetone oil	free	100 kilos. 8.00	100 kilos. 4.00
18	Tartar, refined	free	100 kilos. 4.00	free
19	Tartar emetic and other preparations of antimony	free	100 kilos. 4.00	100 kilos. 4.00
20	Calcium carbide	free	100 kilos. 4.00	100 kilos. 4.00
21	Other carbides	free	100 kilos. 1.00	free
22	White lead	free	100 kilos. 2.00	free
23	Zinc oxide and lithopone	free	100 kilos. 0.40	100 kilos. 0.20
24	Chalk, washed	free	100 kilos. 0.50	free
25	Iron oxide	free	100 kilos. 0.50	100 kilos. 0.20
26	Other mineral colours	free	100 kilos. 1.00	100 kilos. 2.00
27	Graphite (in blocks)	100 kilos. 2.00	100 kilos. 6.00	100 kilos. 3.00
28	Graphite (made up for sale)	free	100 kilos. 5.00	free
29	Wood spirit and acetone, crude (strength not exceeding 95%)	100 kilos. 20.00	100 kilos. 30.00	100 kilos. 20.00
30	Vol. oil of oranges, bergamot, &c.	100 kilos. 20.00	100 kilos. 30.00	100 kilos. 20.00
31	Aniseed oil	free	100 kilos. 10.00	100 kilos. 6.00
32	Cassia	100 kilos. 3.00	100 kilos. 5.00	100 kilos. 3.00
33	Glue (solid)	free	100 kilos. 14.00	free
34	Gall and sumach extracts	free	100 kilos. 14.00	100 kilos. 2.00
35	Oak, pine, or chestnut extracts—			
	Liquid	free	100 kilos. 28.00	100 kilos. 4.00
36	Solid	free	100 kilos. 28.00	100 kilos. 8.00
37	Other tanning extracts—			
	Liquid	free	100 kilos. 28.00	100 kilos. 8.00
	Solid	free	100 kilos. 28.00	100 kilos. 8.00
	<i>Class XI.</i>			
38	Paper stock from wood, straw, esparto, &c., mechanical or chemical	100 kilos. 1.00	100 kilos. 3.00	100 kilos. 1.25
	<i>Class XIV.</i>			
39	Crucibles, retorts, muffles, capsules, tubes, cylinders, slabs, blast pipes	100 kilos. 1.50	100 kilos. 2.00	100 kilos. 1.50
40	Other shaped fireproof products of clay and clayey substances other than bricks, glazed or not	100 kilos. 2.00	100 kilos. 2.00	100 kilos. 1.50
41	Crucibles of magnesite cement or soapstone	100 kilos. 6.00	100 kilos. 2.00	100 kilos. 1.50

BRAZIL; EXPORT TRADE OF — IN 1904.

Bd. of Trade J., April 27, 1905.

The following figures, showing the quantities and values

of certain articles exported from Brazil during the 1904, with corresponding figures for the preceding are extracted from the *Brazilian Review* of 28th Mar

III.—TAR PRODUCTS, PETROLEUM, Etc.

OZOKERITE.

Eng. and Mining J., April 13, 1905.

The principal producing district in the world is Galicia, where in 1904 a total of 29,8 tons was mined from the oil-bearing shale in Boryslav and the neighbourhood. A large part of this output was exported to the United States, where crude ozokerite sells at 11.5c. per lb., and refined (ceresin) at 13.5 to 16.5c. per lb., according to quality. The consumption is centred chiefly in the manufacture of candles, ointments and pomades. Under the name of "okonite," a residual product from purifying the crude ozokerite, is an admirable insulating material for electrical cables. For this purpose the ozokerite residuum is mixed with india-rubber. Some shoe blacking is also made from ozokerite, because it gives a glossy surface.

ACETONE; MANUFACTURE OF — IN INDIA.

Chem. and Drug., April 29, 1905.

The manufacture of acetone in India from locally-grown blue gum wood is being taken up by the military authorities. Acetone is the solvent used in the manufacture of cordite at the Government cordite factory at Wellington, in Southern India, and has at present to be imported at a great cost. A large consignment of the Indian timber was sent home early last year for purposes of distillation, and the satisfactory results obtained show that the manufacture of acetone in India is a perfectly feasible project.

IV.—COLOURING MATTERS, Etc.

CALICO YELLOW G AND CHROME GREY R. B. G.: U.S. CUSTOMS DECISIONS.

April 13, 1905.

Calico Yellow G, a mixture of alizarin and aniline dyes, and Chrome Grey R.B.G., a mixture of logwood extract and aniline dye in acetic acid, were held to be dutiable at 30 per cent. *ad valorem* as "coal tar colours," under paragraph 15 of the tariff.

The claims of the importers that the Calico Yellow G. was free of duty under paragraph 469 as a "dye derived from alizarin" and that the Chrome Grey R. B. G. was dutiable under paragraph 22 as an "extract of logwood" were overruled on the ground that the aniline dye was the component material of chief value in each case.—R. W. M.

VII.—ACIDS, ALKALIS, Etc.

SALT PRODUCTION OF SPAIN IN 1904.

U.S. Cons. Rep. No. 2223, April 3, 1905.

The salt industry of Spain is daily extending its sphere of operation, and besides supplying domestic wants, estimated at 369,000 tons yearly, exports considerable quantities, amounting in 1904 to 350,000 tons, an increase

of 71,729 and 58,584 tons since 1902 and 1903, respectively. This production admits, however, of a still better development, if the public authorities help to keep the clear of all encumbrances. The industry, placed a new basis, governed by modern systems and processes is capable, no doubt, of having an era of prosperity before experienced by it.

There are in Spain to-day 209 concessions of rock works, extending over an area of 6,803 acres, of which number 54 are in operation and 155 are idle. The territory covered by the former is 2,385, by the latter 4,418.

Spanish production of salt compared with that of the rest of the world ranks sixth in importance, being exceeded by that of the United States, England, Germany, France and Austria-Hungary.

So far Spanish salt has been admitted into the markets of Uruguay, Newfoundland, Russia, Argentina, Brazil, France, Cuba, Norway, Belgium, England, Netherlands, and countries of minor importance, it is regarded as unequalled for salting and tanning.

The salt works of Cadiz alone have contributed 3,322,622 tons, or 221,657 tons, toward the total export of 1904, other parts participating with 128,349 tons. The average production of the sea-salt pans is 300,000 tons, a quantity which could be much increased if certain alterations were made and certain tracts now lying idle were made to produce. Two thousand labourers within the radius of this industrial region, and the goods distributed among them amount to 236,250 dols. yearly.

X.—METALLURGY.

PIG IRON PRODUCTION; BRITISH —.

Eng. and Mining J., April 13, 1905.

The total production of pig iron in Great Britain in 1904 was given in the *J.*, of April 29, pp. 463-4. The figures in detail are given in the table below, in long tons:—

	1903.	1904.
	Tons.	Tons.
Forge and foundry	3,875,826	3,841,111
Hematite	3,760,422	3,362,111
Basic	991,610	1,192,111
Spiegel and ferro	183,346	165,111
Totals	8,811,204	8,560,443

Basic is the only grade of iron showing an increase. In Scotland, Cleveland, Lincolnshire, North Staffordshire, Shropshire, Nottingham and Leicestershire and in Wales there was an increase of output, while in Durham, West Cumberland and Lancashire, South Wales and Monmouth, Northamptonshire, Derbyshire, South Staffordshire, and South and West Yorkshire there was a decrease.

IRON ORE OUTPUT OF GERMANY.

U.S. Cons. Rep. No. 2227, April 8, 1905.

The gross production of iron ore in the year 1904

any and the Grand Duchy of Luxemburg amounted 103,941 metric tons, against 10,085,634 metric tons in 1903. The yield of the ore-bearing regions varied considerably in the two years. In the Kingdom of Saxony no ore whatever was mined in 1904. The slight gain in gross output of the year was entirely made during the month of December, 1904, and lifted the past year's production as to productiveness.

TANTALUM MINERALS; OCCURRENCE OF—

Day, *Electrochem. and Met. Ind.*, 1905, 3, 133-134.

A review of the important development of the tantalum by Siemens und Halske of Berlin, the author has added information as to the occurrence of these minerals

in the United States. Llano County, Texas, where *Jergusonite* is found, Mitchell County and other neighbouring localities in North Carolina where mica is mined and further Rockport, Massachusetts, where *columbite* was first discovered are considered the most promising. Attention is directed to the residues from Greenland cryolite which may contain some quantity of these minerals.—R. S. H.

MINERAL PRODUCTION OF GERMANY IN 1904.

Bd. of Trade J., April 20, 1905.

According to an advance statement of the Imperial Statistical Bureau showing the mineral and metallurgical production of the German Empire for the year 1904, the output of coal in that year was as follows, the corresponding figures for 1903 being added for purposes of comparison:—

	1903.		1904.	
	Quantity.	Value.	Quantity.	Value.
	Metric Tons.	Thousand Marks.	Metric Tons.	Thousand Marks.
.....	116,637,765	1,005,153	120,815,503	1,034,000
.....	45,819,488	107,412	48,632,769	111,999
Total	162,457,253	1,112,565	169,448,272	1,145,999

The following table shows the quantity and value of other minerals and salts produced in the years 1903 and 1904:

	1903.		1904.	
	Quantity.	Value.	Quantity.	Value.
	Metric Tons.	Thousand Marks.	Metric Tons.	Thousand Marks.
.....	21,230,650	74,235	22,047,297	76,668
.....	682,853	33,058	715,732	39,479
.....	165,991	14,084	164,440	14,708
.....	772,695	20,449	798,214	21,731
.....	11,467	1,245	10,405	1,206
.....	14,607	819	14,016	925
.....	47,994	520	52,886	591
.....	170,867	1,319	174,782	1,336
.....	87,454	812	91,736	891
.....	60,743	4,184	89,606	5,804
.....	1,095,541	5,056	1,079,868	5,001
.....	1,557,243	21,883	1,905,893	26,565
.....	2,073,720	20,981	2,179,471	21,295

The products of reduction works are stated to be as follows:—

	1903.		1904.	
	Quantity.	Value.	Quantity.	Value.
	Metric Tons.	Thousand Marks.	Metric Tons.	Thousand Marks.
.....	31,214	37,841	30,262	36,304
.....	182,548	73,921	193,058	84,650
.....	145,319	33,490	137,580	32,546
.....	4,428	1,105	4,332	1,117
.....	10,017,901	525,007	10,058,273	520,647

The production of refined salt, and of various salts, in refined or commercial form, is shown in the following table:—

	1903.		1904.	
	Quantity.	Value.	Quantity.	Value.
	Metric Tons.	Thousand Marks.	Metric Tons.	Thousand Marks.
.....	598,394	14,184	621,064	14,697

Birmingham Section.

Chairman: Percy F. Frankland.

Vice-Chairmen:

W. Waters Butler, Frank E. Lott, Alex. F. Tucker.

Committee:

Robt. B. Batty.	Edward Jackson.	T. Slater Price.
Wm. B. Davidson	Thos. Lawton.	Walter Rosenhain.
Alex. Findlay.	Alex. McKenzie.	Harry Silvester.
Henry L. Heathcote.	Frank Platten.	Thos. Turner.

Hon. Local Secretary and Treasurer:

F. R. O'Shaughnessy, Tyburn, nr. Birmingham.

Canadian Section.

Chairman: F. J. Smale.

Vice-Chairmen: W. H. Ellis, Thos. Macfarlane.

Committee:

J. Watson Bain.	W. L. Goodwin.	W. Lash Miller.
Jeffrey H. Burland.	W. R. Lang.	Jas. P. Murray.
Thos. Davies.	A. McGill.	Harold Vander Linde.
G. P. Girdwood.		

Hon. Treasurer: M. J. Taylor, 77, Front Street East, Toronto

Hon. Local Secretary:

Alfred Burton, 42, Front Street West, Toronto.

Liverpool Section.

Chairman: Eustace Carey.

Vice-Chairman: Frank Tate.

Committee:

T. Lewis Bailey.	G. Watson Gray.	Al. Smetham.
G. C. Clayton.	C. Longuet Higgins.	H. B. Stocks.
J. T. Conroy.	Max Muspratt.	J. W. Towers.
A. Foden.	E. L. Peck.	

Hon. Treasurer: W. P. Thompson.

Hon. Local Secretary:

W. R. Hardwick, 13, Batavia Buildings, Rackins Hey, Liverpool.

The following take office in July next:—*Committee:* Arthur Carey, J. Campbell Brown, Herbert E. Davies, and W. Collingwood Williams.

London Section.

Chairman: A. Gordon Salamon.

Vice-Chairman: R. J. Friswell.

Committee:

H. G. Colman.	D. L. Howard.	Walter F. Reid.
J. N. Connah.	J. Leckowitsch.	L. T. Thorne.
Bernard Dyer.	A. R. Ling.	Thos. Tyrer.
Oscar Guttman.	Wm. Pearce.	Chas. Wightman.
J. T. Hewitt.	Boverton Redwood.	

Hon. Local Secretary:

Julian L. Baker, 7, Addison Road, Bedford Park, W.

The following take office in July next:—*Committee:* E. J. Bevan, M. O. Forster, G. C. Jones, B. E. R. Newlands, and F. Napier Sutton.

Manchester Section.

Chairman: J. Carter Bell.

Vice-Chairman: F. Scudder.

Committee:

J. Allan.	G. J. Fowler.	K. Markel.
J. Blliger.	J. Grossmann.	W. J. Pope.
R. Clayton.	B. Hart.	H. Porter.
W. H. Coleman.	W. B. Hart.	W. Thomson.

Hon. Local Secretary:

Julius Hübner, Ash Villa, Cheadle Hulme, Cheshire.

The following take office in July next:—*Chairman:* G. H. Bailey. *Committee:* J. Barnes, R. S. Hutton, W. E. Kay, J. H. Lester, and F. Stenhouse.

Newcastle Section.

Chairman: J. T. Dunn.

Vice-Chairman: W. L. Rennoldson.

Committee:

P. P. Bedaon.	N. H. Martin.	Harry Smith.
H. S. Collins.	John Pattinson.	A. Spiller.
Ellwood Holmes.	W. W. Proctor.	J. E. Stead.
H. Louis.	Geo. Sisson.	C. E. Stuart.

Hon. Local Secretary and Treasurer:

F. C. Garrett, Armstrong College, Newcastle-on-Tyne.

The following take office in July next:—*Chairman:* H. Louis. *Vice-Chairman:* J. T. Dunn. *Committee:* W. L. Rennoldson.

New England Section.

Chairman: Henry Howard.

Committee:

F. E. Atteaux.	A. F. Hobbs.	A. Renterdal.
C. R. Borland.	J. W. Loveland.	F. C. Robins.
A. A. Claffin.	L. A. Olney.	F. H. Thorp.
W. A. Gallup.	Edw. D. Pearce.	W. J. Webb.

Hon. Local Treasurer: Godfrey L. Cabot.

Hon. Local Secretary:

Wm. H. Walker, 93, Broad Street, Boston, Mass., U.S.

New York Section.

Chairman: Russell W. Moore.

Vice-Chairman: Geo. C. Stone.

Committee:

L. Backeland.	A. H. Elliott.	Wm. H. Nieb.
Chas. Baskerville.	E. G. Love.	T. J. Parker.
Chas. F. Chandler.	Wm. McMurtrie.	F. Schiewind.
V. Coblentz.	H. A. Metz.	C. B. Zabrick.
G. Drobegg.		

Hon. Treasurer: R. C. Woodcock.

Hon. Local Secretary:

H. Schweitzer, 40, Stone Street, New York, U.S.A.

The following take office in July next:—*Committee:* Laguel Haigh, A. C. Humphreys, Edmund H. Miller, Prochazka, and Walter E. Rowley.

Nottingham Section.

Chairman: J. T. Wood.

Vice-Chairman: S. P. Burford.

Committee:

L. Archbutt.	F. Stanley Kipping.	A. L. Stern.
F. J. R. Carulla.	H. B. Mayfield.	G. J. Ward.
R. M. Caven.	J. O'Sullivan.	J. White.
J. Golding.	J. M. C. Paton.	

Hon. Treasurer: S. J. Pontecot.

Hon. Local Secretary:

S. R. Trotman, King's Walk Chambers, Parliament Street, Nottingham.

The following take office in July next:—*Chairman:* J. L. Paton. *Vice-Chairman:* J. T. Wood. *Committee:* Burford, H. S. Garry, and O. Quibell.

Scottish Section.

Chairman: R. T. Thomson.

Vice-Chairman: J. S. Macarthur.

Committee:

W. S. Curphey.	G. H. Gemmell.	W. G. Johnst.
L. Dobbin.	R. Hamilton.	J. Falconer.
D. B. Dott.	Jas. Hendrick.	M. A. Parke.
Thos. Ewan.	Jas. Hope.	T. L. Patters.
J. Arnold Fleming.	H. Ingle.	D. J. Playfair.
W. Frew.		

Hon. Secretary and Treasurer:

Thomas Gray, c/o Gourlay and Deas, 180, Hope Street, Glasgow.

The following take office in July next:—*Chairman:* Perry. *Committee:* Robt. M. Clark, Chas. E. Fawcett, Ford, G. G. Henderson and Jas. McLeod.

Sydney, N.S.W., Section.

Chairman: A. Liversidge.

Committee:

W. A. Dixon.	J. Morison.	R. Greig Sm.
J. F. Elliott.	A. A. Ramsay.	H. G. Smith.
L. Meggill.	J. A. Schofield.	T. Steel.

Hon. Local Secretary:

T. U. Walton, Colonial Sugar Co., O'Connell Street, Sydney.

The following take office in July next:—*Committee:* V. G. C. Joplin and J. M. Petrie.

Yorkshire Section.

Chairman: H. R. Procter.

Vice-Chairman: G. W. Slatter.

Committee:

C. S. Bedford.	John W. Cobb.	A. Smithells.
J. E. Bedford.	W. M. Gardner.	Geo. Ward.
F. Branson.	F. W. Richardson.	Thorp White.
B. A. Burrell.		

Hon. Local Secretary and Treasurer:

T. Fairley, 17, East Parade, Leeds.

The following take office in July next:—*Vice-Chairman:* Whitaker. *Committee:* Saml. H. Davies, H. R. Hirst, Mackey and G. E. Scott-Smith.

Official Notices.

COMMUNICATIONS.

ors of communications read before the Society, or its Local Sections, are requested to take notice that Rule 43 of the Bye-laws the Society has the right of publication for three months of all such papers. Payment of this Bye-law renders papers liable to be by the Publication Committee, or ordered to be ted for the Journal, in which case no reprints can lished to the author.

ANNUAL GENERAL MEETING, 1905.

The Annual General Meeting will be held in London next, and the proceedings will commence on July 10th.

In accordance with the provisions of Rule 18 of the Bye-laws, notice is hereby given that those members whose names are printed in *italics* in the list of Council are from their respective offices at the forthcoming Meeting.

Edward Divers, F.R.S., has been nominated to the office of President under Rule 8; Dr. L. Baekeland, Carter Bell, Dr. J. Lewkowitsch, and Mr. N. H. Proudeston have been nominated Vice-Presidents under Rule 11; and Mr. Wm. H. Nichols has been nominated a President under Rule 11.

Hon. Treasurer and Hon. Foreign Secretary have been nominated for re-election to their respective offices. Members are hereby invited to nominate fit and proper persons to fill four vacancies among the ordinary members of Council. Forms for this purpose can be obtained, on application, from the General Secretary, or from the Local Secretaries of the Canadian, New York, and London Sections.

from Rule 18 :—"No such nomination shall be valid unless it be signed by at least ten members of the Society who are not in arrear with their subscriptions, and it shall be received by the General Secretary, at the office, at least one month before the date of the Annual General Meeting, at which the election to which it takes place. Nor shall any such nomination be valid unless the person nominated be ineligible for election under Rules 12 or 15. No member shall sign more than one nomination form."

CONGRESS OF CHEMISTRY AT LIÈGE.

In connection with the Liège Exhibition, a Congress of Chemistry and Pharmacy will be held from the 27th to the 31st of July next. By a subscription of 10 francs, members may take part in the Congress, and will receive the benefit of the transactions. Application for Adhesion and programmes should be made at once to M. J. D. Pharmacie, Liège, or M. J. Wauters, Chimiste à la Ville de Bruxelles.

BIRMINGHAM SECTION.

A list of Committees will be found the names of the Committees of the Birmingham Section which, at intervals of some years, has resumed active work. Meetings will be held at the University, and Prof. W. Frankland, F.R.S., has accepted the chairmanship. Mr. F. R. O'Shaughnessy as Hon. Local Secretary and Treasurer.

NEW ENGLAND SECTION.

The New England Section, a list of the Committee of which will be found on p. 524, held its inaugural meeting in Boston, Mass., on May 12th. Between 80 and 90 members were present, including the President of the Society, Dr. H. Schweitzer, Mr. T. J. Parker, and representatives of the New York Section.

SIXTH INTERNATIONAL CONGRESS OF APPLIED CHEMISTRY, ROME, 1906.

At a meeting of the Organising Committee of the Sixth International Congress of Applied Chemistry, held in Rome on March 2 last, Prof. E. Paternò in the chair, it was decided to divide the Congress into the same number of sections as was the case at Berlin in 1903. At the suggestion of the Presidents of foreign Committees, the date of meeting was fixed for April, 1906, during Easter week.

All communications with respect to the Congress should be addressed to the President, Prof. E. Paternò, Via Panisperna 89, Rome.

List of Members Elected.

May 23rd, 1905.

- Armstrong, Theodore, 115, Chestnut Street, Philadelphia, Pa., U.S.A., President, Penn. Salt Manufacturing Co.
- Barry, Eugene, Ayer, Mass., U.S.A., Leather Manufacturer.
- Bliss, H. J. W., 417, West 118th Street, New York City, U.S.A. (after June 10, Cornwall Gardens, London, S.W.), Student.
- Browning, Prof. R. C., Medical College, Colombo, Ceylon, Professor of Chemistry.
- Clextion, Thomas J., 86, Elm Hill Avenue, Roxbury, Mass., U.S.A., Manager, A. Klipstein and Co.
- Davison, Alex. Young, 396, Atlantic Avenue, Boston, Mass., U.S.A., Dyestuff and Chemical Merchant.
- Dearing, Mark Gordon, Grosvenor Villa, Ashby Road, Canonbury, N., Chemist.
- Dupin, Dr. Eugene, 131, West 53rd Street, New York City, U.S.A., Chemist.
- Durfee, Winthrop C., 190, High Street, Boston, Mass., U.S.A., Manufacturing Chemist.
- Forrester, Harris A., Usina de Gas, Retiro, Buenos Ayres, South America, Chemical Works Manager.
- Geussler, Dr. Otto, 4, Princess Road, Crumpsall, Manchester, Chemist.
- Hanna, W. W., 36, Purchase Street, Boston, Mass., U.S.A., Aniline Colour Manufacturer.
- Hardy, Chas. H., c/o Reckitt and Sons, Ltd., Hull, Chemist.
- Hesse, Bernhard C., 137, West 110th Street, New York City, U.S.A., Chemist.
- Hulton, Henry F. Everard, 11, Colinette Road, Putney, S.W., Chemist.
- Jenkins, Chas. D., 8, Grove Street, Winchester, Mass., U.S.A., Chemist.
- Jolliffe, Frank, 79, Amersham Road, New Cross, London, S.E., Chemist.
- Kirkman, Alexander S., 52, Bridge Street, Brooklyn, N.Y., U.S.A., Soap Manufacturer.
- Lee, Ashton, Lawrence, Mass., U.S.A., Manufacturing Chemist.
- Lee, Frank W., Lawrence, Mass., U.S.A., Manufacturing Chemist.
- McCleary, William, 102, Cook Street, Pendleton, near Manchester, Finisher.
- Maisel, Carl, 122, Covert Street, Brooklyn, N.Y., U.S.A., Pharmaceutical Chemist.
- Menzies, David, 11, Camphill Avenue, Langside, Glasgow, Analyst.
- Moore, Leslie R., 173, Oakleigh Road, Newton, Mass., U.S.A., Chemist.
- Moulton, Jno. Fletcher, K.C., M.P., F.R.S., 57, Onslow Square, London, S.W., Barrister-at-Law.

- Nash, W. A., Corn Exchange Bank, New York City, U.S.A., President, Corn Exchange Bank.
- Neech, Herbert R., c/o The Rio Tinto Co., Ltd., Casa Colon, Huelva, Spain, Chemical Engineer.
- Norton, Arthur Leavitt, 36, Purchase Street, Boston, Mass., U.S.A., Dyestuff Merchant.
- Oakes, F. J., jun., 147, Milk Street, Boston, Mass., U.S.A., Secretary, Oakes' Manufacturing Co.
- Render, Frederick, 2, Albert Street, Manchester, Explosives Manufacturer.
- Revis, Cecil, 77, King Street West, Hammersmith, W., Analyst, Welford and Sons, Ltd.
- Schweitzer, Jacob, 60th Street, near 14th Avenue, Brooklyn, N.Y., U.S.A., Chemist.
- Shaw, John, 40, India Wharf, Boston, Mass., U.S.A., Manufacturing Chemist.
- Sheldon, John C., Dartmouth Villa, Chester Road, Erdington, near Birmingham, Analytical Chemist.
- Speyer, James, c/o Speyer and Co., 24, Pine Street, New York City, U.S.A., Banker.
- Talbot, Prof. Henry P., Mass. Institute of Technology, Boston, Mass., U.S.A., Professor of Inorganic Chemistry.
- Taylor, Wm. H., 4a, Durlston Road, Northwold Road, Upper Clapton, N.E., Chemist.
- Todhunter, B. E., West Hydraulic Engineering Co., 23, College Hill, London, E.C.
- Whiteside, Harold, 74, Holly Avenue, Jesmond, Newcastle-on-Tyne, Colour Maker.
- Williams, Gerald W., South Rose Deep, Ltd., Box 21, Germiston, Transvaal, Metallurgical Chemist.
- Wills, William H., 162, Main Street, Waltham, Mass., U.S.A., Dyer.
- Hunter, Prof. A. G. Kidston; all communications to P.O. Box 164, Dunedin, New Zealand.
- Hyde, B. T. B., 1/o Washington Street; 80, West Street, New York City, U.S.A.
- Johnson, Jesse E., 1/o Montreal; Vaudreuil Street, P.Q., Canada.
- Lawson, Wm., 1/o Utah; c/o The Sterling Sugar Co., Sterling, Colo., U.S.A.
- Noake, Frank; Journals to S. S. Mond Gas Works, Dudley Port, Tipton.
- Norton, Dr. T. H., 1/o Mamouret-ul-Aziz; American Consul, Smyrna, Turkey-in-Asia.
- Park, James, 1/o Garngad Hill; Millburn Chemical Works, 51, Millburn Street, Glasgow.
- Parker, Chas. E., 1/o Vine House; Penketh, Wirrington, Dr. H. H., 1/o Cambridge, Mass.; Garngad Hill, 68, Breslau, Germany.
- Rawson, Christopher, 1/o Ludwigshafen; retain Journals.
- Ross, Herbert W., Journals (temporary) to 1302 Street, Oakland, Cal., U.S.A.
- Schwarz, G. A., 1/o 63; 60, Wall Street, New York City, U.S.A.
- Shuler, D. P., 1/o Mine La Motte; 495, Cass Avenue, Detroit, Mich., U.S.A.
- Slosson, E. E., 1/o Laramie; c/o "New York Independent," New York City, U.S.A.
- Sparre, Fin., 1/o Jackson Street; 1810 Washington Street, Wilmington, Del., U.S.A.
- Stewart, Samuel, 1/o Wallington; 138, Marine Parade, Brighton.
- Tighe, Arthur, 1/o London; Ravensworth, Glebe Point, Sydney, N.S.W.
- Watson, Herbert J., 1/o Mansfield; 35, Park Street, Widnes, Lancashire.
- West, Leonard, 1/o Uttoxeter New Road; 10, Tipton Lane, Derby.
- Wray, O. J. P., 1/o British Alizarine Co.; all communications to Hazlemere, Coleraine Road, Blackpool, S.E.

Changes of Address.

When notifying new addressees, members are requested to write them distinctly, and state whether they are temporary or permanent. Multiplication of addresses is also to be avoided as tending to create confusion. When sending subscriptions, the use of the form attached to the application helps in the verification of addresses, on which the safe delivery of the Journal depends.

- Barnes, Edw. A., 1/o Transvaal; 194, Hammersmith Road, London, W. (temp.).
- Blumenthal, L., 1/o Lever Street; 10, Clifton Street, Crumpsall, Manchester.
- Blundstone, Edwin R., 1/o Great Smith Street; 77, York Street, Westminster, S.W.; Journals as before.
- Butler, W. Waters; Journals to c/o Mitchells and Butlers, Ltd., The Brewery Library, Cape Hill, Birmingham.
- Carhart, Dr. C., 1/o Niagara; retain Journals.
- Crosfield, A. L.; Journals to c/o Prof. B. Moore, Biochemical Dept., The University, Liverpool.
- Duncan, Jas.; Journals to 52, Shakespeare Street, Hove, Sussex.
- Dvorkovitch, Dr. P., 1/o Bevis Marks; 45, St. Mary Axe, London, E.C.
- Ede, H. E., 1/o Iquique; 251, School Road, Sheffield.
- Feilmann, Dr. E., 1/o 112; 7, Alexandra Road, Wimbledon, S.W.
- Fox, J. Wesley., 1/o 7; 2, Bushell Street, Wapping, E.
- Frew, John; Journals to Ruchill Chemical Works, Glasgow.
- Harris, Leonard A.; Journals to Mallinckrodt Chemical Works, William Street, New York City, U.S.A.
- Hebden, John C., 1/o Exchange Place; P.O. Box 824, Providence, R.I., U.S.A.

Change of Address Required

- Kneeland, F. L., 1/o 21, Park Row, New York City, U.S.A.

Deaths.

- Ackroyd, Wm., Crossley Street, Halifax, Yorks.
- Glatz, Jos., 485, Kent Avenue, Brooklyn, N.Y., Jan. 26.
- Williamson, G. N., of 14, Dey Street, New York City, U.S.A.; at Rome, April 27.

London Section.

THE MECHANICS OF FIRE.

BY HENRY E. ARMSTRONG, PH.D., LL.D., F.R.S.

(This J., May 15, 1905, 473—482.)

ERRATUM.

Mr. R. J. FRISWELL's remarks in discussion on col. 1, par. 4, line 4 *seq.*, should read as follows:—
"By reducing the products so formed with zinc he was able to show that the effect of the oxidant been to introduce a large number of hydroxyl groups into the coal."

New York Section.

Meeting held at Chemists' Club, on Wednesday, April 19th, 1905.

MR. RUSSELL W. MOORE IN THE CHAIR.

PAINT CONDITIONS EXISTING IN THE NEW YORK SUBWAY.

BY MAXIMILIAN TOCH.

The steel structure of the New York Subway was painted for the purpose of protection against rust, and the engineers in charge of this were guided by their past experience, and endeavored to specify what they thought would last longest. It must be taken into consideration from the outset that this investigation is means any reflection on the specifications as they are written, nor in the remotest sense a criticism of the materials that were used.

It was stated, the steel arrived on the work treated with a coat of pure red lead and pure linseed oil, and had been placed in position, competent men were put in charge; the structure was cleaned and given one heavy, continuous coat of pure red lead, and pure linseed oil, specifications calling for 33 lb. of red lead to the lb. of linseed oil. All the exposed steel work was treated with pure white lead and linseed oil as a final coat. Chemical analyses were frequently made of the paint materials.

A paper on the Chemistry of Paints and Pigments, published in the *Journal*, Jan. 31, 1902, pp. 104-5, will be seen from the photomicrographs of a film of red lead. These were taken from the pots of two painters, one of whom was painting the elevated railroad structure, and the other the exposed steel work on the Subway at the Grand Central Station. I was previously given a sample of red lead and linseed oil, of which I made a chemical analysis in order to be sure that the materials were absolutely pure, which turned out to be the case; I then discourse on this subject before this Society, and my objections to this mixture (*loc. cit.*).

The work on the 50th Street section was completed first, and after two years and three months after the application of a coat of paint it was noticed that at this section, the paint appeared to be in good condition, it showed no air line cracks, and if a knife blade were inserted between these cracks large sheets of paint were pulled off, the remaining paint carrying rust varying in thickness. The engineers in charge very kindly granted me permission to make an investigation as to the cause of this oxidation of the paint, and it gives me very much pleasure to report publicly on this subject with the consent of the engineers.

The rust underneath the paint appeared under the microscope to be distributed in a laminated condition, and was graphically described, my analyses showed that the oxidation was progressive in leaf-like layers. The rust alternate light red-brown and dark brown layers, the brown layers having the composition equivalent to $\text{Fe}_2\text{O}_3 \cdot 2\text{H}_2\text{O}$, and the blackish brown, $\text{Fe}_3\text{O}_4 \cdot \text{H}_2\text{O}$. The percentage of iron varied between 55.6 and 64.9 per cent. The water between 5.87 and 6.8 per cent.

It then, would preclude the possibility of mill scale causing the oxidation, but from the photomicrographs already referred to, it can readily be seen that the rust of red lead were so large and the air bubbles which were so thoroughly encysted that the material was probably acted as a rust producer instead of preventive.

A paper before the American Chemical Society, March 20, 1903, I gave it as my opinion that a film of linseed oil is not porous, excepting for the bubbles which may be bedded in it, but that any dried linseed oil subjected to moisture forms with it a colloidal solution, and the moisture is carried through on to the surface of the metal. We then have two films, which, beyond a doubt, have sufficient inherent tendency to produce oxidation under the proper conditions,

and, granted that the percentage of carbon dioxide in the air of the tunnel is not beyond the normal, the fact that carbon dioxide, together with moisture would cause this progressive oxidation is sufficient warrant for the discontinuance of paints that are not moisture and gas proof. Dr. Lewkowitsch demonstrated in his Gante lectures that the fats and fatty oils hydrolysed with water alone, and linseed oil is hydrolysed to a remarkable degree in eight hours when subjected to steam. It can, therefore, be inferred that water would act on linseed oil without the presence of an alkali, and calcium added to water simply hastens the hydrolysis, leaving the inference that lime is the catalyser. This, then, bears out my previous assertion that a film of linseed oil (linoxyn) and water combine to form a semi-solid solution similar in every respect to soap, and, inasmuch as we have lime, iron, lead and similar bases present in many paints, it is almost beyond question that these materials aid in the saponification of oil and water.

For nearly three months, beginning with January and ending with March, I kept a strict record of the temperature, humidity, vapour density and dew point of the air in the Subway, and I particularly selected these months as being the driest in this climate. Our winters here, excepting on such days when we have a thaw and a rain, are considerably below normal in point of humidity, and from the list which I here append, it will be easily seen that condensation on the posts of the Subway is normal and a high dew point is abnormal. For this purpose I carefully registered the conditions according to Lambrecht polymeter, and though the temperature of the Subway may have been on a very dry day, say, 50°, if it were sufficiently cold outside, the post itself may have been 40°, or lower, owing to its direct conductivity with the outer air, and in such a case condensation would take place on the posts even though the relative humidity and dew point were not excessive.

* Bad weather, rain.

† Bad weather, snow.

It will, therefore, be seen that a pigment compound with linseed oil is not fit for subterranean work.

We have evidently learned a very valuable lesson on the action of linseed oil paint in the New York Subway, and if it has done nothing more, it has, at least, taught chemists and engineers that, in places where there is vapour pressure, condensation and abnormal humidity, a linseed oil paint and a pigment are useless. A paint, therefore, which will not saponify or hydrolyse should be used for all subterranean work.

From the examination made of the rust taken from the Subway, I cannot draw any average of composition. The wide differences are due to the fact that some of these particles of rust were carefully selected as to colour, the light ones having the probable formula of $\text{Fe}_2\text{O}_3 + 2\text{H}_2\text{O}$. The darker ones $\text{Fe}_3\text{O}_4 + \text{H}_2\text{O}$. The percentages of moisture vary between 5.87 and 6.80, and from the laminated structure of the rust and the figures obtained, it is possible to deduce that the rust in the Subway is a mixture of $\text{Fe}_2\text{O}_3 \cdot 2\text{H}_2\text{O} + \text{Fe}_3\text{O}_4 \cdot \text{H}_2\text{O}$.

There must be no misunderstanding on the subject of any existing danger of continued oxidation to the posts in the Subway for the following reasons, that the present paint is being scraped, and that the factor of safety is so great that even if the posts were left uncoated, it would be very many years before any appreciable difference could be detected. At the same time, it is an object lesson to us all on progressive oxidation, and in connection with this I have lately examined the steel pier at Atlantic City, N.J., which was erected on the 3rd of April, 1898, and from which I picked with a pen knife in the places covered by the mean tide, scales from $\frac{1}{4}$ in. to $\frac{3}{4}$ in. in thickness. A pier of this kind is absolutely no test for paint, because the cyclic oxidation produced by salt water is similar to that of carbon dioxide, and a great number of the salts, ammonium chloride in particular, will produce progressive oxidation which in time may probably destroy the object itself.

I wish to express my thanks to the engineers who have permitted me to make this investigation, and have rendered me every assistance possible.

PROF. A. SMITHells IN THE CHAIR.

NATURAL AND INDUCED DRAUGHT.

BY JOHN W. COBB.

Many papers have been submitted in recent years to many societies on this subject, and a plea is necessary for

adding one to the number; I find justification in the what one-sided treatment which, to my mind, has often given to the subject. One would suppose that was a consensus of opinion that natural draught, created by a chimney, was of necessity as wasteful as it is antiquated, when compared with artificial draught created by a fan. Let us dispassionately look at the facts ascertain so far as we can the limits within which a combination of that venerable antique, the chimney-steeple justified.

And first let us consider how the chimney does its

If we suppose a U-tube $a b c d e$ (Fig. 1), of which is filled with cold gas, and $b a c c$ with hot gas, they have a moving force on the gas in the tube in the direction $c e a$, that of the arrow, which moving force will be excess in weight of the column $c d$ over that of the column $a b$. So in a chimney, the moving force is the excess weight of a column $C D$ (Fig. 2) of cold air, reaching

the level of the combustion grate C to that of the chimney-top B or D , over the weight of the column $A B$ of hot gas, reaching from the grate level A to the chimney top B .

For the quantity of air which this force can move through the chimney, in the ideal frictionless system, the following formula is calculated:—

$$(i.) \quad Q = S d_0 \sqrt{\frac{2 g a L (t_1 - t)}{1 + a t_1}}$$

(see Appendix L, page 532), where

Q = weight of air in unit time.

S = cross-section of chimney, L = height.

d_0 = density of air at temperature 0°C .

t_1 = temperature inside chimney, supposed uniform.

t = outside temperature.

a = co-efficient of expansion of air.

g = acceleration due to gravity.

or making $S d_0 \sqrt{2 g a} = K$ (constant)

$$(ii.) \quad Q = K \sqrt{L} \sqrt{\frac{t_1 - t}{1 + a t_1}}$$
